Genius conducting Taste to the Temple of
ARTS & SCIENCES.

THE COMPLETE

DICTIONARY

OF

ARTS and SCIENCES.

IN WHICH THE WHOLE CIRCLE OF

HUMAN LEARNING

IS EXPLAINED,

And the DIFFICULTIES attending the Acquiſition of EVERY ART,
Whether LIBERAL or MECHANICAL, are Removed,

IN THE MOST EASY AND FAMILIAR MANNER.

Among the various Branches of LITERATURE explained in this WORK are the following, viz.

AGRICULTURE
ALGEBRA
ANATOMY
ARCHITECTURE
ARITHMETIC
ASTRONOMY
BOTANY
CATOPTRICS
CHEMISTRY
CHRONOLOGY
COMMERCE
CONICS
COSMOGRAPHY
DIALLING
DIOPTRICS
ETHICS
FLUXIONS
FORTIFICATION
GARDENING
GAUGING
GEOGRAPHY
GEOMETRY
GRAMMAR
GUNNERY
HANDICRAFTS
HERALDRY
HISTORY
HORSEMANSHIP
HUSBANDRY
HYDRAULICS
HYDROGRAPHY
HYDROSTATICS
LAW
LEVELLING
LOGIC
MARITIME AND MILITARY AFFAIRS
MATHEMATICS
MECHANICS
MERCHANDIZE
METAPHYSICS
METEOROLOGY
MUSIC
NAVIGATION
OPTICS
PAINTING
PERSPECTIVE
PHARMACY
PHILOLOGY
PHILOSOPHY
PHYSIC
PNEUMATICS
RHETORIC
SCULPTURE
SERIES
STATICS
STATUARY
SURGERY
SURVEYING
THEOLOGY, &c.

The THEOLOGICAL, PHILOLOGICAL, and CRITICAL BRANCHES, by
The Rev. TEMPLE HENRY CROKER, A. M.
Chaplain to the Right Honourable the Earl of HILLSBOROUGH.

The MEDICINAL, ANATOMICAL, and CHEMICAL,
By THOMAS WILLIAMS, M. D.

The MATHEMATICAL
By SAMUEL CLARK,
Author of an Eaſy Introduction to the Theory and Practice of Mechanics.

AND THE OTHER PARTS BY
Several GENTLEMEN particularly converſant in the Arts or Sciences they have undertaken to explain.

LONDON: Printed for the AUTHORS,
And Sold by J. WILSON & J. FELL, Pater-noſter Row; J. FLETCHER & Co. St. Paul's Church-yard;
J. COOTE, Pater-noſter Row; Meſſ. FLETCHER & HODSON, Cambridge; and W. SMITH & Co. Dublin.

ADVERTISEMENT.

THE various Improvements lately made in almoſt every Branch of Learning will, we preſume, be a ſufficient Reaſon for compiling a *New Dictionary of Arts and Sciences*; in which we propoſe to preſent the Reader with a complete *Body of Literature*, enriched with all the Diſcoveries of the Learned in Europe.

It ſhould alſo be remembered, that ſince the publication of any Work of this Kind, the *Society for the Encouragement of Arts, Manufactures, and Commerce*, has been inſtituted; and in conſequence of the large Premiums and Bounties given by that generous Body, a great number of Improvements in ſeveral uſeful Arts have been made, and many curious Machines conſtructed, Models of which are now depoſited in the Cuſtody of the Society, for the Benefit of Mankind. We therefore propoſe to give, in the Courſe of this Work, elegant Deſigns and accurate Deſcriptions of the moſt uſeful of theſe Machines, and which, we humbly hope, will be conſidered as a very uſeful Part of our Undertaking.

We are therefore perſuaded that the different Dictionaries already extant, will be no Objection to the Work now offered to the Public; eſpecially as their Imperfections are ſufficiently known in the Republic of Letters. It is not, however, our Intention to depreciate the Works of others in order to recommend our own; but we will venture to promiſe, that every thing valuable in Mr. Chambers' Cyclopedia, and the other Works of that Kind, particularly the Encyclopedie publiſhed at Paris, ſhall be contained in this Dictionary, augmented with the Diſcoveries and Improvements made ſince theſe Works were compiled. At the ſame time we would beg Leave to declare, that theſe Books are ſo far from being the only ones uſed in compoſing this new Dictionary of Arts and Sciences, that we have extracted the greater Part of our Articles from Original Authors; being ſenſible that the Authority of any Work of this Kind muſt, in a great meaſure, depend upon the Reputation and Merit of the Writers from whom it is collected: And our Readers may be aſſured, that in ſuch Articles as are extracted from Foreign Authors, all the Difficulties and Obſcurities that occur in the Original will be removed and explained in their reſpective Tranſlations.

We ſhall alſo endeavour, as far as the Nature of our Plan will admit, to give entire Syſtems of the moſt uſeful Branches of Mathematical Learning, in order to render this Work as independent of others as poſſible; and at the ſame Time to inveſtigate carefully the more ſublime Parts of that Science, ſuch as the Aberration of Light, the Lunar Theory, &c. according to the lateſt Improvements.

Daily Experience ſufficiently demonſtrates how difficult it is for any Author to explain fundamentally a ſingle Art or Science, even when it has been the principal ſtudy of his Life; how great then muſt the Difficulty prove to explain the whole Circle of Arts and Sciences? We were ſufficiently aware of this enormous Burden, and therefore thought proper to divide it, that we might be the better enabled to ſupport ſo great a Weight. Accordingly a ſufficient Number of Gentlemen are engaged in the preſent Undertaking, and each Member employed in executing the Part he thoroughly underſtands; and conſequently is not only acquainted with what the Ancients and Moderns have written on the ſame Subject, but capable of adding to theirs his own Acquiſitions. By this Means the principal Articles will be treated with more Method and more Certainty; carried to a greater Extent, and executed with greater Preciſion, than thoſe of any other Work in the Engliſh Language. It ſhall be our principal Concern to collect Facts, compare Experiments, confute Errors, aſcertain Diſcoveries, and contrive Methods for exciting Perſons of Genius to ſtrike out new Paths of Science, and extend the preſent Boundaries of human Knowledge.

For this purpoſe we ſhall prefix to the Principles of the Liberal Arts a ſuccinct Account of their Riſe and Progreſs, that Perſons of Capacity may have no Reaſon for the future to miſemploy their Time in ſearching after Things already known; nor Pretenders to Science be any longer capable of impoſing on the World, as Diſcoveries of their own, what the Induſtry of others had before explored.

But the greateſt Difficulty attending the preſent Undertaking occurs in the Part relating to the Mechanic Arts. Books afford very little Aſſiſtance here; we have been therefore obliged to have recourſe to Workmen themſelves; who being often incapable of deſcribing with Preciſion the Arts they profeſs, it became neceſſary for us to clear up and methodize their Thoughts; learn the proper Terms of their Art; define them; and deſcribe the various Inſtruments and Machines uſed in their reſpective Occupations.

This has rendered it neceſſary to augment the Number of Plates, as the bare View of an Object often conveys more Information than whole Pages of Words. And though we have taken the greateſt Care to inſert no Figures but what were abſolutely neceſſary, we could not contain the Whole in leſs than ONE HUNDRED AND FIFTY COPPER-PLATES. How imperfect then muſt a Work of this Nature be which has only Thirty!

From this ſhort Sketch the Reader will be able to form ſome Idea of the preſent Undertaking; and we would humbly hope, that its Utility will recommend it to the Favour of the Public. But whatever Fate may attend our Labours, we ſhall always enjoy the inward Satisfaction of having ſpared no Pains to render this Work a *Complete Syſtem of Human Learning.*

We ſhall only add, that as Care will be taken to render the Work complete of itſelf, no *Supplement* will be neceſſary. And we need not point out the Trouble and Inconvenience of a double Alphabet, with which almoſt every Work of this Kind hitherto extant is incumbered.

LIST of SUBSCRIBERS.

MR. John Abbot
— Abedward
— John Ackarley
Miſs Adams
Mr. William Adams
— James Adams
Reverend Dr. Adams
Clarke Adams, eſq. Eaſt Hadden, Northamptonſhire
Mr Adcock of Englefield, Berks

⁎ The Proprietors hope that none of their Subſcribers will take it amiſs in not finding their names inſerted in the above liſt; ſince they have not been able, with the utmoſt care, to obtain the names of half the number of thoſe who favoured this work with their ſubſcription.

PREFACE.

A Small degree of reflection will be ſufficient to convince us, that the Arts and Sciences are all connected together, form one general concatenation, and, therefore, mutually aid and aſſiſt one another. But however obvious this truth may appear, it will be no eaſy taſk to reduce the various branches of human knowledge into a ſingle ſyſtem; for we even find it very difficult to reduce any one of the Arts or Sciences to a few rules, or general principles. However, as an enquiry of this kind muſt be of the greateſt utility, by affording us a philoſophical liſt of the Arts and Sciences, let us ſee how far it may be effected; and in order to this previouſly enquire into the origin, generation, or production of human knowledge; its cauſes, ſigns, and the formation of our ideas.

All human knowledge may be divided into direct and reflex. We receive the former immediately by the ſenſes, without the leaſt exertion of the will; it comes uncalled and unobſtructed to the mind: the latter the mind acquires by operating on the direct, that is, by uniting, ſeparating, arranging, or combining.

But as all our direct knowledge flows in by the ſenſes, ſo, conſequently, all our ideas are owing to our ſenſations. This was one of the principles of the philoſophers in the earlieſt times; and the ſchoolmen received it as a maxim, becauſe of its antiquity, rather than from its being founded in truth; for they would have as warmly defended ſubſtantial forms and occult qualities.

This truth, on the revival of philoſophy, had the misfortune of being overlooked, by ſtanding among a number of abſurd opinions, and was proſcribed with them; nothing being more dangerous to truth, or preventive of its being ſeen, than its keeping company with error. The ſeducing doctrine of innate ideas, recommended perhaps the ſtronger by its novelty, was adopted, and long prevailed over this axiom of the ſchoolmen; nor does it even now want its defenders: ſo difficult is it for truth to regain her ſeat, when once dethroned by prejudice or ſophiſtry. At preſent, however, it is almoſt univerſally acknowledged, that the ancients were here in the right: nor is this the only point wherein the moderns begin to do them juſtice.

There is nothing more certain than the exiſtence of our ſenſations; and to prove that they are the genuine foundations of all our knowledge, it will be ſufficient to ſhew that they poſſibly may be ſo; for in ſound philoſophy, deductions founded on facts and acknowledged truths, are preferable to what reſts only on hypotheſes, however ingenious. Why ſhould we imagine that man has pure intellectual ideas born with him, when he need only reflect upon his own ſenſations in order to form them? The following particulars will, we are perſuaded, ſufficiently ſhew, that all our intellectual ideas owe their origin to reflection.

The firſt thing taught us by our ſenſations, is our own exiſtence, which cannot be diſtinguiſhed from them; and, conſequently, our primary reflections revert back upon ourſelves, or that thinking principle which conſtitutes our nature, and no way differs from ourſelves.

A ſecond thing taught us by our ſenſations is the exiſtence of external objects, and among the reſt, that of our own bodies; which are, in a certain ſenſe, external to us: this truth we acquire even before we diſtinguiſh the ſeparate nature of the thinking principle within us.

The effect which theſe innumerable external objects have upon us, is ſo ſtrong, ſo conſtant, and ſo attractive, that after our ideas of reflection have called us into ourſelves, thoſe of ſenſation, which every way beſet and ſurround us, preſently force us outwards; and detain us from that penſive ſolitude, in which we ſhould otherwiſe remain.

The mutiplicity of theſe ſenſations, the concurring agreement of their evidence, the degree we obſerve in them, the involuntary affections they excite in us, compared with the voluntary controul we have over our ideas of reflection, which operate only on our ſenſations; produce in us an irreſiſtible impulſe to aſcertain the real exiſtence of external objects, and to regard them as the cauſe of our ſenſations. Many philoſophers have held this impulſe to be the effect of a Supreme Being, and the moſt convincing argument of the real exiſtence of an external world.

But as we know of no relation between any ſingle ſenſation, and the object thus ſuppoſed to occaſion it, we cannot reaſon from the one to the other: and nothing but a kind of inſtinct, more certain than even reaſoning itſelf, would oblige us to draw ſo remote a concluſion. But this inſtinct is ſo ſtrong in us, ſuppoſing it to ſubſiſt for a moment, whilſt all external objects were annihilated, that even the reproduction of thoſe objects could not add to its ſtrength. It is therefore highly reaſonable to conclude, that our ſenſations actually have the external cauſe ſuppoſed; ſince the effect of that cauſe could no way differ from what we find in fact. To judge otherwiſe, would be acting like Montaigne's philoſophers, who being deſired to aſſign the principles of human actions, replied, they doubted whether any human being exiſted. For fear, therefore, of obſcuring a truth acknowledged even by the ſceptics, when not heated in diſpute, we ſhall leave the metaphyſicians to diſcover the tranſcendental cauſe of this effect, and, if poſſible, to aſſign the progreſs of the ſoul in her firſt ſallies; whilſt attracted out, and, at the ſame time, detained within, by a croud of perceptions; whilſt ſolicited on one ſide to external objects, and, on the other, chained to the body, ſhe has only a narrow ſphere left her to act in.

Our bodies, of all external objects, affect us moſt, as they belong more immediately to us. We are no ſooner ſenſible that our body exiſts, but we are ſollicitous to guard it from ſurrounding dangers. It is expoſed to a thouſand wants, and ſo extremely ſenſible of the action of other bodies, that without our attention it would ſoon be deſtroyed. All external bodies, indeed, do not affect us diſagreeably; the action of ſome procure us pleaſure; but ſuch is the condition of human nature, that we have a quicker ſenſe of pain than of pleaſure: the latter therefore ſeldom compenſates for the former.

Certain philoſophers indeed vainly maintained that pain was not an evil, and ſuppreſſed their cries in the midſt of torments; whilſt others as vainly placed ſupreme happineſs in voluptuouſneſs, which they notwithſtanding avoided, for fear of its conſequences. But all of them would have ſhewn more knowledge of human nature, had they reſtrained the ſovereign happineſs of this life to an exemption from pain; and allowed that we can only approach this happineſs, in proportion to our watchful circumſpection.

Such natural reflections infallibly ariſe in the breaſt of every man left to himſelf, free from the prejudices of a wrong education, or perverted ſtudy. They follow as conſequences of the firſt impreſſions we receive from objects, and may be placed among thoſe early emotions of the ſoul, which are ſo valuable to the truly wiſe, and ſo deſerving of obſervation; though rejected or diſregarded by vulgar philoſophers, whoſe principles they almoſt univerſally contradict.

The neceſſity we lie under of preſerving our bodies from pain and deſtruction, obliges us to examine what external objects may prove uſeful or hurtful to us; in order to ſecure the one, and avoid the other: but as ſoon as we begin to conſider theſe objects, we diſcover among them numerous beings, entirely like ourſelves in appearance; their form exactly reſembling ours; and having, ſo far as at firſt appears, the ſame perceptions: whence we are led to conclude they labour under the ſame wants, have the ſame appetites, and the ſame deſire of gratifying them; and conſequently that we might reap great advantages by uniting ourſelves with others of our ſpecies, in order to diſcover what things in nature tend to our preſervation or detriment. The communication of ideas is the principle and ſupport of this union; which neceſſarily requires the invention of ſigns: and this is the principle on which ſociety was firſt formed, and language introduced.

This communication, which many very ſtrong motives oblige us to hold with others, ſoon enlarges our ideas, and produces new ones very different in all appearance from thoſe we ſhould have had without ſuch aſſiſtance. We ſhall leave philoſophers to judge whether this reciprocal communication, together with the reſemblance we find between our own ſenſations and thoſe of the reſt of our ſpecies, does not greatly contribute to ſtrengthen our unſurmountable propenſity to aſcertain the exiſtence of all the objects that ſtrike us.

And certainly the pleaſures and advantages flowing from this communication, either by imparting our ideas to others, or by adding thoſe of others to our own, ſhould oblige us to maintain an intimate union in ſociety; and induce us to render it as mutually uſeful as poſſible.

But each member of ſociety ſeeking his own perſonal advantage, and finding an equal deſire in others to do the ſame; all of us cannot poſſibly receive an equal ſhare, tho' we have all an equal right: and hence a right ſo juſt is preſently invaded by that barbarous one of inequality, or the law of force; the uſe of which ſeems to level us with brutes, and is extremely difficult not to abuſe. The ſtrength given to ſome by nature, doubtleſs to be employed for the ſupport and protection of the weak, becomes the means of oppreſſion: but the more violent this oppreſſion proves, the leſs patiently the weak endure it: from a perſuaſion that they are not obliged to ſubmit to it, by any reaſonable motive. Whence ariſes our notion of injuſtice, and of moral good and evil; the principle of which has been ſo much ſought by philoſophers; whereas it is the voice of nature found in all men, and extending even to ſavages. This is the natural law we find in ourſelves, and the origin of the earlieſt laws founded by mankind. Even without theſe laws this ſole voice of nature is ſometimes ſo ſtrong, as either to prevent, or, at leaſt, to reſtrain oppreſſion within certain bounds. Thus the vices of our own ſpecies produce in us the reflex knowledge of their oppoſite virtues; a knowledge extremely valuable, and which perhaps we never ſhould have acquired, had a perfect harmony and eſtabliſhed equality reigned among the human ſpecies.

From our idea of juſt and unjuſt, and the conſequent moral nature of actions, we are led to examine, what that acting principle within us is, which wills and conceives, We need not examine far into our own bodies, and the ideas we have of them, to diſcover that they are not this principle; becauſe the properties found in bodies have nothing in common with the faculty of willing and thinking: conſequently a human being conſiſts of two principles different in their nature; but ſo united, that the motions of the one have a certain correſpondence with the affections of the other, which we have no power either to ſuſpend or alter: and this correſpondence holds them in reciprocal ſubjection to each other.

This ſubjection, ſo independent of us, together with the reflections we are obliged to make upon the nature of theſe two principles, and their imperfections, raiſes us to a contemplation of an omnipotent intelligent Being, to whom we owe what we are; and who, conſequently, demands our adoration: the knowledge of whoſe exiſtence, therefore, requires nothing more than our own internal ſentiments; even though the univerſal conſent of others, and of all nature itſelf, were wanting. And thus our pure intellectual notions of virtue and vice, the principle and neceſſity of laws, the ſpiritual nature of our ſouls, the exiſtence of God, and our duty towards him; in ſhort, the truths that we have the moſt immediate and moſt indiſpenſible uſe for, are the fruits of our firſt ideas of reflection upon thoſe of ſenſation.

How intereſting ſoever theſe firſt truths may be, with regard to the more noble part of us, the ſoul; the body, to which that part is united, ſoon calls us from them to provide for its numerous wants. To preſerve it, we muſt prevent the dangers that threaten it, or remove the evils it ſuffers. There are two methods of doing this, namely, either by means of our own particular diſcoveries; or of thoſe of others, which we acquire by intercourſe. Such is the origin of Agriculture, Medicine, and all the arts that are abſolutely neceſſary, and which may be juſtly ſtiled the primitive arts of man; and the ſource of all the reſt, though apparently ever ſo remote; as will ſufficiently appear in the ſequel.

In the earlieſt ages, men, by mutually aſſiſting each other with information, or by joint endeavours, ſeem ſoon to have diſcovered ſome purpoſes to which they might apply themſelves: eager to acquire uſeful knowledge, they ſoon quitted idle ſpeculations, examined the different objects of nature, and applied them together, upon perceiving their moſt obvious and ſtriking properties. To this firſt application, a more latent one ſucceeded, ſtill relating to man's neceſſities; and principally conſiſting in a deeper conſideration of ſome leſs properties, in the alteration and decompoſition of bodies, and the uſes that may be thence derived.

But by whatever method the firſt of our ſpecies, and their ſucceſſors, proceeded, inſtigated by an object ſo intereſting as that of their own preſervation; their experience and obſervation of this immenſe univerſe muſt have thrown difficulties in their way, not to be ſurmounted by their utmoſt efforts. Their minds, now accuſtomed to meditation, and deſirous of drawing advantage from it, muſt have found reſource in the diſcovery of ſome merely curious properties of bodies. This is a kind of endleſs diſcovery: and indeed, if an immenſe number of agreeable facts could compenſate the want of a ſingle uſeful truth, we might ſay, that the ſtudy of nature, if it does not afford us neceſſaries, at leaſt furniſhes us with a profuſion of pleaſures; imperfectly ſupplying with a kind of barren ſuperfluity, the place of eſſentials.

Pleaſure holds one of the chiefeſt places in the order of our wants, and the objects of our paſſions. Curioſity is a want to the thoughtful; eſpecially when their reſtleſs deſire is animated by a kind of regret, ariſing from a deſire of entire ſatisfaction: and hence we owe numerous diſcoveries merely pleaſing, to an unhappy impotence of acquiring ſuch as would prove infinitely more uſeful.

Another motive to works of curioſity, is pretence of utility. To have ſometimes found a real advantage from enquiries, where at firſt we did not ſuſpect it, is ſufficient to make us regard all curious enquiries as capable of proving uſeful: which ſhews the origin, cauſe, and progreſs of that ſcience called, in general, Philoſophy, or the ſtudy of nature; comprehending ſo many different parts, that Agriculture and Medicine, which principally gave it birth, are now no more than branches, which, though the moſt ancient, and moſt eſſential, have only been more or leſs eſteemed, as they happened to be more or leſs obſcured, or kept under by the reſt.

In this ſtudy of nature, proſecuted partly from neceſſity, and partly for amuſement, we find that bodies have numerous properties; but generally ſo united in one and the ſame ſubject, that to ſtudy each of them thoroughly, we are obliged to conſider them ſeparate. And by this operation of the mind we ſoon diſcover properties apparently belonging to all bodies; as the power of motion or reſt, and the communication of motion; which are the ſources of the principal changes we obſerve in nature. Upon examining thoſe properties by the ſenſes, eſpecially the communication of motion, we ſoon diſcover another property, whereon they depend, namely, impenetrability; or that kind of force, by which each body excludes all others from the place it poſſeſſes: ſo that two bodies being brought as cloſe as poſſible together, can never occupy a leſs ſpace than that which both of them, conſidered ſeparately, filled.

Impenetrability is the principal property by which we diſtinguiſh bodies from the parts of indefinite ſpace, wherein we ſuppoſe them placed; at leaſt our ſenſes oblige us to judge of them in this manner: and if our ſenſes have deceived us, it is ſo metaphyſical an error, that our exiſtence and preſervation have nothing to fear from it; whilſt by our common manner of conceiving, we conſtantly return to this notion in ſpite of ourſelves.

Every thing induces us to look upon ſpace, if not as the real, yet the ſuppoſed place of bodies; and it is actually by the means of the parts of ſpace, conſidered as penetrable and immoveable, that we acquire the moſt adequate idea we can have of motion: and are therefore impelled to diſtinguiſh, mentally at leaſt, two kinds of extenſion; the one impenetrable, the other conſtituting the place of bodies. And thus, though impenetrability neceſſarily enters the idea we have of the parts of matter; yet this being a relative property, the idea of which we can only acquire by examining two bodies together, we ſoon accuſtom ourſelves to conſider it as diſtinguiſhed from extenſion; which we can mentally abſtract from body.

Bodies, in this new conſideration, we regard only as figured and extended ſpace: which is the moſt general and abſtract light they can be conſidered in: for extent, wherein we diſtinguiſh no figured parts, is no more than a picture without light; where the whole eſcapes us, becauſe we can diſtinguiſh nothing. Colour and figure, properties conſtantly, though differently, reſiding in bodies, help us to diſtinguiſh body from ſpace. Nay, one of theſe properties is ſufficient for the purpoſe; ſo that to conſider body in its mental form, we even prefer figure to colour; either becauſe figure is moſt familiar to us, as being diſtinguiſhable both by the ſight and touch; or becauſe it is more eaſy to conſider the figure of a body without its colour, than the colour without its figure; or, laſtly, becauſe figure ſerves more eaſily, and more preciſely, to determine the parts of ſpace.

Hence we are taught to fix the properties of ſimple figured extent, which conſtitutes the object of *Geometry*; a ſcience, which, in order the better to obtain its end, firſt conſiders extenſion limited by one, then by two, and at laſt by three dimenſions. Theſe three dimenſions conſtitute the eſſence of all mental bodies, or portions of ſpace, terminated every way by intellectual boundaries. And thus, by the ſucceſſive operations and abſtractions of the mind, we diveſt matter of almoſt all its ſenſible properties, in order to examine only its idea. The diſcoveries to which this enquiry leads, cannot fail of being extremely uſeful; eſpecially as it is here unneceſſary to regard the impenetrability of bodies: for when we contemplate their motion, we need only conſider them as figured and moveable parts of ſpace, ſeparate from each other.

But as the examination of figured extenſion preſents numerous poſſible combinations; it is neceſſary to find ſome method of rendering theſe combinations eaſy. And as they principally conſiſt in the calculation, and relation, of the different parts of which we imagine geometrical figures to be formed; this enquiry preſently leads us to *Arithmetic*, or the ſcience of numbers; which is nothing more than the art of finding a ſhort method of expreſſing a ſingle relation, ariſing from the compariſon of many: and the different ways of comparing theſe relations give us the ſeveral rules of Arithmetic.

By carefully reflecting on theſe rules, we eaſily deduce certain principles, or general properties of relations; and by expreſſing theſe relations in a general manner, we diſcover different poſſible combinations: the reſults whereof being reduced to one general form, are no more than Arithmetical combinations, indicated and repreſented by the moſt ſimple and conciſe expreſſion conſiſtent with their generality. The art or ſcience of thus denoting theſe relations is what we call *Algebra.* And though, properly ſpeaking, no calculation can be made but by numbers, nor any magnitude meaſured but extenſion, (for without ſpace we could not exactly meaſure time) yet by conſtantly generalizing our ideas, we arrive at that principal branch of mathematics, and of all the natural ſciences, called *the ſcience of Magnitude in general*; which is the foundation of all the poſſible diſcoveries of quantity, or whatever is ſuſceptible of increaſe or diminution.

This ſcience is the moſt remote end to which the contemplation of the properties of matter can carry us; it being impoſſible to go farther, without entirely quitting the material univerſe. But ſuch is the progreſs of the human mind in its enquiries, that after having generalized its perceptions, ſo as not to be able to extend them further; it returns back by the ſame ſteps, recompoſes its perceptions anew, and gradually forms ideas of ſuch beings as are the immediate and direct objects of our ſenſes. Theſe real bodies being immediately relative to our wants, we are nearly concerned to ſtudy them. Mathematical abſtractions facilitate the knowledge of theſe bodies; and prove uſeful in life only by this application.

Having thus in a manner exhauſted the properties of figured extenſion by our geometrical ſpeculations, we return back, and reſtore to it impenetrability; which conſtitutes phyſical body, and is the laſt ſenſible property of which it was diveſted by our abſtractions. This new conſideration brings with it that of the action of bodies upon one another; for bodies only act by means of impenetrability; whence proceed the *Laws of Motion*, and *Equipollency*, which form the object of *Mechanics*. And hence we carry our enquiries to the motion of bodies impelled even by unknown forces, or motive cauſes; provided the law by which theſe cauſes act, is either known or ſuppoſed.

Returning again to the corporeal world, we preſently perceive the uſe of geometry and mechanics, in making various difficult diſcoveries, founded on the properties of bodies; whence almoſt all the phyſico-mathematical ſciences are deduced; at the head of which we place *Aſtronomy*; a ſtudy, next to that of ourſelves, the moſt worthy of cultivation, on account of the grand ſcene it opens before us. Aſtronomy joining obſervation with calculation, and illuſtrating the one by the other, determines, to a ſurprizing degree of accuracy, the diſtances, and moſt complicated motions of the celeſtial bodies; and aſſigns the forces themſelves by which theſe motions are either produced or altered: ſo that this ſcience may be juſtly regarded as a ſublime, demonſtrative, joint application of geometry and mechanics; and its advancement as an inconteſtible monument of human induſtry.

Nor is the uſe of mathematics leſs conſiderable in examining the terreſtrial bodies that ſurround us. All the properties found in theſe bodies have certain relations to one another, more or leſs ſenſible to us. The knowledge or diſcovery of theſe relations, is almoſt the only object we can arrive at, or need propoſe to ourſelves. It is not to be expected that amuſing, arbitrary hypotheſes can help us to underſtand nature; ſuch knowledge muſt be acquired by conſidering phænomena, comparing them together, and reducing, as far as poſſible, many of them to one, as to a principle. In fact, the more we diminiſh the number of principles in a ſcience, the greater extent we give them. For as the object of a ſcience is neceſſarily determined, the principles applied to that object become ſo much the more pregnant, the fewer, or more general they are made. This art of reduction, which facilitates the diſcovery of principles, conſtitutes genuine theory; and ſhould not be miſtaken for the ſpirit of building ſyſtems; there being often a wide difference between them.

But in proportion as the object conſidered proves more or leſs abſtruſe or extenſive, the reduction we ſpeak of becomes more or leſs difficult; and accordingly we are more or leſs entitled to require it of philoſophers. The magnet, for example, is a ſubject that has been greatly laboured; and ſurprizing diſcoveries, with regard to its properties, have been already made. Its property of attracting iron, and of communicating to that metal the ſame virtue; its turning to the north with a variation ſubject to rules, and affording as ſurprizing a phænomenon as a more exact direction; its dip to the horizon in an angle greater or leſs, according to the part of the earth it ſtands in; are all particular properties, depending probably on ſome one general principle, or cauſe, hitherto unknown. It is an enquiry worthy of philoſophers to reduce, if poſſible, all theſe properties to one; by ſhewing the principle that connects them. But however ſerviceable ſuch a diſcovery might be to the advancement of natural philoſophy, it is not, we fear, eaſy to be made. And the ſame may be ſaid of many other phænomena, whoſe connection perhaps belongs to the general ſyſtem of the univerſe. The only method we can follow, in ſuch laborious, neceſſary, and uſeful reſearches, is to collect as many facts as poſſible; diſpoſe them in a natural order; and reduce them under a certain number of principal facts, of which the leſſer ſhould appear as ſo many conſequences. If at any time we preſume to riſe higher, it ſhould be with a circumſpection becoming ſo feeble an underſtanding as ours.

Such is the plan to be followed in this vaſt ocean of experimental philoſophy; which differs from the phyſico-mathematical ſciences, in being properly no more than a rational collection of experiments and obſervations; whereas the mathematical ſciences, by applying calculation to experience, ſometimes, even from a ſingle obſervation, draw numerous conſequences, approaching in certainty to geometrical truths. A ſingle experiment on the reflection of light, produced the whole ſcience of catoptrics; another on the refraction of light, afforded the theory of the rainbow, the doctrine of colours, and all dioptrics. From obſerving the preſſure of fluids, we derive the laws of their equilibrium and motion. And the ſingle experiment of the acceleration of falling bodies, led to the laws of their falling on inclined planes, and to the doctrine of pendulums.

It muſt indeed be acknowledged that ſome mathematicians have miſapplied Algebra to Natural Philoſophy. Inſtead of proper experiments, they have ſometimes founded their calculations on hypotheſes, commodious indeed for their purpoſe, but often foreign to what is actually found in nature. Algebraiſts have been fond of reducing all to calculation; not excepting the art of medicine itſelf. That complicated engine, the human body, has been treated by computiſts phyſicians, as a ſimple machine, eaſy to analize. It is ſurprizing to ſee theſe authors pretend to ſolve, with a daſh of the pen, ſuch hydraulic and ſtatical problems, as might well employ the whole life of an able geometrician. For our own parts, either more cautious, or more timid, we look upon the greater part of ſuch calculations, and lax ſuppoſitions, as the ſport of fancy, to which nature is not at all obliged to ſubmit; and conclude, that the only true method of philoſophizing in phyſics, conſiſts either in the application of mathematical calculation to experiments; or in ſimple obſervation, conducted by method, and ſometimes aſſiſted by conjectures for farther enquiry; ſcrupulouſly avoiding all arbitrary hypotheſes.

From what has been ſaid we may fix two limits, between which all our certain knowledge of nature appears to be confined: the one is, what we ſet out with, the idea of ourſelves; which leads us to that of an Almighty Being, and our principal duties: the other is, that part of mathematics which has the general properties of body for its object; *viz.* extent and magnitude. Between theſe two limits there remains an immenſe interval, wherein the Supreme Intelligence ſeems willing to exerciſe human curioſity, by the numerous clouds interſperſed, and certain gleams of light breaking out here and there, as if to allure us. The univerſe may be compared to books written with ſublime obſcurity; where the author, ſometimes levelling himſelf to the capacity of his readers, ſeems to perſuade them they nearly underſtand the whole. Happy for us, who enter this labyrinth, if we do not miſtake the path; if we ſhould, the light deſigned to conduct, will often farther miſlead our ſteps.

The little certain knowledge we have, carrying us only to the two limits above mentioned, is far from ſufficient to ſupply our numerous wants. The ſtudy of human nature, ſo neceſſary, and ſo much recommended by Socrates, is an impenetrable myſtery to man aſſiſted only by reaſon. The greateſt genius reflecting upon this important ſubject, ſeldom riſes higher than to know leſs than the reſt of mankind. The ſame may be ſaid of our preſent and future exiſtence; the eſſence of that Being to whom we owe them both; and of the kind of worſhip he requires.

There is therefore nothing more neceſſary for us than a *revealed Religion*, to inſtruct us in eſſential points; and ſerve as a ſupplement to natural knowledge, by opening a ſcene that would be otherwiſe hid from our eyes. But revelation confines itſelf to what is abſolutely neceſſary for us to know; the reſt remains, and will perhaps for ever remain, concealed. A few truths to believe, a few precepts to practiſe, make the ſubſtance of Divine Revelation: but by means of the light it affords, we are more confirmed in many intereſting points, than any of the ſects of mere philoſophers.

With regard to the mathematical ſciences, which conſtitute the ſecond limit of our knowledge, their nature and number ſhould not impoſe upon us. It is principally owing to the ſimplicity of their object, that they are demonſtrable. And as all the branches of theſe ſciences have not their objects equally ſimple, demonſtration (founded on principles neceſſarily true, and ſelf-evident) does not equally belong to them all. Many of them reſt upon principles merely phyſical; ſuch as experiments, or mere ſuppoſitions; and, conſequently, have no more than experimental, or hypothetical certainty. Properly ſpeaking, thoſe only which treat of magnitude, and the general properties of extenſion, as Algebra, Geometry, and Mechanics, can be called demonſtrative. The light which theſe ſciences afford to the mind, has a certain kind of gradation or ſhadowing; the more their object is diſplayed or conſidered in a general abſtract manner, the clearer their principles become. Geometry is more ſimple and abſtract than Mechanics; and Algebra more ſimple and abſtract than either. This is no paradox to thoſe who have ſtudied theſe ſciences philoſophically. The moſt abſtract notions, regarded by the vulgar as the leaſt attainable, commonly afford the cleareſt light: our ideas become obſcure in proportion as we examine the ſenſible properties of matter. Impenetrability, joined to the idea of extenſion, ſeems like adding one myſtery to another. The nature of motion in matter is dark to philoſophers; the metaphyſical principle of the laws of percuſſion is as little known: and the more we examine our idea of matter with its properties, the more obſcure it becomes; and appears to elude our reſearch. We muſt therefore allow that the mind is not equally ſatisfied with evidence, in all the mathematical ſciences.

If we examine theſe ſciences, they will, at firſt view, appear extremely numerous, or almoſt inexhauſtible; but when ranged in order, and formed into a philoſophical liſt, their number falls greatly ſhort of expectation. There are numerous mathematical truths, of which little uſe or application is made. This is, indeed, no argument againſt them, conſidered in themſelves; but even moſt of the axioms of which Geometry boaſts, are only expreſſions of the ſame ſimple idea, under two different ſigns or words. To ſay that two and two make four, gives no more real knowledge than to ſay, two and two make two and two. The ideas of the whole and a part, greater and leſs, are, properly ſpeaking, the ſame individual ſimple idea; becauſe we cannot have the one without the other's preſenting itſelf. Certain philoſophers obſerve, that many errors are owing to the abuſe of words; and perhaps axioms alſo are owing to this abuſe. We do not however condemn their uſe; but only propoſe to obſerve this limitation; which conſiſts in rendering ſimple ideas more familiar by habit; and fitter for the different purpoſes to which they are applicable. The ſame, with proper reſtrictions, may be ſaid of mathematical theorems; which, when fairly conſidered, are reducible to a few primitive truths. If we examine a chain of geometrical propoſitions, ſo deduced the one from the other, that every contiguous two are linked together; we ſhall find, that they are all no more than the firſt propoſition ſucceſſively diſguiſed, in paſſing from one conſequence to the next; the original propoſition being no way multiplied by this concatenation, but only appearing under different forms: as if expreſſed in a language gradually changing by time, and employing a different phraſeology, according to the different ſtages it paſſes through; while each ſtage remains diſcoverable by comparing it with that immediately preceding, but not ſo well by comparing it with one more remote; though all the ſtages depend upon each other, and intended to convey the ſame idea.

We may therefore conſider the concatenation of a number of geometrical truths, as ſo many differently modified tranſlations of the ſame propoſition or hypotheſis. Such tranſlations are indeed highly ſerviceable, on account of the different applications they enable us to make of the theorem they expreſs:

and theſe applications become more or leſs valuable, in proportion to their importance and extent. But as the real merit of ſuch mathematical tranſlation reſides in the original propoſition tranſlated; we perceive how much we owe to thoſe inventors, who, by diſcovering any one of theſe original fundamental truths, from whence numerous others are derived, have truly enriched geometry, and enlarged the ſciences.

There are alſo phyſical truths, and properties of bodies, wherein we find a connection; though all the properties well ranged together, afford us no more than one ſimple truth. If numerous others appear to us as detached, or ſeparate, ſo as to form different truths, this melancholy advantage ariſes from the weakneſs of human underſtanding; our abundance here being only the effect of our want. Electrical bodies, for example, wherein ſo many extraordinary, and, apparently, independent properties have been diſcovered, are, perhaps, the bodies we leaſt underſtand; though we may think we know them the beſt. The virtue they acquire by friction, of attracting lighter bodies, and of producing violent commotions in animals, appear at preſent, as two different things, but would be only one, could we diſcover their primary cauſe. The univerſe itſelf, could we reduce it to a ſingle point of view, would be no more than a ſingle pregnant fact, or immenſe verity.

The different ſciences hitherto mentioned, whether uſeful or agreeable, owing their origin to our wants, are not the only ones we are obliged to cultivate: there are others which relate to theſe, and have therefore been ſtudied with them. We might have deſcribed both ſorts together, had we not judged it more proper and more ſuitable to the philoſophical method of this diſcourſe, firſt to conſider, in an uninterrupted ſeries, the general enquiry men originally made into bodies, though they ſoon joined others to it, and which they ſeem to have purſued in the following order. The advantages they found upon enlarging the ſphere of their ideas, whether by their own endeavours, or the aſſiſtance of others, muſt have led them to think of the uſefulneſs of reducing the means of acquiring and communicating knowledge, to an art; which was therefore invented, and called by the name of *Logic:* an art that teaches us to range our ideas in the moſt natural order; to connect them cloſely together; ſeparate ſuch as envelop too many ſimple ones; examine them on all ſides, and, laſtly, to lay them before others in the moſt intelligible manner. And herein conſiſts the ſcience of reaſoning, which may be juſtly called the key of knowledge; though it did not come firſt in the order of diſcovery. For reaſoning is the free gift of nature to men of genius. The common books of logic prove ſerviceable chiefly to thoſe who might reaſon well without them.

Nor is the ſcience of communicating our ideas confined to the proper arrangement of them; it alſo teaches how to expreſs each idea in the moſt accurate manner, and, conſequently, to aſcertain the marks deſtined to convey them. *Language*, that began with ſociety, was doubtleſs, at firſt, no more than a miſcellaneous collection of marks; and conſequently ſenſible bodies were the firſt objects denoted by names. But, in all probability, languages, at their origin, being ſuited only to the moſt preſſing occaſions, were very imperfect, confined, and ſubject to very few certain rules: the arts and ſciences of abſolute neceſſity might have made a conſiderable progreſs, before any rules of diction or ſtyle were formed. The communication of ideas muſt have been very imperfect during this want of rules, and ſcarcity of words; and have obliged each individual to improve his knowledge by his own labour, without depending much upon that of others. Too facile a communication of knowledge may ſometimes benumb the faculties of the mind, or prevent the exertion of its force: as appears from the extraordinary things performed by perſons born blind and deaf; where we ſee what reſources the mind has, when ſtrongly exerted and brought into action, by difficulties to be ſurmounted.

But as great advantages attend the exchange of ideas, by mutual commerce; no wonder men ſhould endeavour to render this exchange ſtill more eaſy. With this view they began with reducing Signs to Words, which are marks or ſymbols always ready at hand. The order of the generation of words, therefore, followed the order of the operations of the mind; ſo that after individuals, ſenſible qualities came next to be named; which, without having any exiſtence of their own, except in individuals, belong in common to a great number of them; and hence, by degrees, men came to uſe certain abſtract words; ſome ſerving to connect ideas together, others to denote the general properties of bodies, and others to expreſs mere mental notions. All theſe abſtract terms, which children are ſo long in learning, required, doubtleſs, much time to diſcover. But at length the uſe of words being reduced to rule, *Grammar* was formed; which may be conſidered as a branch of Logic. Grammar, aſſiſted by a ſubtile and refined metaphyſics, determines the ſhades, or degrees, of our ideas; teaches us to diſtinguiſh theſe ſhades, by different marks; affords rules for the more commodious uſe of ſuch marks; and, by means of philoſophical ſagacity, in tracing the origin of things, often diſcovers the reaſons of that apparently odd choice, which prefers one ſign to another; and leaves us as little as poſſible to the national caprice, called cuſtom.

At the ſame time that men communicate their ideas, they alſo endeavour to communicate their paſſions. This is performed by means of *Eloquence*, or *Oratory*; which ſpeaks to the paſſions, as Logic and Grammar ſpeak to the underſtanding. Oratory can ſilence reaſon itſelf; and perhaps the great effects which a ſingle orator ſometimes produces upon a whole people, form the moſt glaring inſtance of the power of one perſon over another. And here it is ſurprizing, that men ſhould ever have thought of ſupplying the want of this prodigious talent by rules; as if genius could be reduced to precept. He who firſt pretended that orators owed their power to art, was either no orator himſelf, or very ungrateful to nature; which alone has the power of making an orator. Men are the firſt books to be ſtudied by orators; and the greateſt maſters of the art are the ſecond. All that the moſt illuſtrious writers have left us of the philoſophical and reflex kind, upon the talents of an orator, ſhew us nothing more than the difficulty of becoming one. They were too ſenſible to pretend they could deliver the ſcience; and doubtleſs intended no more than to mark the flats and ſhallows of it. As to thoſe pedantic puerilities honoured with the name of Rhetoric, they ſerve only to render that name ridiculous; they are nothing more to the art of Oratory, than the doctrine of the ſchoolmen is to true philoſophy; and ſeem calculated to give only an extremely falſe and groſs idea of Eloquence.

Man is not contented to live and reign among his cotemporaries alone, but, drawn by curioſity and ſelf-love, eagerly and naturally endeavours to embrace at once the paſt, the preſent, and the future times. We deſire to live with our predeceſſors and ſucceſſors. This ſhews us the origin and deſign of *Hiſtory*; which unites us with paſt ages, by repreſenting their vices, virtues, knowledge and errors; and with the ſucceeding, by tranſmitting our own to poſterity. It is by Hiſtory we learn to eſteem men only for the good they do; and not for the ſeducing pomp that ſurrounds. Sovereigns, who are ſo unhappy as to be excluded from truth on all ſides, may here paſs ſentence upon themſelves beforehand: for Hiſtory is a tremendous, uncorrupt tribunal; which judges their reſembling predeceſſors, juſt as it will do them.

Chronology and *Geography* are two appendages or ſupports of Hiſtory: the one fixing the inhabitants of the earth, in point of time; and the other aſſigning their place upon our globe: they both derive great advantages from the Hiſtory of the earth and heavens; or from hiſtorical facts, and celeſtial obſervations; and may therefore be regarded as deſcendants from Aſtronomy and Hiſtory.

Among the advantages ariſing from the hiſtory of empires and their revolutions, one of the greateſt is to ſee how mankind, ſeparated as it were into numerous large families, formed different ſocieties; how theſe ſocieties gave riſe to different forms of government; and how each people endeavoured to diſtinguiſh themſelves from the reſt by laws, and by particular ſigns, as the means of more eaſily communicating their thoughts: whence aroſe that great diverſity of languages and laws, which, to our misfortune, is become a principal object of ſtudy. Hence alſo we ſee the origin of *Civil Policy*, as a particular and higher kind of morality; to which it is ſometimes difficult to accommodate the difference of common and moral duty. For civil policy, entering into the principal motives of government, aims at diſcovering whatever may tend to preſerve, weaken, or deſtroy a ſtate. This is, perhaps, the moſt difficult kind of ſtudy. It requires a thorough knowledge of mankind, in general, and of the people to be governed, in particular; together with a great compaſs and variety of abilities: eſpecially if the politician would not forget, that the law of nature, being prior to all particular aſſociations, is the firſt law of the people; and that his being a ſtateſman does not preclude his being a man.

Such are the principal branches of that portion of human knowledge, which conſiſts either in the ideas we receive directly by the ſenſes, or in their combination and compariſon; which combination is, in general, called *Philoſophy*. Theſe branches ſubdivide themſelves into ſuch a prodigious number of others, that the enumeration of them belongs rather to the Dictionary itſelf, than to its preface. We began this diſcourſe by conſidering the firſt operation of reflection; which conſiſts in collecting and uniting our direct notions; and have touched upon the different ſciences thence reſulting: but the notions formed by the combination of our primitive ideas, are not the only ſort of which the mind is capable. We are therefore next to conſider another ſpecies of reflex knowledge, conſiſting in the ideas we form to ourſelves, by imagining and comparing things, as they reſemble the objects of our direct ideas: This makes what is called the *Imitation of Nature*, ſo well known, and ſo much recommended, by the ancients. As the direct ideas which ſtrike us with the greateſt force, are thoſe we remember beſt; ſo we endeavour more earneſtly to reproduce them in ourſelves, by imitating their objects. And though agreeable objects ſtrike us ſtronger when real, than when barely repreſented; yet this defect in point of agreeableneſs, is, in ſome degree, ſupplied by the pleaſure we receive from their imitation. On the other hand, though certain real objects excite melancholy or diſtreſsful ſentiments, yet the imitation of them proves more agreeable; by placing us at ſuch a convenient diſtance, that we receive the pleaſure of the emotion, without the diſorder. And in this imitation of all kinds of objects capable of raiſing lively or agreeable ſentiments in us, conſiſts, in general, the imitation of beautiful nature; upon which ſo many authors have wrote, without being preciſe: becauſe, perhaps, it requires exquiſite ſentiments to determine what beautiful nature is; or becauſe the limits to diſtinguiſh what is arbitrary from what is juſt, are not hitherto properly aſcertained, and therefore leave ſome liberty to opinion.

In the liſt of the arts of imitation, *Painting* and *Sculpture* ſtand firſt; as being thoſe wherein imitation comes neareſt to the objects they repreſent; and ſpeaking the moſt directly to the ſenſes. To theſe we may add *Architecture*; an art produced by neceſſity, and perfected by luxury; as having riſen by degrees from cottages to palaces; and being, to a philoſophical eye, no more than an embelliſhed diſguiſe of one of our greateſt wants. The imitation of beautiful nature is here leſs ſtriking, and more confined than in Painting or Sculpture; which indiſcriminately expreſs, without reſtraint, all the parts of beautiful nature, by repreſenting her as ſhe is, either uniform, or with variety: whereas Architecture is conſtrained, in diſpoſing and uniting the different materials it employs, to imitate that ſymmetry, which nature obſerving, more or leſs viſibly, in the ſtructure of each individual, produces ſo fine a contraſt with the beautiful variety of the whole.

Poetry, which ſucceeds to Painting and Sculpture, employs, in its imitations, words ſo diſpoſed as to make agreeable harmony to the ear; but ſpeaks rather to the imagination than to the ſenſes; and thus preſents, in a ſtrong and lively manner, all the objects in the univerſe; and appears, by the glow, motion, and life it gives, to create rather than to paint them.

Muſic, which ſpeaks at once to the imagination and the ſenſes, comes next among the arts of imitation: not that its reſemblance is leſs perfect than theirs, with regard to the objects it would repreſent; but becauſe it has been confined to fewer images. This ſhould not, however, be attributed ſo much to its nature, as to the want of invention and contrivance in moſt of its profeſſors.

Theory and Practice principally diſtinguiſh ſciences from arts; and accordingly, moſt branches of knowledge paſs under one or other of theſe names; though we muſt allow that our ideas are, in this caſe, not hitherto ſufficiently preciſe: for we are often at a loſs to give proper names to ſuch branches of knowledge where ſpeculation is joined with practice. It is frequently diſputed in the ſchools, whether Logic be an art or a ſcience. The queſtion might be eaſily determined by ſaying it is both. It would ſave time, and much altercation, if words could be brought to a clear and preciſe ſignification.

In general, the term Art may be given to any portion of knowledge, capable of being reduced to determinate invariable rules, independent of caprice and opinion. In this ſenſe, ſeveral ſciences, conſidered in their practical uſe, may be termed Arts. There are rules for the operations of the mind, and others for thoſe of the body; the operations of which being confined to external ſubjects, requires no more than the aſſiſtance of the hand to execute them. Hence proceeds the diſtinction between the liberal and mechanical arts; and the preference given to the former, though very unjuſtly in many reſpects. But however ridiculous prejudices may be, every one of them has its cauſe or origin; which philoſophy may diſcover, though unable to correct the abuſe. Violence being the principle which renders the law of equality uſeleſs; the weak, who are always the more numerous, unite to oppoſe it; and by means of laws, and different forms of government, eſtabliſh in ſociety an inequality, of which force is not the principle. This law of inequality once eſtabliſhed, the members unite to preſerve it by reaſon; but cannot prevent a ſecret repining, from the unſurmountable deſire we have of ſuperiority; and therefore ſeek reſource in a leſs arbitrary inequality. And violence being reſtrained by laws, ſo as to afford no means of exerting a ſuperiority; we are obliged to ſeek for a more natural, more pacific, and more uſeful principle of inequality in the difference of the capacities of men: whence the mind is, in ſome meaſure, repaid thoſe advantages uſurped by the body; and the mental talents generally acknowledged ſuperior.

The mechanic arts, depending upon manual operation, and confined to a certain beaten track, are aſſigned over to thoſe perſons whom prejudice places in a lower claſs. Neceſſity, rather than taſte or genius, compelling them to this occupation, became, in time, a cauſe of contempt: ſo detrimental is indigence to thoſe it attends: whilſt the free operations of the mind were left to others who thought themſelves more favoured by nature. But the advantage of the liberal over the mechanical arts, from employing the operations of the mind, and from the difficulty of excelling therein, is ſufficiently balanced by the greater utility moſt commonly ariſing from the mechanic arts. This very utility reduces them to mere mechanical operations; in order to facilitate their practice among a greater number of hands. Thus ſociety may have a juſt regard to its enlightening geniuſes, without debaſing the hands that ſerve it. The diſcovery of the mariner's compaſs is not leſs ſerviceable to mankind, than an explanation of the properties of the needle would be to philoſophy: and according to the above diſtinction, the learning of many is little more than mechanical. What is the real difference between a head furniſhed with a chaos of uſeleſs unconnected facts, and the inſtinct of an artiſan, diſplayed in mechanical execution!

The contempt thrown upon mechanic arts, ſeems, in ſome degree, to have reached their inventors; for the names of thoſe benefactors to mankind are rarely mentioned, while the great deſtroyers of our ſpecies, called conquerors, are univerſally known. Yet ſurely their names, inſtead of being buried in oblivion, well deſerve a place among the happy few who ſtrike out new paths of ſcience.

From what has been ſaid it follows, that the different ways in which our minds operate upon objects, and the different uſes derived from thence, are the firſt means of diſtinguiſhing, in general, our different kinds of knowledge from one another; and that the whole of it relates to our wants, either of neceſſity, convenience, amuſement, real uſe, or capricious abuſe. The more remote our wants are, or the more difficult to ſupply, the more ſlow is the progreſs of our knowledge. What advances would the art of healing have made, to the diſcredit of the ſciences merely ſpeculative, were its principles as certain as thoſe of geometry?

But there are beſides theſe, other ſtrong marks or differences, taken from the manner wherein our knowledge affects us; or the different judgments we make of our ideas. Theſe judgments are denoted by the terms Intuition, Demonſtration, Probability, Sentiment, and Taſte.

Intuition properly belongs to thoſe ideas or propoſitions between which the mind immediately perceives a connection. But where the connection does not appear without the aſſiſtance of intermediate ideas; or when the propoſitions are not found to have an identical agreement with the ſame ſelf-evident principle, but by means of a chain of reaſoning, it is then called Demonſtration. And hence, according to the different nature of men's minds, a propoſition ſelf-evident to one, may be only demonſtrative to another.

Probability takes place principally in hiſtory and hiſtorical facts, and in all events whether paſt, preſent, or future, which, for want of knowing their cauſe, we uſually aſcribe to accident. But though the hiſtory of preſent or paſt tranſactions reſts upon bare teſtimony; yet it often produces as ſtrong a perſuaſion in us, as axioms.

Sentiment is of two kinds; moral and elegant. The firſt regards moral truths, and makes what we call Conſcience; which is a conſequence of the law of nature, and of the ideas we have of good and evil; whence it might be called the evidence of the heart. The ſecond kind of Sentiment is reſtrained to beautiful expreſſion, and the imitation of beautiful nature. This catches, with tranſport, all ſublime and ſtriking beauties; diſcovers, with elegance, ſuch as lie concealed; and rejects all falſe appearances and pretenſions. It often condemns at firſt ſight, without aſſigning the reaſons, which require a conſiderable time to explain, and render intelligible to others.

To this kind of Sentiment we owe what is called Taſte, and Genius; which differ only as Genius is creative, and Taſte judicious Sentiment.

Having thus enumerated the different parts of human knowledge, and their diſtinguiſhing marks, it remains that we form them into a kind of philoſophical table, or ſyſtematical tree of knowledge, which may repreſent them at one view; ſo as to ſhew their origin, relation, and mutual connection. The uſe of ſuch a contrivance will readily appear, but the execution is attended with difficulties. The preceding hiſtory of the origin of our ideas, will indeed aſſiſt us herein; but it would be abſurd and impracticable to follow ſervilely the thread of that hiſtory in forming our plan. A general ſyſtem of the arts and ſciences, is a kind of labyrinth, which the mind enters without knowing what path to take: preſſed by its own wants, and thoſe of the body, it fixes on the firſt objects it meets, proceeds as far as it can, in underſtanding them, but ſoon meets with difficulties to ſtop its progreſs; and either through hope or deſpair of conquering them, ſtrikes into a new path; returns afterwards by the way it went; but no ſooner ſurmounts the firſt difficulties, than it meets with freſh; and courſing about from one object to another, makes upon each a ſeries of different attacks, which the very generation of its ideas neceſſarily interrupts.

terrupts. This diſorder, however philoſophical, in the mind is ſufficient to diſfigure or aboliſh any genealogical view of the arts and ſciences.

In ſhort, the ſyſtem of our knowledge is compoſed of different branches; many of which unite in one point; and conſequently the different turns of men's minds muſt determine the method of tracing the different branches. At firſt many applied themſelves, in concert, to the ſtudy of nature, in order to ſupply their moſt preſſing wants; but when they arrived at parts of knowledge leſs abſolutely neceſſary, theſe were divided, and each purſuing his own, a number of them were almoſt equally improved at the ſame time. But though ſeveral of the ſciences were thus cultivated together, the hiſtorical order in which they muſt be deſcribed, is neceſſarily ſucceſſive.

The ſyſtematical order of our knowledge is a different thing; and conſiſts in contracting the whole of it within the narroweſt bounds poſſible, and placing the reader on an eminence above this vaſt labyrinth, ſo that he may at once view all the principal arts and ſciences; diſcover by a ſingle glance, the objects of ſcience, and the operations to be performed upon them; diſtinguiſh the general branches of knowledge, their points of union, ſeparation, or interſection; and even perceive the ſecret paths that join them. Such a ſyſtem would reſemble a map of the world, and ſhew the principal countries, their ſituation, and mutual relation; together with the direct roads that lead from one to the other; though theſe roads are frequently interrupted, and ſo obſtructed, that none but the reſpective inhabitants, or experienced travellers can know them; nor can they be deſcribed but in the particular maps of each country. The different articles of our Dictionary make ſuch particular maps; and the philoſophical tree, or emblematical ſyſtem, forms the general map of the whole globe.

But as, in general maps of the world, objects are placed nearer or more remote, and appear differently, according to the point wherein the eye is ſuppoſed to be placed; ſo the form of our ſyſtematical tree will vary, according to the point from which we view the world of ſcience. We may therefore figure to ourſelves as many different ſyſtems of knowledge, as there are different maps formed by different projections; and each ſyſtem may have ſome particular advantages over the reſt. Every man, perhaps, would place his own favourite ſcience in the centre of all the ſciences; as the men of the earlieſt ages, fancying the whole univerſe was made for them, placed themſelves in the middle of it.

We have choſen the diviſion recommended by the great lord Bacon. But we are too ſenſible how arbitrary all diviſions of the arts and ſciences muſt ever be, to imagine ours the beſt and only ſyſtem: we ſhall reſt ſatisfied if the intelligent favour it with their approbation.

The objects of our minds are either ſpiritual or material; and we are employed about them by means of direct or reflex ideas. Our ſtock of direct knowledge conſiſts of a merely paſſive, or mechanical, collection of things treaſured up in the memory.

Reflection, as we obſerved above, is of two kinds; and either reaſons upon or contemplates the objects of our direct ideas. The mind therefore operates in three different methods on the ſubject of its thoughts; viz. either by memory, reaſoning, or imagination.

By imagination we do not mean the faculty of recollecting ſenſible objects; this is no more than memory; which were it not for the uſe of ſigns, muſt be in continual exerciſe; but we uſe the word in a higher and more explicit ſenſe, for that faculty in us which creates objects by imitation.

Theſe three faculties form the three general diviſions of our ſyſtem, and the three general objects of human knowlege, viz. Hiſtory, which relates to memory; Philoſophy, which is the produce of reaſoning; and the Polite Arts, which ſpring from imagination.

The general diſtribution of ſubjects into ſpiritual and material, forms the ſubdiviſion of the three general branches of our knowlege. Hiſtory and philoſophy equally belong to both; while imagination operates wholly on material objects. At the head of ſpiritual beings ſtands God; who holds the firſt place by his nature, and the neceſſity we have of knowing him. Next to this Supreme Being, come created ſpirits; whoſe exiſtence we are taught by revelation. In the next place comes man; compoſed of two principles, body and ſoul; his ſoul participating of a ſpiritual nature, and his body of the material world. Laſtly, comes this immenſe univerſe, which we call the corporeal world, or nature.

Hiſtory, as it relates to the Supreme Being, includes revelation and tradition; and is accordingly divided into ſacred and profane. The *hiſtory of Man* hath human actions, and human knowlege, for its object; accordingly it is either civil or literary; and treats of powerful nations, and great geniuſſes; potentates and men of letters, conquerors and philoſophers. Laſtly, the *hiſtory of Nature* is the hiſtory of the numerous productions of nature: but among the reſt, a principal branch is the *hiſtory of Arts*, or the different purpoſes to which men have applied the productions of nature, either with regard to utility or curioſity.

With regard to the reaſoning faculties of man, they have both ſpiritual and material beings for their object; becauſe they have certain general properties, ſuch as exiſtence, poſſibility, and duration. The conſideration of theſe properties immediately forms Ontology, or that branch of philoſophy from which all the reſt borrow ſome part of their principles; becauſe it includes the ſcience of Being in general, or metaphyſics at large. From general ontology we deſcend to all the different particular beings; and the diviſions afforded by this ſcience of particular beings, form themſelves upon the ſame plan with the diviſion of Hiſtory.

Our knowlege of God, which paſſes under the name of Theology, divides itſelf into two branches; natural and revealed. Natural Theology, or the knowlege we have of God by reaſon alone, is very confined; but Revealed Theology derives a more perfect knowlege of him from ſcripture. Man alſo owes his knowlege of created beings to revelation.

A principal part of human knowlege is the knowlege of our ſouls; conſiſting in the ſpeculative knowlege of the ſoul itſelf, and of its operations. The ſpeculative knowlege of the ſoul participates both of natural and revealed theology; and is a branch of metaphyſics called Pneumatology. The ſpeculative knowlege of the ſoul's operations is ſubdivided into two branches; as its object is either the diſcovery of truth, or the practice of virtue. The diſcovery of truth, which is the end of Logic, conſtitutes the art of conveying truths to others: and hence the uſe we make of Logic is, in part, for our own ſakes, and, in part, for the ſakes of others. The rules of morality do not principally regard man in a ſolitary ſtate, but ſuppoſe him neceſſarily linked in ſociety.

The knowlege of nature is the knowlege of bodies, and their general properties, ſuch as impenetrability, mobility, and extenſion, which are firſt to be ſtudied in natural philoſophy. Theſe general properties being conſidered abſtractedly, open an immenſe field for ſpeculation; and when conſidered materially, they become the object of menſuration. Pure ſpeculation belongs to general phyſics, or the metaphyſics of body; and menſuration is the object of mathematics, the diviſion and application whereof are almoſt infinite.

Theſe two ſciences lead to particular phyſics, or Natural Philoſophy, which conſiders bodies as they are in themſelves; and has individuals for its object. Among theſe the human body is that whoſe properties we are principally concerned to know; and next after this come ſuch as are neceſſary to our preſervation: whence proceed Anatomy, Agriculture, Medicine, and their different branches. In ſhort, all the natural bodies ſubject to our examination, furniſh the other numerous branches of natural philoſophy.

Painting, Sculpture, Architecture, Poetry, and Muſic, with their ſubdiviſions, form the third general diviſion, which refers to the imagination; and are all comprehended under the title of Polite Arts. They might alſo be included under the general name of Painting; becauſe all the polite arts are reducible to painting, and differs only in regard to the means they employ. Or indeed they might all be referred to Poetry; taken in its natural ſignification, for invention or creation.

Such are the principal parts of our ſyſtematical plan of the Arts and Sciences; a fuller idea of which may be formed from what we call *A Syſtematical View of Human Knowledge*, added to this diſcourſe, and which the reader will do well to conſider with attention.

Before we conclude this Preface, it may be expected that we ſhould ſay ſomething of the ſeveral books of this kind already extant; ſome of which have been well received by the Public; but we hope the reputation of this work will be founded on its utility, and not on the ruins of others. We ingenuouſly confeſs, we have conſulted them all, and profited by them all; and ſhall therefore leave them in the quiet poſſeſſion of the reputation they have acquired. It is enough for us to declare, that we have uſed our utmoſt endeavours to render this work more uſeful than any that has preceded it; if we have ſucceeded in this attempt, we are ſatisfied, and the Public will reap the advantage of our labours.

THE COMPLETE

DICTIONARY

OF

ARTS and SCIENCES.

A, The character of the firſt letter of the alphabet in Latin, Engliſh, French, and moſt of the preſent languages of Europe. The firſt character in the Hebrew alphabet is called *aleph*, in the Greek *alpha*, in the Arabic *eleph*, and in the Syriac *oleph*.

A has deſervedly the firſt place in the alphabet on account of its ſimplicity, very little more being neceſſary to its pronunciation than opening the mouth. As a vowel it has in Engliſh a threefold ſound: ſhort, as in *bat*, *bat*, *&c.* like the Hebrew *pathahh:* long, as in *dâte*, *ſâte*, *&c.* and obſcure, as in *call*, *fall*, *&c.* where we hear the ſame ſound as in *olive*, *hollow*, *&c.* except its being long in the former, conformable to the Hebrew *kametz*, and ſhort in the latter, agreeable to *chateph kametz*.

A, among the ancients was a numeral letter, and ſignified 500; and when a daſh was added on the top, Ā, 5000.

A, in the Julian calendar, is the firſt of the dominical letters. It was alſo of uſe in the Roman comitia, or aſſemblies, for making laws, when the people had two tables given them: on the one were the two letters U. R. *uti rogas*, implying their aſſent; becauſe a motion for a new law was called *rogatio:* on the other the letter A, *antiquo*, or *antiquam volo*, to ſignify their diſſent. In capital caſes alſo they had two tables covered with wax, on one of which was the letter A, for *abſolvo*; and on the other C, for *condemno:* whence the former is called by Cicero *ſalutaris*, and the latter *triſtis*.

A, on ancient inſcriptions found on monuments and coins, has various ſignifications, as *Aguſtus*, *Ager*, *Aint*; and ſometimes its meaning can only be known by the reſt of the inſcription. Iſidorus obſerves, that the letter *a*, after the word *miles*, ſignifies that the ſoldier was a young man.

A is alſo an abbreviation, and often found in modern writers; as A. D. for *anno domini*, A. M. *artium magiſter*, maſter of arts, &c. Among logicians it is uſed to denote an univerſal affirmative propoſition.

A. A. A. among chemiſts, ſignifies an amalgama, or the operation of amalgamation.

A, *ā*, or *ā ā*, is uſed by phyſicians as an abbreviation of *ana*, and ſignifies an equal quantity of the ingredients that immediately precede it in the preſcription.

AABAM, a term uſed by ſome alchemiſts to ſignify lead.

AAM, a meaſure of capacity for liquids uſed at Amſterdam, containing about ſixty-three pounds, averdupois weight.

AB, the eleventh month of the civil year of the Hebrews, and the fifth of their eccleſiaſtical year, which begins with the month Niſan. It anſwers to the moon of July; that is, to part of our month of the ſame name, and to the beginning of Auguſt; it conſiſts of thirty days. The Jews faſt on the firſt of this month, in memory of Aaron's death; and on the ninth, becauſe on that day both the temple of Solomon, and that erected after the captivity, were burnt; the former by the Chaldeans, and the latter by the Romans. The ſame day is alſo remarkable among that people for the publication of Adrian's edict, wherein they were forbid to continue in Judea, or even to look back when at a diſtance from Jeruſalem, in order to lament the deſolation of that city. The eighteenth of the ſame month is alſo a faſt among the Jews; becauſe the lamp in the ſanctuary was that night extinguiſhed, in the time of Ahaz.

AB, in the Syriac calendar, is the name of the laſt ſummer month. The firſt day of this month they called *Saum-Miriam*, the faſt of the virgin, becauſe the eaſtern chriſtians faſted from that day to the fifteenth, which was therefore called *Fathr-Miriam*, the ceſſation of the faſt of the virgin. *D'Herbelot Bib. Orient.*

The vulgar year of the eaſtern Arabians, Perſians, and Turks, being purely lunar, they are obliged, in their aſtronomical calculations, to deviate from the common method of computing time, and have recourſe to the ſolar year, borrowing the names of the months from the Syriac calendar, which they call Rumi, or Greek; becauſe it was formerly peculiar to the Greeks of Syria, whom chronologiſts term Syro-Macedonians.

ABACO, among ancient writers, ſignifies arithmetic: the Italians ſtill uſe it to imply that ſcience.

ABACOT, the name of an ancient cap of ſtate, worn by the kings of England: the ſuperior part of it formed a double crown.

ABACTORS, or ABACTORES, a name given to thoſe who drive away, or rather ſteal cattle by herds, or great numbers at once; and are therefore very properly diſtinguiſhed from *fures*, or thieves. *Cunningham's Law Dict.*

The word is derived from *abigo*, compounded of *ab*, from, or away; and *ago*, to drive.

ABACUS, among the ancients, was a kind of buffet, or cupboard.

It is derived from the Greek, αβαξ, a table.

ABACUS, in architecture, is the ſuperior member of the capital, to which it ſerves as a kind of crown. It was originally intended to repreſent a ſquare tile laid over a baſket, an accident which Vitruvius tells us gave occaſion to Callimachus, an ingenious ſtatuary of Athens, to invent the firſt regular order of architecture. See CAPITAL.

The abacus ſtill retains its original form in the Tuſcan, Doric, and Ionic orders; but in the Corinthian and Compoſite, its four ſides or faces are arched inwards, having ſome ornament, as a roſe, or other flower, in the middle.

ABACUS is alſo uſed by Scamozzi for a concave moulding on the capital of the Tuſcan pedeſtal. And Andrea Palladio calls the plinth above the echinus, or boultin in the Tuſcan and Doric orders, by the ſame name.

ABACUS, among the ancient mathematicians, ſignified a table covered with duſt, on which they drew their diagrams; the word in this ſenſe being derived from the Phœnician *abak*, duſt.

ABACUS *Pythagoricus*, the common multiplication table; ſo called from its being invented by Pythagoras.

ABADDON, a name given by St. John in the Revelations, to the king of Locuſts. It is derived from *abad*, to deſtroy.

ABADIR, a word compoſed of two Phœnician terms, ſignifying magnificent father, a title which the Carthaginians gave to gods of the firſt order. In mythology it is the name of a ſtone which Saturn ſwallowed, from a perſuaſion that it was his infant ſon Jupiter.

ABAFT, in the ſea language, ſignifies towards the ſtern. Thus, when any thing is ſaid to be abaft the mizzen-maſt, it implies that the object is between the mizzen-maſt and the ſtern.

ABAPTISTON, in ſurgery, ſignifies the perforating part of the trepan; becauſe it is prevented from ſinking ſuddenly into the ſkull and wounding the brain.

It is derived from α, priv. and βαπτω, to ſink under.

ABARTICULATION, in anatomy, a particular kind of articulation, called diarthroſis. See DIARTHROSIS.

ABAS, a weight uſed by the Perſian merchants in weighing pearls. It is one eighth leſs than the European caratt.

ABASED, *abaſſe*, in heraldry, is applied to the wings of eagles, &c. when the extremity points downwards to the point of the ſhield, or when the wings are ſhut; the natural way of bearing them being extended.

ABATAMENTUM, in law, is an entry into lands by interpoſition; that is, when a perſon dies ſeized, and another, who has no right, enters before the heir. *Cunningham's Law Dict.*

To ABATE, (from the French *abbatre*, to pull down, overthrow, demoliſh, batter down, or deſtroy) a term uſed by the writers of the common law, both in an active and neutral ſenſe; as to abate a caſtle, is to beat it down. To abate a writ is, by ſome exception, to defeat or overthrow it. A ſtranger abateth; that is, entereth upon a houſe or land void by the death of him that laſt poſſeſſed it, before the heir takes poſſeſſion, and ſo keepeth him out; wherefore, as he that putteth out him in poſſeſſion is ſaid to diſſeize; ſo he that ſteppeth in between the former poſſeſſor and his heir, is ſaid to abate. In the neuter ſignification thus: the writ of the demandant ſhall abate; that is, ſhall be diſabled, fruſtrated, or overthrown. The appeal abateth by covin; that is, the accuſation is defeated by deceit. *Cunningham's Law Dict.*

To ABATE, in the manege, implies the performing any downward motion properly. Thus a horſe is ſaid to abate or take down his curvets, when he puts both his hind legs to the ground at once, and obſerves the ſame exactneſs in all the times.

ABATEMENT, in heraldry, implies ſomething added to a coat of arms, in order to leſſen its true dignity, and point out ſome imperfection, or ſtain, in the character of the wearer.

ABATEMENT, in law. See To ABATE.

ABATOR, in law, is a perſon who enters a houſe or lands, void by the death of the laſt poſſeſſor, before the true heir.

ABB, in the woollen manufacture, implies the yarn of a weaver's warp.

ABBESS, the ſuperior of an abbey, or convent of nuns, over whom ſhe enjoys the ſame privileges as the abbots over their monks. Her ſex does not indeed allow an abbeſs to perform the ſpiritual functions annexed to the prieſthood; but there are inſtances of ſome abbeſſes who have the privilege of commiſſioning a prieſt to act for them.

ABBEY, a religious houſe, or place, where perſons retire from the world to ſpend their time in ſolitude and devotion.

The wonderful eſteem ſuch men formerly acquired, procured them very large privileges, exemptions, and riches, which they drew from the people by the invention of maſſes for the living and the dead, diſpenſations, jubilees, indulgencies, &c.

Theſe religious houſes were totally aboliſhed in England by Henry VIII. who, in the twenty-eighth year of his reign, appointed viſitors to inſpect the abbeys, and examine into the behaviour of the monks; who, being convicted of having ſpirited up rebellions againſt the government, and committing many other diſorders, and perceiving the time of their diſſolution drawing near, were prevailed upon to reſign their houſes to the king; by which means the abbey-lands became veſted in the king, which were afterwards granted to the people, under which grants they are enjoyed to this day. There were one hundred and ninety ſuch religious houſes diſſolved, whoſe yearly revenues amounted to near 2853000 l.

ABBOT, or ABBAT, the ſuperior of an abbey or convent of monks.

The word is derived from the Syriac, *abba*, father.

In the firſt ages of chriſtianity the abbots were men of great plainneſs and ſimplicity, contented with the government of their own monaſteries, which were erected in the moſt ſolitary parts, without pretending to any ſhare in eccleſiaſtical affairs. But being called from theſe obſcure retreats to oppoſe the hereſies which too ſoon appeared in the church, they became ambitious of power, and endeavoured to render themſelves independent of the biſhops. It was however ſome time before they could carry their point of independency; but, having ſucceeded in that attempt, they ſoon obtained the title of lord, together with other badges of epiſcopal authority, particularly the mitre. Hence aroſe new ſpecies of diſtinctions between the abbots; thoſe were termed mitred abbots, who were privileged to wear the mitre, and exerciſe epiſcopal authority within their reſpective precincts. Others were called croſiered abbots, from their bearing the croſier, or paſtoral ſtaff. Others were ſtiled œcumenical, or univerſal abbots, in imitation of the patriarch of Conſtantinople: while others were termed cardinal abbots, from their ſuperiority over all other abbots.

At preſent the principal diſtinctions obſerved between abbots, are thoſe of regular and commendatory. The former take the vow and wear the habit of the order; whereas the latter are ſeculars, though they are obliged by their bulls to take orders when of proper age.

Before the Reformation in England, there were elective and preſentative abbots: ſome who were mitred, and ſome who were not. Such as were mitred had epiſcopal authority within their limits, being exempted from the juriſdiction of the biſhop; while the others were ſubject to the dioceſan in all ſpiritual government. The mitred abbots were lords of parliament, and called abbots ſovereign, and abbots general, to diſtinguiſh them from the other abbots. And as there were lords abbots, ſo there were alſo lords priors, who had exempt juriſdiction, and were likewiſe lords of parliament. Some reckon twenty-ſix of theſe lords, abbots, and priors, that ſat in parliament. Sir Edward Coke ſays, that there were twenty-ſeven parliamentary abbots, and two priors. In the parliament 20 R. II. there were but twenty-five abbots, and two priors: but in the ſummons to parliament, *Anno* 4 Ed. III. more are named.

ABBREVIATURE, or Abbreviation, implies the ſubſtitution of a ſyllable, letter, or character, for a whole word.

The word is derived from *abbrevio*, to ſhorten.

ABBREVOIR, in maſonry, ſignifies certain indentures made in the joints or beds of ſtones, that the mortar or cement may, by filling theſe cavities, bind the work the firmer together.

ABBUTTALS, or Abuttals, (from the French *aboutir*, to border upon) the buttings and boundings of land, either to the eaſt, weſt, north, or ſouth, ſhewing on whatever lands, rivers, highways, or other places it abbuts.

Cambden ſays, that limits were diſtinguiſhed by hillocks raiſed on purpoſe, which were called botentines; whence we have the word butting. In a terrier, or deſcription of the ſite of land, the ſides on the breadth are properly adjacentes, lying or bordering, and the ends only in length are abuttantes, abutting or bounding: which, in old ſurveys, they ſometimes expreſſed by capitare, to head; whence abuttals are now called head-lands. *Cunningham's Law Dictionary.*

ABCEDARY, or Abcedarian, an epithet applied to compoſitions whoſe parts are diſpoſed in alphabetical order.

ABDEST, a Perſian word, properly ſignifying the water placed in a baſon for waſhing the hands; but is uſed to imply the legal purifications in uſe among the Mahometans, before they enter on their religious ceremonies.

ABDICATION, the action where a magiſtrate, or perſon in office, renounces and gives up the ſame, before the term of ſervice is expired.

This word is frequently confounded with reſignation, but differs from it in that abdication is done purely and ſimply; whereas reſignation is in favour of ſome third perſon. It is ſaid to be a renunciation, quitting and relinquiſhing, ſo as to have nothing further to do with a thing; or the doing of ſuch actions as are inconſiſtent with the holding of it. On king James's leaving the kingdom, and abdicating the government, the lords would have the word deſertion made uſe of; but the commons thought it was not comprehenſive enough; for that the king might then have liberty of returning. *Cunningham's Law Dict.*

ABDOMEN, in anatomy, that part of the human body intercepted between the thorax and the pelvis.

The word is Latin, and derived from *abdo*, to hide.

Anatomiſts have generally divided the body into three great cavities, which they call bellies: the head, or the upper belly; the thorax, or the middle belly; and the abdomen, or lower belly. The Arabians, and ſome writers in the barbarous ages, called the abdomen, or at leaſt the external part of it, mirach; and the peritonæum, ſiphac.

The abdomen, ſays the accurate Winſlow, begins immediately under the thorax, and terminates at the bottom of the pelvis of the oſſa innominata. Its circumference, or outer ſurface, is divided into regions, of which there are three anterior, viz. the epigaſtric, or ſuperior region; the umbilical, or middle region; and the hypogaſtric, or lower region. There is but one poſterior region, named regio lumbaris.

The epigaſtric region begins immediately under the appendix enſiformis, at a ſmall ſuperficial depreſſion, called the pit of the ſtomach, and in adult ſubjects ends above the navel, at a tranſverſe line, ſuppoſed to be drawn between the laſt falſe ribs on each ſide.

This region is ſubdivided into three parts, one middle, named epigaſtrium; and two lateral, termed hypochondria. The epigaſtrium takes in all that ſpace which lies between the falſe ribs of both ſides; and the hypochondria are the places covered by the falſe ribs.

The umbilical region begins in adults, above the navel, at the tranſverſe line already mentioned, and ends below the navel at another tranſverſe line, ſuppoſed to be drawn parallel to the former, between the two criſtæ of the oſſa ilium.

This region is likewiſe divided into three parts; one middle, which is properly the regio umbilicalis; and two lateral, called ilia, or the flanks, and they comprehend the ſpace between the falſe ribs and the upper part of the os ilium on each ſide.

The hypogaſtric region is extended downward from the inferior limit of the umbilical region, and is divided into three parts, one middle, called pubes; and two lateral, called inguina, or the groins.

The lumbar region is the poſterior part of the abdomen, and comprehends all that ſpace which reaches from the loweſt ribs on each ſide, and the laſt vertebra of the back, to the os ſacrum, and neighbouring parts of the oſſa ilium. The lateral parts of this region are termed the loins; but the middle part has no proper name in men.

Laſtly, the bottom of the abdomen, which anſwers to the pelvis of the ſkeleton, is terminated anteriorly by the clunes, or buttocks, and anus. The buttocks are ſeparated by a foſſa, which leads to the anus, and each buttock is terminated downward by a large fold, which diſtinguiſhes it from the reſt of the thigh.

This lumbar region takes in likewiſe the muſculus quadratus lumborum on each ſide, the lower portions of the ſacrolumbares of the longiſſimi and latiſſimi dorſi, the muſculus ſacer, &c.

The ſpace between the anus and the parts of generation is called perinæum, and is divided into equal lateral parts by a diſtinct line, which is longer in males than in females.

The cavity of the abdomen, formed by the parts already mentioned, (all which are covered by the ſkin and membrana adipoſa) is lined on the inſide by a particular membrane, called peritonæum. It is ſeparated from the cavity of the thorax by the diaphragm, and terminated below by the muſculi levatores ani.

This cavity contains the ſtomach, and the inteſtines, which are commonly divided into three ſmall, named duodenum, jejunum, and ilium; and three large, called cœcum, colon, and rectum. It contains likewiſe the meſentery, meſocolon, omentum, liver, gall-bladder, ſpleen, pancreas, glands of the meſentery, vaſa lactea, receptaculum chyli, kidneys, renal glands, ureters, bladder, and the internal parts of generation in both ſexes. *Winſlow's Anat.*

ABDUCTION, in logic, a particular form of reaſoning, called by the Greeks *απαγωγη*, wherein we infer from a certain or undeniable propoſition, the truth of ſomething ſuppoſed to be contained in that propoſition.— The following ſyllogiſm is of this kind:

> Whatever God has revealed is undoubtedly true:
> But God has revealed the myſtery of the Trinity:
> Therefore that myſtery is undoubtedly true.

The major of the above ſyllogiſm is certain; but it remains to be proved that the minor, or aſſumption, is contained in the major.

Abduction, in ſurgery, is that ſpecies of fracture, when a bone near the joint is divided tranſverſely in ſuch a manner, that the extremities of the fractured bone recede from each other.

ABDUCTOR is a name given by anatomiſts to the following muſcles:

Abductor *Minimi Digiti Manus*, or *Abductor Auricularis*, ariſes fleſhy from the thin protuberating part of the eighth bone of the wriſt; is inſerted by a pretty long and round tendon, on the inſide of the ſhort tendon of the above deſcribed muſcle, near the upper part of the firſt bone of the little finger. It ſerves not only to abduce the little finger from the reſt, but alſo to bend it a little.

Abductor *Indicis*, ariſes broad and fleſhy from the ſuperior part of the firſt bone of the thumb; is inſerted by a ſhort tendon into the upper part of the firſt bone of the fore-finger, laterally, next the thumb. Its uſe is to bring the index towards the thumb, by drawing it from the middle finger.

ABDUCTOR *Minimi Digiti Pedis*, ariſes fleſhy and tendinous from the ſemicircular edge of a cavity, on the outſide of the inferior protuberance of the os calcis; it has another tendinous beginning from the os cuboides, and a third from the upper part of the os metatarſi minimi digiti; is inſerted into the upper part of the firſt bone of the little-toe externally and laterally. Its uſe is to draw the little-toe outwards from that next to it.

ABDUCTOR *Oculi*, ariſes tendinous and fleſhy from the foramen lacerum, without the orbit; is inſerted by a thin tendon into the ſclerotis, where it reſpects the great canthus. Its uſe is to move the eye outwards, from the great to the little angle.

ABDUCTOR *Pollicis Manus*, or *Thenar*, ariſes by a broad tendinous and fleſhy beginning from the tranſverſe ligament of the carpus, and from one of its bones that articulates with the thumb; is inſerted tendinous into the ſecond joint of digitorum manus. Its uſe is to draw the thumb from the fingers.

ABDUCTOR *Pollicis Pedis*, ariſes fleſhy from the inſide of the lower protuberance of the os calcis laterally, and tendinous from a little tubercle in the ſame bone, near the os cymbiforme. It only adheres to the other bones on the inſide of the foot, filling up the hollowneſs in the os metatarſi pollicis; is inſerted into the internal os ſeſamoideum of the firſt bone of the great toe; its tendons being farther continued upon the ſame bone laterally. Its uſe is to pull the great-toe from the reſt.

ABDUCTOR *Femoris Primus*, ariſes by a ſtrong roundiſh tendon from the upper part of the os pubis next the pectinæus above the gracilis; which, turning into a compact fleſhy belly, it begins to be inſerted tendinous about the middle of the linea aſpera, being continued down upon the ſame five or ſix inches, ſending out a tendon which joins with that of the femoris quartus.

ABDUCTOR *Femoris Secundus*, ariſes from the os pubis, immediately under the gracilis, by a broad tendinous, but chiefly fleſhy beginning; and is inſerted into the linea aſpera, from a little below the leſſer trochanter, to the firſt inſertion of the laſt deſcribed muſcle.

ABDUCTOR *Femoris Tertius*, ariſes lower down than the former, from the outer edge of the os pubis and iſchium; and, running obliquely towards the trochanter minor, is inſerted near the glutæus maximus.

ABDUCTOR *Femoris Quartus*, ariſes from the protuberance of the iſchium, and the adjoining interior part of that bone, by a tendinous and fleſhy origination; is inſerted by a round and long tendon, into the upper and rough part of the inner and lower appendix of the os femoris, being affixed to that bone a little above the condyle; as alſo to ſome part of the linea aſpera.

The uſe of all theſe four muſcles is to adduce or move the thigh bone inwards, according to their different directions. *Douglaſs on the Muſcles.*

ABELIANS, a ſect of heretics that ſprung up during the reign of Arcadius, near Hippo in Africa. Their diſtinguiſhing tenet was to marry, and yet to live with their wives without having any carnal commerce with them.

ABERRATION *of the Stars*, a ſmall apparent motion of the fixed ſtars diſcovered by the late Dr. Bradley.

The word is Latin, and compounded of *ab*, from, and *erro*, to wander, becauſe the ſtars appear to wander from their true ſituation.

This noble diſcovery was made by accident in the year 1725, when Mr. Molyneux and Dr. Bradley began to obſerve the bright ſtar in the head of *Draco*, marked γ by Bayer, as it paſſed near the zenith, with an inſtrument made by Mr. Graham, in order to diſcover the parallax of the earth's annual orbit, and after repeated obſervations they found this ſtar, about the beginning of March 1726, to be 20″ more ſoutherly than at the time of the firſt obſervation. It now indeed ſeemed to have arrived at its utmoſt limit ſouthward; becauſe, in ſeveral trials made about this time, no ſenſible difference was obſerved in its ſituation. By the middle of April it appeared to be returning back again toward the north, and about the beginning of June it paſſed at the ſame diſtance from the zenith as it had done in December, when it was firſt obſerved; in September following it appeared 39″ more northerly than it was in March, juſt the contrary way to what it ought to appear by the annual parallax of the ſtars.

This unexpected phænomenon perplexed the obſervers very much; and Mr. Molyneux died before the true cauſe of it was diſcovered. After this, Dr. Bradley, with another inſtrument more exact and accurately adapted to this purpoſe, obſerved the ſame appearances not only in that but in many other ſtars: and, by the great regularity that appeared in a ſeries of obſervations made in all parts of the year, the doctor was fully ſatisfied with regard to the general laws of the phænomena; and therefore endeavoured to find out the cauſe of them. He was already convinced that the apparent motion of the ſtars was not owing to a nutation of the earth's axis. The next thing that offered itſelf, was an alteration in the direction of the plumb line, with which the inſtrument was conſtantly rectified; but this, upon trial, proved inſufficient. Then he had recourſe to what refraction might do, but here alſo nothing ſatisfactory occurred. At laſt, through a moſt amazing ſagacity, this acute aſtronomer conjectured, that all the phænomena, hitherto mentioned, proceeded from the progreſſive motion of light, and the earth's annual motion in its orbit: for he perceived, that if light was propagated in time, the apparent place of a fixed object would not be the ſame when the eye is at reſt, as when it is moving in any other direction, than that of the line paſſing through the eye and object; and that, when the eye is moving in different directions, the apparent place of the object would be different.

He conſidered this matter in the following manner: he imagined C A (plate I. *fig.* 1.) to be a ray of light, falling perpendicularly upon the line B D; then if the eye is at reſt at A, the object muſt appear in the direction A C, whether light be propagated in time, or in an inſtant. But if the eye is moving from B towards A, and light is propagated in time, with a velocity, that is, to the velocity of the eye, as C A to B A; then light moving from C to A, whilſt the eye moves from B to A, that particle of it, by which the object will be diſcerned when the eye in its motion comes to A, is at C, when the eye is at B. Joining the points B, C, he ſuppoſed the line C B, to be a tube (inclined to the line B D, in the angle D B C) of ſuch a diameter as to admit of but one particle of light; then it was eaſy to conceive that the particle of light at C (by which the object muſt be ſeen when the eye, as it moves along, arrives at A) would paſs through the tube B C, if it were inclined to B D in the angle D B C, and accompanied the eye in its motion from B to A; and that it could not come to the eye placed behind ſuch a tube, if it had any other inclination to the line B D. If, inſtead of ſuppoſing C D ſo ſmall a tube, we imagine it to be the axis of a larger; then, for the ſame reaſon, the particle of light at C cannot paſs through that axis, unleſs it be inclined to B D, in the angle C B D. In like manner, if the eye move the contrary way, from D towards A, with the ſame velocity; then the tube muſt be inclined in the angle B D C. Therefore, although the true or real place of an object is perpendicular to the line in which the eye is moving, yet the viſible place will not be ſo, ſince that muſt doubtleſs be in the direction of the tube; but the difference between the true and apparent place will be, *cæteris paribus*, greater or leſs, according to the different proportion between the velocity of light, and that of the eye. So that if we could ſuppoſe that light was propagated in an inſtant, then there would be no difference between the real and viſible place of an object, although the eye were in motion; for, in that caſe, A C being infinite with reſpect to A B, the angle A C B (the difference between the true and viſible place) vaniſhes. But if light be propagated in time, (which will be readily allowed by moſt of the philoſophers of this age), then it is evident from the foregoing conſiderations, that there will be always a difference between the real and viſible place of an object, unleſs the eye is moving either directly towards or from the object. And in all caſes the ſine of the difference between the real and viſible place of the object, will be to the ſine of the viſible inclination of the object, or the line in which the eye is moving, as the velocity of the eye, to the velocity of light. If light moved but 1000 times faſter than the eye, and an object (ſuppoſed to be at an infinite diſtance) was really

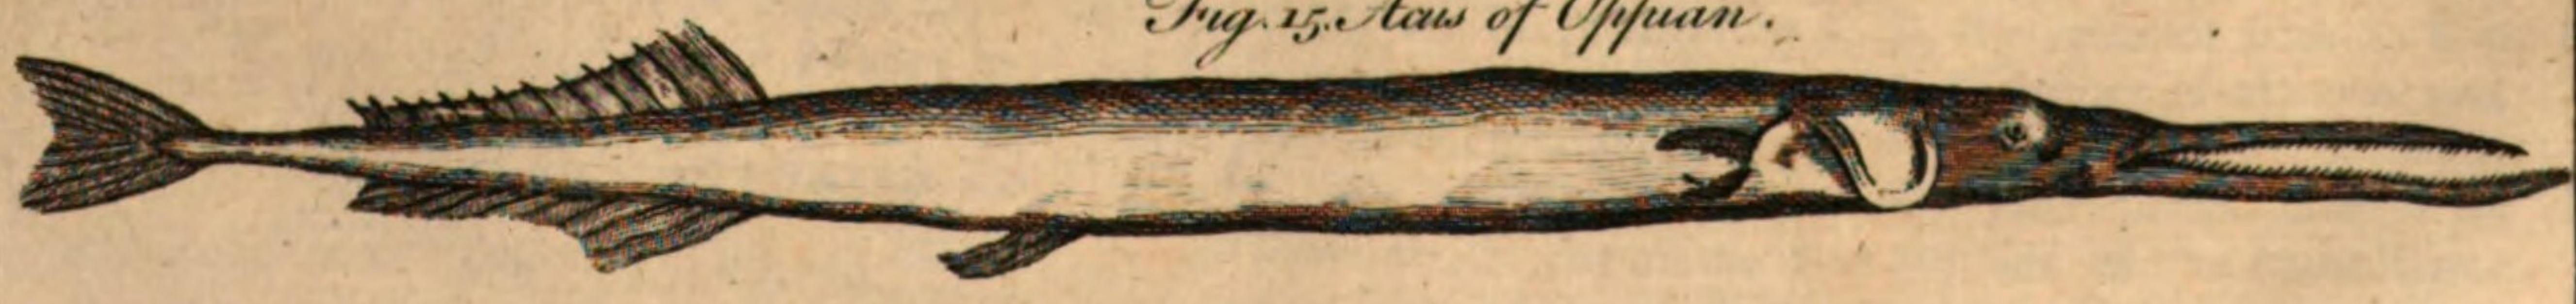

Fig. 15. Acus of Oppian.

placed perpendicularly over the plane in which the eye is moving, it follows from what has been ſaid, that ſuch object's apparent place will be always inclined to that plane, in an angle of 89°, 56′ ½; ſo that it will conſtantly appear 3′ ½ from its true place, and ſeem ſo much leſs inclined to the plane, that way towards which the eye tends; that is, if A C is to A B, or A D, as 1000 to 1, the angle A B C will be 89°, 56′ ½, and A C B = 3′ ½, and B C D = 2 A C B = 7′, if the direction of the eye's motion is at one time contrary to what is at another.

If the earth revolve round the ſun annually, and the velocity of light were to the velocity of the earth's motion in its orbit, (ſuppoſed circular as it nearly is), as 1000 to 1; then it is eaſy to conceive that a ſtar, really placed in the very pole of the ecliptic, would, to an eye carried along with the earth, ſeem to change its place continually, and, neglecting the ſmall difference on account of the earth's diurnal revolution on its axis, would ſeem to deſcribe a circle round that pole, every way diſtant therefrom 3′ ½: ſo that its longitude would be varied through all the points of the ecliptic, every year; but its latitude would always remain the ſame. Its right aſcenſion would alſo change, and its declination according to the different ſituation of the ſun in reſpect of the equinoctial points, and its apparent diſtance from the north pole of the equator, would be 7′ leſs at the autumnal than at the vernal equinox. The greateſt alteration of the place of a ſtar in the pole of the ecliptic (or which in effect amounts to the ſame, the proportion between the velocity of light and the earth's motion in its orbit) being known, it will not be difficult to find what would be the difference upon this account, between the true and apparent place of any other ſtar at any time; and, on the contrary, the difference between the true and apparent place being given, the proportion between the velocity of light and the earth's motion in its orbit may be found.

PROPOSITION.

Having given from experiment, the ratio of the velocity of light, to that of the earth in its orbit, and the true places of the ſun and ſtar, to find the apparent place of the ſtar from thence ariſing; the earth being here conſidered as moving in an orbit perfectly circular, from which its real orbit does not greatly differ.

Let A r Q A (plate I. *fig.* 2.) be the earth's orbit, conſidered as a circle; S the ſun in the center; r the earth moving about the ſame from A towards Q; re a line, which being produced ſhall paſs through the ecliptic place of the given ſtar A S parallel and gr perpendicular thereto: let ef be perpendicular to the plane of the ecliptic, ſo that rf being equal to S r or radius, re may be the coſine of the latitude of the given ſtar: this being premiſed, it is evident that the true place of the ſtar from the earth will be in the direction rf, and with reſpect to the ecliptic, in the line re; therefore the angle S re, (= Q S r) being the difference of longitudes of the ſun and ſtar, is given by the queſtion. Let rg, the ſine of the ſupplement of this angle, be denoted by b, its coſine S g by c, the ſign of the given latitude or fe by s; and the radius S r or fr by unity; and while a particle of light is moving along fr, let the earth be ſuppoſed to be carried in its orbit from r to p, over a diſtance ſignified by r, and pe; pf being drawn, make rn and mn perpendicular thereto: then, becauſe of the exceeding ſmallneſs of pr, it may be conſidered as a right line, and we ſhall have 1 (S r) : b (rg) :: r (pr) : rb (= pn); and 1 : r :: c : rc (= rn), by the ſimilarity of the triangles prn, S rg; whence as 1 (fp) to s (fe) ſo is rb, to rbs = (nm) the ſine of the angle nfm: but ſince the ſine of the tangent of a very ſmall arch differs inſenſibly from the arch itſelf, theſe values rc and rbs may be taken as the meaſures of the angles rfn, and nfm: hence we have, as the ſemiperiphery A r Q (= 3.14159, &c.) to 648000 (the ſeconds in 180 degrees) ſo is rc to $\frac{648000\,rc}{3.14159,\&c.}$ (the number of ſeconds in the angle rfn); and as 3.14159, &c. : 648000 :: rbs : $\frac{648000\,rsb}{3.14159,\&c.} = nfm$: therefore, as the earth moves from r to p, while a particle of light is deſcribing fr, it is manifeſt from what has preceded, that the ſtar will appear removed from the great circle paſſing through its true place, and the pole of the ecliptic by $\frac{648000\,rc}{3.14159,\&c.}$ ſeconds, and to have its latitude increaſed by $\frac{648000\,rsb}{3.14159,\&c.}$ ſeconds. Q. E. I.

Corol. I. Hence if C (plate I. *fig.* 3) be the true place of the ſtar, S C F its parallel of latitude, and about C, as a center, the ellipſe F P S T F, and circle F H S O F be deſcribed ſo, that F C may be = $\frac{648000}{3.14159,\&c.}$ and T C, the ſemiconjugate axis, in proportion thereto as s to 1; and if the angles S C H be taken equal to the difference of longitudes of the ſun and ſtar, then in the point P, where the elliptical periphery is interſected by the right line H Q, falling perpendicularly on F S, the ſtar will appear to be poſited. For as 1 (*radius*) : b (ſine of Q C H) :: C H : $b \times$ C H = H Q; but by the relation of the two curves C H : C T :: $b \times$ C H (= H Q) : P Q; that is, by conſtruction, $1 : s :: \frac{648000\,r}{3.14159,\&c.} \times b : \frac{648000\,rsb}{3.14159,\&c.}$ = P Q; again, as 1 (*radius*) : c (the coſine of Q C H) :: $\frac{648000\,r}{3.14159,\&c.}$ (= C H) : $\frac{648000\,rc}{3.14159,\&c.}$ = C Q; which expreſſions are the very ſame with thoſe abovementioned.

Corol. II. Therefore it follows, that while the ſun appears to purſue his courſe through the ecliptic, the ſtar will be ſeen as moving from F towards L and S, and ſo on till it hath deſcribed the whole elliptic periphery F L S T F, that its latitude will be the leaſt at T, and its apparent longitude the greateſt poſſible, when the angle S C H, ſhewing the diſtance of the ſun and ſtar in the ecliptic, is equal to two right ones. It alſo follows, that the greater axes of the ellipſes, which all ſtars appear to deſcribe, are equal, having been finally determined by Dr. Bradley, from a multitude of accurate obſervations, to amount to 40″ of a great circle. The term 20″, which frequently occurs in the following practical rules, is put for one half thereof; as repreſenting the radius of the ſmall circle, which a ſtar, ſuppoſed placed in either of the poles of the ecliptic, would appear annually to deſcribe about ſuch pole as a center. It follows moreover, that the greateſt aberrations, or *maxima*, in longitude, will be as the coſines of the latitude inverſely; and the *maxima* in latitude, as the ſines of the ſame latitudes directly.

Corol. III. Hence may alſo be found, the ſtars apparent right aſcenſion and declination, ; for let E C P be the parallel of the ſtar's declination, P the apparent place of the ſtar, when in that parallel, make C A perpendicular to C H, A B D to S F, and B E to P C, and let H K, or the angle H C K, be any diſtance gone over by the earth in the ecliptic, while the ſtar by its apparent motion moves through the correſponding diſtance P L. Let K m n G be parallel to H C, and L r v to P C: then foraſmuch as K L is parallel to H P, the triangles G K L, C H P, muſt be equiangular; and therefore G L : C P :: K L : H P; but K L is to H P, as L I to Q P, by the property of the curve, whence it will be G L : C P :: L I : Q P; wherefore the ſides G L, I L, C P, Q P, about the equal angles G L I, C P Q, being proportional, the triangles G L I, C P Q muſt be ſimilar, and therefore the angle G I L a right one; and conſequently the right line S F, the locus of the point G. Therefore, as the angles n, m, r, v, are all given, or continue invariable; let the angle S C K, or the ecliptic diſtance of the ſun and ſtar, be what it will, the ratio of C m to C G, will always be given; but the ratio of C G to C r is given: therefore the ratio of C m to C r is likewiſe given: hence becauſe rv is parallel to C E, the ratio of C m to E v will be given. But E v is the difference of the true and apparent declinations; and C m is as the ſine of the angle H C K; whence it is manifeſt, that the aberration of declination, at any time, is as the ſine of the ſun's elongation from either of the true points wherein he is, when the true and apparent declinations are the ſame; and therefore C m will be to E v, or A C to E B, the greateſt aberration, as Q H to F h; that is, as the ſine of H C F to the ſine of P C Q; but P C Q being equal to the while the Sabbatical and Jubilean years began at the autumnal equinox; but the months were counted from the vernal equinox only. Hence the month *Abib*, or *Niſan*, which before was the ſeventh month, was by God's particular command to Moſes, reckoned the firſt month of the year; and that which had been called the firſt, was termed the ſeventh month. Hence the Chaldee paraphraſt on the 1 Kings, chap. viii. 3. ſays, the month Ethanim, which was called by the ancients the firſt, is now called the ſeventh.

ABIES, in botany, the fir-tree. See Fir-tree.

ABIGEUS, in law, the ſame with Abactor, or one who ſteals whole herds of cattle.

ABINTESTATE, a word uſed in the civil law, and applied to a perſon who inherits from a perſon that died inteſtate, or without a will.

ABISHERING, in old law books, ſignifies a freedom or liberty from amercements. It is often found in charters or grants, where it implies that the perſon to whom ſuch grant is made, is intitled to the forfeitures and amercements of all others within his fee for tranſgreſſions; and at the ſame time, is himſelf free from the controul of any within that diſtrict.

ABJURATION, the renouncing or denying a thing or oath. Thus the abjuration of hereſy is the ſolemn renunciation of ſome doctrine as wicked and falſe.

The word is Latin, and compounded of *ab*, againſt, and *juro*, to ſwear.

Abjuration, in law, implies a ſworn baniſhment, as an oath taken to forſake the realm for ever.

ABLACTATION, in phyſic, implies the weaning of a child. See the article Weaning.

The word is Latin, and compounded of *ab*, from, and *lac*, milk.

Ablactation, in gardening, is a ſpecies of grafting, now called grafting by approach. See Grafting.

ABLAQUEATION, in gardening, is the act of taking the earth from the roots of trees, in order to expoſe thoſe parts to the immediate influence of the ſun, air, and rain. Our gardeners call it *baring of trees*.

The word is formed from the Latin *ab*, and *lacus*, a ditch.

ABLATIVE, in grammar, the ſixth caſe of Latin nouns.

The word is formed from *auferro*, to take away.

This caſe is peculiar to the Latin language, and is oppoſed to the dative, becauſe the former expreſſes the action of taking away, and the latter of giving.

ABLECTI, a ſelect body of ſoldiers among the Romans, choſen from thoſe termed *extraordinarii*.

ABLEGMINA, among the ancient Romans, ſignified thoſe parts of the intrails of victims, which were ſprinkled with flour and burnt upon the altar.

ABLUENTS, in medicine, are the ſame with diluents, or ſuch as carry off acrimonious and ſtimulating ſalts from the ſtomach and bowels.

ABLUTION, in a religious ſenſe, ſignifies the act of waſhing or purifying the body with water, a ceremony in uſe among the ancient Romans, and ſtill practiſed with the utmoſt ſtrictneſs by the Mahometans. It is uſed in the church of Rome to ſignify the little wine and water which the communicants formerly drank after the hoſt.

Ablution, in pharmacy, is the waſhing or purifying a body by frequent affuſions of warm water, or any proper fluid. See Edulcoration.

ABOLITION, the act of deſtroying or reducing a thing to nothing. In law, it ſignifies the eraſing any particular from the memory, ſo as no farther proſecution may enſue.

ABOMASUS, or Abomasum, the name of the fourth ſtomach of a beaſt that ruminates or chews the cud. The firſt is called venter, the ſecond reticulum, the third omaſus, and the fourth abomaſus. The abomaſus is that commonly called the maw, where the chyle is formed, and from whence the food deſcends to the inteſtines.

ABOMINATION a term uſed in ſcripture with regard to the Hebrews, who being ſhepherds, are ſaid to have been an abomination to the Egyptians; becauſe they ſacrificed the ſacred animals of that people, as oxen, goats, ſheep, &c. which the Egyptians eſteemed as abominations, or things unlawful. The term is alſo applied in the ſacred writings to idolatry and idols, becauſe the worſhip of idols is in itſelf an abominable thing; and at the ſame time the ceremonies obſerved by idolaters were always attended with licentiouſneſs, and other odious and abominable actions. The *abomination of deſolation*, foretold by the prophet Daniel, is ſuppoſed to imply the ſtatue of Jupiter Olympius, which Antiochus Epiphanes cauſed to be placed in the temple of Jeruſalem. And the *abomination of deſolation*, mentioned by the Evangeliſts, ſignifies the enſigns of the Romans, during the laſt ſiege of Jeruſalem by Titus, on which the figures of their gods and emperors were embroidered, and placed upon the temple after it was taken.

ABORIGINES, a name applied to the original or firſt inhabitants of any country; but is particularly uſed to ſignify the ancient inhabitants of Latium, a part of Italy now called Romania, or Campagna di Roma.

ABORTION, in phyſic, is a ſpaſmodico-convulſive motion of the uterus, by which an immature and dead fœtus is violently excluded, and generally preceded with an enormous flux of blood.

An abortion generally happens between the ſecond and third month; ſometimes between the third and fourth; and more rarely between the fifth and ſixth month of pregnancy, about the time that the menſes were wont to flow. There are not wanting inſtances of the placenta being violently ſeparated from the womb about the ſeventh month, with a large flux of blood, whereupon the infant's, and unleſs nature be ſtrong enough to expel it, the mother's life is greatly in danger.

The ſigns of an approaching abortion are not unlike thoſe of a natural birth. In both caſes there is a ſhivering and coldneſs; a preſſing pain in the loins, extending itſelf to the pelvis; afterwards it proceeds to the os ſacrum, coxendix, and groin, with a ſtronger pulſation of the arteries; the os uteri is moiſt and relaxed, and a water like the waſhing of fleſh breaks forth. Particularly in an abortion there is pure blood, which clots in a pretty large quantity, with great weakneſs; ſometimes fainting, and on the third day the fœtus is expelled. There often precedes a ſudden rigour and horror, with laſſitude, inappetence, nauſea, palpitation of the heart, a pain in the loins, a heavy pain about the pubes, and the genital parts are cold. The greater the fœtus is the more ſharp are the ſpaſms, and the pains and ſymptoms as well as the danger are the greater. *Hoffman*.

The forerunners of an abortion are a pain in the loins, or rather in the bottom of the uterus; a dull heavy pain in the inward parts of the thighs; ſlight ſhivering between the fleſh and the ſkin; the belly, from being eminent and pointed about the navel, becomes flat and depreſſed; the infant is motionleſs; the breaſts ſubſide and become flaccid; a ſmall flux of blood or ſerum oozes from the uterus, and is ſucceeded by an efflux of the waters, flooding, &c. with acute colic pains in the uterus from its convulſive contraction; pain about the os pubis, and os ſacrum, from the falling down of the fœtus to the orifice of the uterus; a deſire of going to ſtool; then follow weakneſs, convulſive contractions by conſent of parts, a ſyncope, and other ſymptoms. *Aſtruc*.

Women that abound with blood often have their menſes in the ſecond and third month of pregnancy, without any bad ſymptoms. In this caſe the blood, which proceeds from the veſſels of the vagina, yields relief; I have known it happen in the middle of the pregnancy, without detriment to the fœtus. The moſt violent drugs will not procure abortion in ſome women. I have known ſome afflicted with acute fevers, the ſmall-pox, meaſles, diarrhœas, and even dyſenteries, and yet the fœtus has remained ſafe and ſound. Others have travelled night and day in mountainous countries, or have been greatly fatigued with exceſſive dancing without any harm. Nor do ſudden fires, or other terrifying accidents, cauſe many abortions, if any at all.

However, women full of blood, inactive, ſoft, fat, of a more ſubtile habit of body, who live high, are weakly, of greater ſenſibility, hyſteric, inordinate in their menſes, who have miſcarried, or whoſe mothers were prone thereto, are more liable to abortion than robuſt, ſtrong, fleſhy women of the loweſt claſs, who are not fat but inured to labour, and not apt to be terrified on every ſlight occaſion. *Hoffman.*

Abortion is cauſed by the ſeparation of the placenta from the uterus, by the extravaſation of ſome fluid; by a corrugation of the placenta, by violent ſhocks; ſuch as violent fevers, ſmall-pox, lues venerea, vomiting, teneſmus, convulſions, &c. from ſtrong cathartics, emmenagogues, hæmorrhages, ſudden paſſions, frights, ſorrow, violent motions, as leaping, dancing, riding, jolting in carriages, raiſing great weights, ſtrokes on the belly, falls and fluxes of all kinds. *Aſtruc.*

To prevent abortion, bleeding is uſeful and neceſſary about the end of the third month of pregnancy, more or leſs according to the conſtitution of the patient. When there are gentle pains in the loins, deſcending to the hips and os ſacrum, then bleeding in the upper parts is abſolutely neceſſary. The body, in the firſt month eſpecially, ſhould be kept open with manna, rhubarb, or the like.

Abortion is alſo uſed, though ſomewhat abuſively, to ſignify a fœtus, which, dying in the womb, continues there beyond the time of geſtation.

ABORTIVE is, in general, applied to whatever comes before its legitimate time, or to a deſign which miſcarries.

ABRA, a ſilver coin ſtruck in Poland, and worth about one ſhilling Engliſh. It is current in ſeveral parts of Germany, Conſtantinople, Aſtracan, Smyrna, and Grand Cairo.

ABRACADABRA, a magical or cabaliſtical word, recommended by Serenus Samonicus as a cure for agues. But we live in an age too much enlightened to render it neceſſary for us to ſhew that the virtues attributed to this charm are merely chimerical.

The word, according to Selden, is formed from *Abracax*, the name of a Syrian idol.

ABRAHAM's **Balm**, in botany, a name ſometimes given to hemp. See **Hemp.**

ABRAHAMITES, an order of monks, who in the ninth century were exterminated by Theophilus for the worſhip of images. It is alſo the name of a ſect of heretics, who renewed the errors of the the Paulicians.

ABRASION, in phyſic, implies a ſuperficial exulceration of the membranous parts, attended with the loſs of ſubſtance. Thus there is ſaid to be an abraſion of the inteſtines, when the internal membrane is ulcerated, and minute pieces of it are voided with the excrement. This is too often the effect of draſtic purges, and can only be relieved by emollients capable of blunting the ſpiculæ of ſuch medicines.

ABRAXAS, or **Abrasax**, a myſtical name uſed in the ancient philoſophy and theology of certain heretics, particularly the Baſilidians.

Some of the modern authors are of opinion that Baſilides called the Supreme Being by the name *Abraxas*; but St. Jerome tells us, that *Abraxas* was properly the name of Mithras, or the ſun; and Ireneus adds, that the Baſilidians gave no name whatſoever to the Supreme Being. "The father of all things, ſay they, is ineffable, and hath no name."

M. Baſnage, in his hiſtory of the Jews, obſerves, that the word *abraxas* owes its origin to the Egyptians; for we meet with a great number of amulets, on which is an Harpocrates ſitting on the lotus, with the flagellum in his hand, and the word *abraſax*. In the ſeventeenth century two taliſmans were found, on one of which was the word ΑΒΡΑϹΑΣ in Greek capitals; and on the other, ſtill preſerved in the cabinet of St. Genevieve, the following inſcription: ΑΒΡΑϹΑΞ. ΑΔΩΝΑΙ. ΔΑΙΜΟΝΩΝ. ΔΕΞΙΑΙ. ΔΥΝΑΜΕΙϹ. ΦΥΛΑΞΑΤΕ. ΟΥΛΒΙΑΝ. ΠΑΥΛΕΙΝΑΝ. ΑΠΟ. ΠΑΝΤΟϹ. ΚΑΚΟΪ. ΔΑΙΜΟΝΟϹ. That is, "Abracas Adonai, lord of demons, good "powers, preſerve Ulpius Paulinus from every evil "demon."

M. de Bauſobre has been fortunate enough to diſcover the true meaning of the word *abraxas*. "I believe, ſays "that ingenious writer, that *abraxas*, or *abraſax*, is compounded of two Greek words; the firſt is *αβρος*, which "has divers ſignifications, and among others, that of "*beautiful* and *magnificent*, and is an epithet or attribute "of the god *Iao*, as we find in the oracle of Apollo, "related by Macrobius, Saturnal. l. 1. 17.

> Κειματι μεν τ᾽ Αιδην, Δαι δε ειαρος αρχομενοιο,
> Ηελιον δε ιερειν μεταπωρα δ᾽ αβρον Ιαω.

That is, *Pluto preſides over the winter, Jupiter over the ſpring, the Sun over the ſummer, and the beautiful Iao over the autumn.* "It is commonly tranſlated *mollis Iao*, which "does not ſignify a ſoft, weak divinity, but a divinity "which furniſhes mankind with all the delicacies of life, "and preſides over autumn, which is the ſeaſon of wine "and fruits—Αβρος likewiſe ſignifies *beautiful, majeſtic, ſuperb*, whence the *αβραβαινειν*, of Euripides, to expreſs a ſuperb majeſtic gait. In the verſes cited above "Iao is Bacchus; and Bacchus is the ſun, as Macrobius "has endeavoured to ſhew: but, however that be, *αβρος* "is an epithet frequently given to the ſun.—The other "Greek word, of which *abraſax* is compoſed, is either "ΣΑΩ, which is often uſed by Homer, and ſignifies *to ſave*, or *to cure*: or ΣΑ, which implies *ſafety* or *health.* "Thus *abraſax* literally ſignifies the beautiful, the magnificent Saviour, he who cures diſeaſes and preſerves "us from them." *Hiſt. du Manichieſm, tom.* ii. *p.* 55.

ABRIDGEMENT, an epitome, ſummary, or ſubſtance of a diſcourſe, in which only the eſſential part of what is elſewhere treated of more at large is preſerved.

Abridgements are very convenient for ſuch as have neither leiſure to conſult the originals, ability to purchaſe them, or talents to underſtand what a correct and ſkilful compiler lays before them. But then they ſhould convey a thorough knowledge of the matter treated of, and become what a miniature painting is to a picture drawn at full length. We may give a general idea of an extenſive hiſtory, or other matter; but we ſhould not enter upon a detail which we cannot explain, and of which we can only convey a confuſed notion, without yielding inſtruction, or reviving any ideas the reader had before acquired. Thus, for inſtance, if we ſay that Rome was at firſt governed by kings, whoſe authority continued during life, afterwards by two conſuls annually choſen, though that cuſtom was interrupted for ſome years; that then they elected the decemviri, and inveſted them with the ſupreme authority, but ſoon after reſumed their old cuſtom of electing conſuls; till at length Julius Cæſar, and after him Auguſtus, ſeized the ſupreme authority, from which period they and their ſucceſſors were ſtiled emperors; this account ſeems to convey a clear idea, and to be eaſily underſtood; but there are too many abridgements that give us only a confuſed notion, without the leaſt degree of certainty.

Abridgement is alſo uſed to expreſs a ſhort or contracted method of writing by uſing the initial letter, or ſome contraction of the word for the word itſelf; as *hon.* for honourable, A. D. for *anno domini*, *&c.* This cuſtom was greatly in uſe among the ancients, where we often meet with D. O. M. *deo optimo maximo*, A. R. S. H. *anno reparatæ ſalutis humanæ*, *&c.* In Latin epiſtles we commonly find S. P. D. *ſalutem plurimam dicit*; and in inſcriptions, D. V. C. *dicat vovet conſecrat.* Sertorius Urſatus has publiſhed a collection of explanations *de Notis Romanorum.*

Abridgement, in law, ſignifies the making a declaration or count ſhorter, by leaving out ſome of the ſubſtance. A man is ſaid to abridge his plaint in aſſize, and a woman her demand in an action of dower, where any land is put into the plaint or demand, which is not in the tenure of the defendant; for if the defendant; pleads non-tenure, joint tenancy, &c. in abatement of the writ, the plaintiff may leave out thoſe lands, and pray that the tenant may anſwer to the reſt. The reaſon for this abridgement of plaint is, becauſe the certainty is not ſet down in ſuch writs, but they run in general; and though the demandant hath abridged his plan, in part, yet the writ will hold good for the remainder.

Abridgement, in mathematics, is particularly uſed for the reducing a compound equation to a more ſimple form of expreſſion, by repreſenting all the known quantities of the ſame term by one ſingle letter.

Thus in the equation $x^3-ax^2+abx-abc=o$, by putting $-a=n$, $ab=p$, $abc=q$, inſtead of the equation firſt propoſed, we have this more ſimple but equivalent one $x^3-nx^2+px-q=o$.

ABROGATION, the aboliſhing or totally repealing a law.

ABROTANUM *Mas*, in the materia medica, a plant well known in England by the name of ſouthernwood. It has ſmall woody branches; numerous greyiſh green leaves divided into ſlender ſegments; and ſmall, yellow, naked, diſcous flowers, hanging downwards, in cluſters, along the ſides of the ſtalks and branches.

This plant is a native of open mountainous places in the warmer climates. With us it is raiſed in gardens from ſlips or cuttings, ſeldom producing ſeeds, and not often flowers. The leaves fall off in the winter; the roots and ſtalks are perennial.

The leaves and tops of ſouthernwood have a ſtrong ſmell, to many people agreeable, and a nauſeous penetrating bitteriſh taſte; they loſe a little by drying, both of their taſte and ſmell. The flowers are ſomewhat weaker than the leaves. The cortical part of the younger roots has a light, not ungrateful bitterneſs, with little or nothing of the peculiar flavour of the herb.

Infuſions of the leaves made in water are of a browniſh hue, in taſte and ſmell not unpleaſant; decoctions are darker coloured and very nauſeous. In diſtillation with water, there ariſes an eſſential oil of a bright yellow colour, in ſmell exactly reſembling the plant. This oil diſtils ſlowly, and towards the end of the proceſs proves very foul; rectified or diſtilled a ſecond time with freſh water, it leaves behind a conſiderable quantity of inodorous and almoſt inſipid reſinous matter. From ſixteen pounds of the freſh leaves and tops were obtained ſcarcely three drams of oil, which left in rectification above half a dram of reſin.

Tinctures of the leaves, made in rectified ſpirit, are of a deep green colour, and taſte ſtrongly of the ſouthernwood; the ſmell is covered by the ſpirit. The ſpirit, diſtilled off from the filtered tincture, has very little of the flavour of the herb; the remaining extract retains a conſiderable ſhare of its ſmell, and reſembles it more perfectly in taſte than an extract made by water, though it is much leſs ungrateful than either that extract or the herb in ſubſtance. Rectified ſpirit appears to diſſolve the aromatic part more eaſily, and the nauſeous part more difficultly than watery menſtrua.

This bitteriſh pungent plant has been employed as a moderately ſtimulating deobſtruent, in different cachectic diſorders, as an anthelmintic, and as poſſeſſing ſome degree of an anodyne or antiſpaſmodic virtue, depending on the oil or odorous matter. In the preſent practice it is ſcarcely otherwiſe made uſe of than for external purpoſes, as an ingredient in diſcutient and antiſceptic fomentations; in which intention it appears to be of no inconſiderable efficacy. It has likewiſe been recommended in unguents for promoting the growth of hair; a virtue to which it does not appear to have much claim. *Lewis's Hiſtory of the Materia Medica.*

ABROTANUM *Femina*, the name of a plant called in Engliſh, lavender cotton. It is a buſhy ſhrubby plant, all over hoary; with oblong ſlender leaves, compoſed each of four rows of little knobs ſet along a middle rib; and naked, diſcous, yellow flowers ſtanding ſolitary on the tops of the ſtalks.

It is a native of the ſouthern parts of Europe; flowers in our gardens from June to near the end of ſummer; and holds its leaves all the winter.

This plant is ſuppoſed to agree in virtue with the foregoing abrotanum, and to be the moſt effectual of the two as an anthelmintic. It has been cuſtomary among the common people to uſe, in this intention, a decoction of the leaves made in milk, which receives from them a thick conſiſtence, and a ſtrong though not very diſagreeable taſte.

On careful examination, the two abrotana appeared to differ very conſiderably in quality. The femina is in ſmell weaker and leſs agreeable than the mas; in taſte, nauſeous and acrid, but void of the penetrating bitterneſs which prevails in the other. Infuſions, tinctures, and extracts prepared from the femina, are more unpleaſant than thoſe of the mas, though not bitter. The eſſential oils of the two plants, and of conſequence their diſtilled waters and ſpirits, approach nearer in flavour to one another, though not entirely alike.

Theſe differences, doubtleſs, affect their virtues as internal medicines. Nevertheleſs, for fermentations, which is the principal uſe that either of them is applied to in the preſent practice, they may be looked upon as very nearly alike: hence the college of phyſicians at London, under the name abrotanum, allow either the mas or femina to be taken indifferently. *Lewis's Hiſtory of the Materia Medica.*

ABROTONITES, a wine mentioned by Dioſcorides impregnated with abrotanum or ſouthernwood: it is recommended as a diuretic, and good in diſorders of the ſtomach, loſs of appetite, and in the jaundice.

ABRUS, a kind of kidney-bean, growing in Egypt and the Eaſt Indies.

ABSCENDENTIA, in ſurgery, decayed parts of the body, which, in a morbid ſtate, are ſeparated from the ſound, or loſe that union which was preſerved in a natural ſtate of health.

ABSCESS, in ſurgery, is a tumor containing pus or purulent matter.

All abſceſſes are the conſequences of an inflammation: the ripening of abſceſſes is promoted by means of cataplaſms, poultices, &c. The exceſſive heat of the tumor, and the throbbing pains which are felt, attended by a fever, are ſigns that the inflammation will terminate in a ſuppuration; the irregular ſhiverings, which come on upon the heightening of theſe ſymptoms, denote that the ſuppuration is forming: the abſceſs is formed when the matter is turned into pus: the diminution of the tenſion, fever, pain and heat, together with a ceſſation of the throbbing, are rational ſigns; and the ſoftening of the tumor and fluctuation are ſenſible ſigns which foretel that termination.

Abſceſſes are opened either by cauſtics or inciſion, and cannot be cured but by an evacuation of the pus: but in critical tumors, which are ſometimes occaſioned by malignant fevers, cauſtics are preferable. The application of a cauſtic fixes the humour in the part where nature ſeems to have depoſited it, and hinders reſorption, which would be dangerous, and oftentimes mortal. Cauſtics diſpoſe the part to a plentiful ſuppuration, and accelerate the formation of it; and, with this view, are uſed before the maturation is perfect: they are likewiſe applied to ſuch tumors as form themſelves ſlowly, and by congeſtion, as well as to thoſe which form in the ſhape of a cone, and whoſe circumference is hard, ſo that the converſion of the humour into pus would be either difficult or impoſſible, without their aſſiſtance.

To open a tumor by means of a cauſtic, it muſt be covered with a plaiſter, in the middle whereof is left an orifice of ſuch ſize as may be judged muſt convenient, and in which a proper potential cauſtery muſt be put, in order to be applied to the ſkin; if the cauſtic be ſolid, it muſt be wetted before it is applied. The whole is to be covered with another plaiſter, proper compreſſes, and a retentive bandage. In about five or ſix hours, more or leſs, when, according to the activity of the cauſtic, it is judged that the eſchar muſt be formed, the dreſſings are taken of, and the eſchar divided, from one end to the other, with a biſtoury; in the doing of which great care is to be taken to go down as low as the pus: after the operation, the wound is dreſſed with digeſtives, and the eſchar ſeparates in a few days with a plentiful ſuppuration. In common caſes of abſceſſes, it is beſt to divide the eſchar with an inciſion knife, obſerving to plunge it into the center of the abſceſs. When the whole length of the abſceſs is opened, the finger is introduced into its cavity; and if there be any membranes which form partitions, and divide the abſceſs into ſeveral cellulæ, they muſt be cut with the point of the ſciſſars, or with the biſtoury. In all theſe caſes, the inſtruments muſt be conducted by the end of the finger, for fear of injuring any of the parts which may be taken for membranes without that precaution: if the ſkin is very thin, it muſt be cut off with the ſciſſars or the biſtoury; though the latter inſtrument is preferable, as it occaſions leſs pain, and renders the operation quicker. The inciſion ſhould be always made at the loweſt part of the abſceſs, and the ſkin ſpaced as much as poſſible, on which account counter openings are often made when the abſceſs is very large.

ABSCISSE, or ABSCISSA, in mathematics, any part of the diameter or axis of a curve, contained between its vertex or ſome other fixed point, and the interſection of an ordinate. Such is the line A O (Plate I. *fig.* 5.) contained between the vertex A of the curve B A C, and the ordinate B O. The word is derived from the Latin *abſcindere*, to cut off, as being parts cut off from the axis—Others call them *ſagittæ*, q. d. arrows.

In the parabola, the abſciſſe is a third proportional to the parameter and the ordinate, and the parameter is a third proportional to the abſciſſe of the ordinate. See PARABOLA.

In the ellipſis, the ſquare of the ordinate is equal to the rectangle under the parameter and the abſciſſe, leſſened by another rectangle under the ſaid abſciſſe, and a fourth proportional to the axis, the parameter, and the abſciſſe.

In the hyperbola the ſquares of the ordinates are as the rectangles of the abſciſſe by another line compounded of the abſciſſe and the tranſverſe axis.

In theſe two propoſitions relating to the ellipſis and the hyperbola, the origin of the abſciſſes, or the point A, from whence they begin to be reckoned, is ſuppoſed to be the vertex of the curve, or, which amounts to the ſame, the point where the axis meets it: for if the origin of the abſciſſes be taken from the center, as is often done, then the two foregoing theorems no longer hold good.

ABSCISION, in ſurgery, is uſed in various ſenſes, but commonly to expreſs the dividing any corrupted and uſeleſs part of the body from the ſound, by means of ſome ſharp inſtrument; it is principally applied to the ſoft and fleſhy parts of the body; for this operation, with regard to the bones, is uſually ſtiled amputation.

ABSCISION, in rethoric, is a figure of ſpeech, whereby the ſpeaker ſtops ſhort in the middle of his diſcourſe.

ABSCONSA, a word frequently occurring in the Monaſt. Anglican. the decretals of archbiſhop Lanfranc, and in the writings of many eccleſiaſtics among the Engliſh and French. It ſignifies a dark lanthorn uſed by the Monks at the ceremony of burying their dead.

ABSENT, in law, implies in general any one who is gone away from his habitation.

When Nicholas Bernoulli, nephew to the famous James and John Bernoulli, maintained at Baſil, in the year 1709, his theſis for the degree of doctor of laws, he determined to pitch upon a ſubject which might give him an opportunity of diſplaying his knowledge in geometry, as well as in law; and accordingly choſe for the ſubject of this theſis *de uſu artis conjectandi*, or, the application of the doctrine of probabilities to matters of Juriſprudence; in the third chapter of which he treats of the time when the abſent perſon ſhould be conſidered as dead; and, according to that learned author, he is to be looked upon as ſuch, when there is twice as much reaſon to conclude him dead, as there is to believe him alive. See the article PROBABILITY.

ABSINTHIES *Vinum*, wine of wormwood. See ABSINTHIUM.

ABSINTHIUM, wormwood, in the materia medica, a perennial plant, having large winged and ſerrated leaves, of a ſtrong, pungent ſmell. In the beginning of July it throws out ſeveral ligneous, ſtriated, hoary ſtalks, two or three feet high, ſet with ſmall leaves, having at the top a ſpike of ſmall flowers of a pale yellow, growing many together, each incloſed in a ſmall ſquamous calix, containing very ſmall ſeeds.

The abſinthium vulgare, or common wormwood, uſually grows by the ſides of highways and foot paths; but the abſinthium Romanum is propagated in gardens, by parting the plant every ſecond year, and planting the ſlips in rows at about three feet diſtance.

Of this plant there are only four ſorts uſed in medicine, viz. *the great or Roman wormwood, the ſmall ſort or Pontic, ſea wormwood*, and the *abſinthium Alpinum*. Beſides theſe, botaniſts make twenty-eight other kinds.

The great wormwood, before it blowed, yielded by chymical analyſis, a liquid phlegm of the ſame taſte and ſmell with the plant, without any ſign either of an acid or an alkali; it was mixed with concerte urinous volatile ſalt, and a ſubtile or thick oil. The black maſs which remained in the retort, being calcined in a reverberatory, its aſhes yielded by lixiviation a fixed ſalt, which was purely alkaline.

The leaves and flower-ſpikes yielded a limpid phlegm of the ſame taſte and ſmell as the plant; this phlegm at firſt ſhewed ſome ſigns of a ſmall acidity, afterwards of a ſtrong acid, and at length of an acid and an urinous alkali, with plenty of eſſential oil; a reddiſh liquor, alkaline and full of urinous and concrete volatile ſalt; and an oil which was either ſubtile and eſſential, or thick and fœtid.

From the black maſs remaining in the retort, and afterwards calcined in a reverberating heat, were produced aſhes, that by lixiviation yielded a fixed ſalt, which was purely alkaline. The compariſon of the elements obtained, and of their quantity, has demonſtrated that the leaves of this plant contain more fine volatile parts than the flowers and ſeeds do; and that they have a great deal leſs acid ſalt and oil than the flower tops; from whence it follows, that the leaves contain an ammoniacal ſalt, and a good deal of ſubtile oil, and that in the tops we meet with a tartareous united with an ammoniacal ſalt; but it is probable that its efficacy principally depends upon its aromatic bitter and eſſential oil, and that though it may appear the ſame in the leaves and tops, yet it is nevertheleſs more ſubtile, open, and volatile in the leaves, on account of its intimate union with the volatile ſalts.

This plant is ordered in the jaundice, cachexy, and green ſickneſs; it kills worms and ſtrengthens the ſtomach: but is, like the generality of bitters, bad for the nerves. Several medicinal compoſitions are prepared from this plant; and, among others, the *abſinthites vinum*, or wormwood wine. To make it, take four pounds of the tops of each of the two firſt kinds of abſinthium, when freſh and in bloom; cleanſe, and either mince or bruiſe them, then put them together, with three drachms of powdered cinnamon, into a barrel which will contain fifty quarts: fill the barrel with muſt freſh expreſſed from the white grape, and ſet the barrel into a cellar, leaving the wine to ferment: when the fermentation is over, fill up the caſk with white wine, bottle it, and keep it for uſe.

A receipt for making *vinum abſinthites*, at any time.

Take the dried leaves of the two ſorts of wormwood, of each ſix drachms, and pour thereon two quarts of white wine; then put them together into a large bottle, and ſet them in the cool to macerate twenty-four hours; then, having ſqueezed out the leaves thoroughly, filtrate the liquor, and you will have a vinum abſinthites which you may keep for uſe.

ABSIS in aſtronomy. See APSIS.

ABSOLUTE, in a general ſenſe, implies ſomething that ſubſiſts independently of others.

The word is compounded of *ab*, and *ſolvo*, to releaſe.

ABSOLUTE *Equation*, in aſtronomy, is the aggregate of the optic and eccentric equations. The apparent inequality of a planet's motion ariſing from its not being equally diſtant from the earth at all times, is called its optic equation, and would ſubſiſt even if the planet's real motion were uniform. The eccentric inequality is cauſed by the planet's motion being uniform. To illuſtrate which, conceive the ſun to move, or to appear to move in the circumference of a circle, in whoſe center the earth is placed. It is manifeſt, that if the ſun moves uniformly in this circle, it muſt appear to move uniformly to a ſpectator on the earth, and in this caſe there will be no optic nor eccentric equation: but ſuppoſe the earth to be placed out of the center of the circle, and then, though the ſun's motion ſhould be really uniform, it would not appear to be ſo, being ſeen from the earth: (See OPTIC *Inequality*) and in this caſe there would be an optic equation, without an eccentric one. Imagine farther, the ſun's orbit to be not circular but elliptic, and the earth in its focus; it will be full as evident that the ſun cannot appear to have an uniform motion in ſuch ellipſe; ſo that his motion will then be ſubject to two equations; that is, the optic equation, and the eccentric equation. See EQUATION.

ABSOLUTE *Government* is that wherein the prince is left ſolely to his own will, not being limited by any laws. When the Danes, in 1670, made their king abſolute, they declared he was abſolved from his coronation oath.

ABSOLUTE *Gravity*, in phyſics, implies the whole force by which a body is urged downwards. See GRAVITY.

ABSOLUTE *Motion.*	See	MOTION.
ABSOLUTE *Space.*		SPACE.
ABSOLUTE *Time.*		TIME.

ABSOLUTE *Number*, in algebra, is a known quantity which poſſeſſes one intire part or ſide of an equation, being the product of the unknown roots in any equation. So in the equation $xx+16x=36$, the abſolute number is 36, being equal to the ſquare of the unknown root x added to 16 times x. Alſo in this cubic equation $x^3+20x^2-10x=100$, the abſolute number is 100, being equal to the whole other ſide of the equation x^3+20x^2-10x. This is what Vieta calls *homogeneum comparationis.* See EQUATION.

ABSOLUTE, in metaphyſics, implies a being that exiſts by neceſſity of its own nature. In which ſenſe God alone is abſolute.

ABSOLUTE is alſo an epithet applied to things that are free from limitations or conditions.

ABSOLUTION, in a general ſenſe, implies the act of pardoning or forgiving. It is granted either by a prince or magiſtrate, and ſtops the execution of juſtice.

ABSOLUTION, in civil law, is a definitive ſentence, whereby the party accuſed is declared innocent, and as ſuch ſaved from the puniſhment inflicted by the laws for the commiſſion of the particular crime with which he was charged.

ABSOLUTION, in the canon law, is a juridical act, whereby the prieſt declares the ſins of ſuch as are penitent remitted.

ABSOLUTION is chiefly uſed among proteſtants for a ſentence whereby a perſon who ſtands excommunicated is releaſed or freed from that puniſhment.

ABSORBENTS, in the healing art, is a general name for all ſuch medicines as have the power of imbibing the ſuperfluous humours in the ſtomach or inteſtines. All the teſtaceous powders, chalks, earths, calcined bones, &c. are medicines of this kind.

The word is compounded of the Latin *ab*, and *ſorbeo*, to drink. Abſorbents are chiefly given when the abſorbent humours are of the acid kind. But perhaps among this numerous claſs of remedies, there is not one equal to the magneſia alba; becauſe it not only abſorbs the acid juices, but alſo by its gentle purgative quality, carries the offending matter off by ſtool.

ABSORBENT *Veſſels*, in anatomy, are thoſe which abſorb the juices of the body. Thus the lacteals are called abſorbent veſſels, becauſe they abſorb the chyle. The cutaneous veſſels are called by the ſame name, from their abſorbing a part of the water of baths, fomentations, &c.

ABSTEMIOUS, an epithet applied to perſons who uſe a ſpare diet, but eſpecially to thoſe that abſtain from wine and all other fermented liquors.

ABSTENTION, in the civil law, implies the repudiation of an inheritance by the heir, whereby the ſucceſſion is rendered vacant, and the deceaſed inteſtate, unleſs ſome proviſion be made of a ſecond heir by way of ſubſtitution.

ABSTENTION, in the medical art, is uſed to expreſs a ſuppreſſion or retention.

ABSTERGENTS, in phyſic, are remedies of a ſaponaceous nature, capable of diſſolving reſinous concretions. Caſtellus has confounded them with abluents: but this is an abuſe of terms.

ABSTINENCE, the act of refraining from certain enjoyments; particularly from eating and drinking to exceſs.

ABSTINENCE, in phyſic, has a very extenſive meaning: by this term we underſtand a privation from all ſucculent aliments. Though abſtinence is not ſufficient for the cure of diſeaſes, yet it wonderfully aſſiſts the operation of medicines, and is a ſure preſervative againſt many diſorders. We ſhould regulate the quantity of aliments we take, by the loſs of ſubſtance ſuſtained by means of exerciſe, and the time in which perſpiration is more or leſs plentiful; and at the ſame time be careful to abſtain from ſuch aliments as we have obſerved to diſagree with our conſtitution.

According to Dr. Cheyne, moſt of the chronical diſeaſes, the infirmities of old age, and the ſhort lives of Engliſhmen, are owing to repletion; and may be either cured, prevented, or remedied by abſtinence. But the kinds of abſtinence to which we are to confine ourſelves, either in ſickneſs or health, are to be deduced from the laws of diet and regimen. See the article REGIMEN.

ABSTINENTS, or ABSTINENTES, a ſet of heretics that appeared in France and Spain about the end of the third century. They are ſuppoſed to have borrowed part of their opinions from the Gnoſtics and Manicheans, becauſe they oppoſed marriage, condemned the uſe of meats, and placed the Holy Ghoſt in the claſs of created beings.

ABSTRACT, an epithet applied to both perſons and things, implying that thoſe particulars are ſeparated from all other things by an operation of the mind called abſtraction. See ABSTRACTION.

The word is formed from the Latin *abſtractum*, compounded of *ab*, and *traho*, to take or draw.

ABSTRACT *Ideas* are the ideas or notions we acquire of ſome general quality or property, conſidered ſimple in itſelf, without the leaſt regard to any particular ſubject.

ABSTRACT *Mathematics*, otherwiſe called pure mathematics, is that which treats of magnitude or quantity, abſolutely and generally conſidered, without reſtriction to any ſpecies of particular magnitude; ſuch are arithmetic and geometry; in this ſenſe, abſtract mathematics is oppoſed to mixed mathematics, wherein ſimple and abſtract properties, and the relations of quantities primitively conſidered in pure mathematics, are applied to ſenſible objects, and by that means become intermixed with phyſical conſiderations; ſuch are hydroſtatics, optics, navigation, &c.

ABSTRACT *Numbers* are aſſemblages of units, conſidered in themſelves, without denoting any particular and determined particulars. Thus 6 is an abſtract numbet, when not applied to any thing; but if we ſay 6 feet, 6 becomes a concerte number. See the article NUMBER.

ABSTRACT *Terms*, in logic, are ſuch as denote objects exiſting in the imagination only. Thus *beauty* and *uglineſs* are abſtract terms. There are ſome objects that pleaſe and appear beautiful to us; and, on the contrary, others that affect us in a diſagreeable manner: the former we ſtile beautiful and the other ugly, though there are no ſuch real ſubſtances in nature as beauty and uglineſs; they ſubſiſt entirely in the imagination.

ABSTRACT is alſo uſed as a ſubſtantive, and implies a general view or analyſis of ſome larger work.

ABSTRACTION, in phyſic, implies that operation of the mind, whereby it forms by reflection from the ſenſible impreſſions of external objects or ſome internal affection, a ſingular conception, independently of all other ideas.

As we have no other method of communicating our thoughts than that of ſpeech, neceſſity and cuſtom induced us to give names both to real objects, and metaphyſical conceptions; and thoſe names have greatly contributed towards enabling us to diſtinguiſh theſe conceptions.

The uniform ſenſation, for inſtance, that all white objects excite in us, has led us to give the ſame qualified names to each of theſe objects; we ſay of each of them in particular, that it is white; and afterward, in order to denote the point wherein all theſe objects reſemble one another, we have coined the word whiteneſs; therefore there are, in fact, ſuch objects as we call white; but there is not, except in our imagination, any being which we term whiteneſs.

Thus whiteneſs is only an abſtract term; it is the produce of our reflection, owing to the uniformities of particular impreſſions, that ſeveral white objects have made in us; it is the point to which we refer all thoſe impreſſions which are different on account of their particular cauſe and uniform in regard to their kind.

There are objects whoſe aſpect affects us in ſuch a manner, that we call them beautiful; and afterwards conſidering that manner of affecting apart and ſeparated from every other kind of object, we call it beauty. There are particular bodies that are extended, figurate, or rather diviſible, and have ſeveral other properties. It has happened that our mind has conſidered them ſometimes ſo far only as they are extended, ſometimes as figurate, or rather diviſible; always ſtopping at one of theſe conſiderations only, which is to make an abſtraction of all the other properties. Afterwards we have obſerved, that all bodies agree with each other, ſo far as they are extended, or ſo far as they are figurate, or rather ſo far as they are diviſible: and therefore, in order to denote theſe different points of conformity or reunion, we form to ourſelves all idea either of extent, figure, or diviſibility; and yet there is no ſuch phyſical exiſtence as can be called either extent, figure, or diviſibility, and nothing elſe.

We may diſpoſe as we think proper of every particular body that is in our power; but are we likewiſe maſter of extent, figure, or diviſibility, or is an animal, in general, of any country? and can it tranſport itſelf from one place to another?

Each particular abſtraction excludes the conſideration of every other property. If you conſider the body, ſo far as figurative, it is evident that you do not regard it either as luminous or living: you take nothing away from it. Thus it would be ridiculous to conclude from your abſtraction, that this body, which your mind only regards as figurate, could not be at the ſame time in itſelf extended, luminous, living, &c.

Abſtract ideas are then as it were the point to which we refer the different impreſſions, or particular reflections which are of the ſame kind, and from whence we remove all that is not preciſely ſo.

Such is man, he is a living being, capable of feeling, thinking, judging, reaſoning, willing, diſtinguiſhing every ſingle act of each of theſe faculties, and by thoſe means of making abſtractions.

We ſhall obſerve, under the head ARTICLE, that not having any thing in this world but real beings, it has not been poſſible that each of thoſe beings ſhould have had a proper name.

A common name has been given to all individuals that reſemble each other, and this is called by the name of ſpecies, becauſe it agrees with every individual of one kind. Peter is man, and Paul is man; Alexander and Cæſar were men. In this ſenſe the name ſpecies is only an adjective like beautiful, good, true, &c. and upon that account there is no article joined with it. But if we regard the man, without making any particular application of the word, then the man is taken in an abſtract ſenſe, and becomes one ſpecific individual, and for that reaſon it is that the article is added; and thus it is we ſay the beautiful, the good, the true. Theſe ſimple ſpecific abſtracts have not however been obſerved; from man has been formed humanity; from beautiful, beauty; and ſo of others.

Thee ſchoolmen, who found both the one and the other of theſe names eſtabliſhed, have called thoſe concrete, which we name ſpecific individuals; ſuch as, the man, the beautiful, the good, the true. This word concrete comes from the Latin *concretus*, and ſignifies that which grows with, is compoſed, or formed, of; becauſe theſe concretes, ſay they, are formed from thoſe which they name abſtracts; ſuch are humanity, beauty, goodneſs, truth. Thoſe philoſophers have held, that as light comes from the ſun, and water grows hot only by fire, ſo in like manner man was not ſuch but by humanity; that the beautiful was not beautiful but by beauty; the good was ſo by goodneſs; and that we have true only from truth.

They have ſaid humanity, from thence man, and ſo in like manner beauty, and afterwards beautiful. But we are not thus inſtructed by nature, ſince ſhe at firſt ſhewed us phyſics only. We began with ſeeing men, long before we either comprehended or formed to ourſelves the abſtract term humanity. We have been touched with beautiful and good, before we knew how to underſtand or form the words beauty and goodneſs: and men have been penetrated with the reality of things, and have felt an internal perſuaſion, before they introduced the word truth; they have compriſed, and they have conceived, before they knew the word underſtanding; they have willed, without knowing how to ſay they had a will; and they have remembered, before they could form the word memory.

Men ſet out with making obſervations upon the uſe, ſervice, and placing of words; and after that they invented the word grammar.

Thus grammar is, as it were, the center or point of reunion, to which the different obſervations that have been made on the uſe of words are referred. However, grammar is no more than an abſtract term, and a mere metaphyſical name; for there is no ſuch real ſubſtance as grammar, and none but grammarians have obſerved it. It is exactly the ſame thing with reſpect to the names of arts and ſciences, as well as thoſe of their different parts.

In like manner, the point to which we bring the ſeveral obſervations that have been made in relation to the good and bad uſe we can make of the faculties of our underſtanding, is called logic.

We have ſeen ſeveral creatures ceaſe to live, and on this intereſting conſideration have been quite confounded; we have obſerved the uniform ſtate of inaction wherein they all continue, when they no longer live; and, having conſidered that ſtate independently of all particular application, and as being in itſelf ſomething real, we have called it death, though death is not a real being. It is thus that different privations, as well as the abſence of thoſe objects, whoſe preſence make either agreeable or diſagreeable impreſſions on us, have excited in us a reflected ſenſe of theſe privations and abſence, and given us room to form to ourſelves an abſtract conception, even of nothing; for we underſtand ourſelves perfectly well, when we maintain that nothing has no properties, that nothing cannot be the cauſe of ſomething, and that we know nothing, or privations, only by the abſence of the realities to which they are oppoſed.

The reflection on this negation convinces us that, if we may be allowed the expreſſion, we are ſenſible of what we cannot perceive.

We have then a conception of nothing, and this conception is an abſtraction which we expreſs by a metaphyſical name, and in the manner of other conceptions: and thus it is that, as we uſe the expreſſions to take a man out of priſon, or to take a crown out of our pocket, ſo we ſay, by way of imitation, that God has taken the world out of nothing.

The cuſtom we daily have of giving names to the objects of ideas, which repreſent real ſubſtances to us, has induced us to give them likewiſe, by way of imitation, to the metaphyſical objects of abſtract ideas, of which we have a conception; and hence it is that we ſpeak of them in the ſame manner as we do of real objects.

Illuſion, figure, and falſhood, have a language in common with truth. The expreſſions which we ourſelves make uſe of to convey to others either the ideas which we have within ourſelves of real objects, or of ſuch as are but ſimple abſtractions of our mind, have a perfect analogy with one another. We ſay death, ſickneſs, imagination, idea, &c. as we ſay, the ſun, the moon, &c. though death, ſickneſs, idea, &c. are not exiſting ſubſtances; and we ſpeak of the phoenix, chimera, ſphinx, and the philoſopher's ſtone, in the ſame manner as we ſpeak either of the lion, panther, rhinoceros, Africa, or Peru.

Even proſe, though with leſs ornament than poetry, realizes and forms perſons of theſe abſtract beings, and equally miſleads the imagination. If Malherbe has ſaid, that death has its terrors, that he ſtops his ears, that he leaves us to cry out, &c. do not our proſe writers always uſe ſimilar expreſſions, that death reſpects no one, to wait for death, the martyrs have dared death, have ſought death; to meet death without emotion, the image of death, to face death; death does not ſurpriſe a wiſe man: neither have we a more popular expreſſion, than that death is never ſatisfied, or that death is never in the wrong.

The heathens realized love, diſcord, fear, ſilence, health, *dea ſolus*, &c. and made ſo many divinities of them. And nothing is more common with us than to realize an employment, place, or dignity: we make perſons of reaſon, taſte, genius, temper, and the paſſions of humour; character, virtues, and vices; as well as of the mind, heart, fortune, misfortune, reputation, and nature.

The real beings which ſurround us, are moved and governed in ſuch a manner as is known to God alone, and according to thoſe laws which he thought fit to eſtabliſh when he created the world: thus God is a real term, but nature only a metaphyſical one.

Although a muſical inſtrument, upon the touching of its ſtrings, in itſelf receives but a ſimple modification, when it gives the ſound re or ſol; yet we ſpeak of theſe ſounds as if they were ſo many real beings: and in the manner that we ſpeak of our dreams, imaginations, ideas, pleaſures, &c. as if we actually dwelt in a real and phyſical country. And in truth, if we may uſe the expreſſion, we actually ſpeak the language of the country of abſtractions.

We are ſenſible that we are moved, affected, and agitated, and the more ſo, as we perceive that we are ſenſible; and this has firſt occaſioned us to give names to different kinds of particular ſenſations, and afterwards to the general ones of pleaſure and grief; and yet there are no ſuch real ſubſtances as either pleaſure or grief.

Poets have amuſed the imagination by realizing abſtract terms; and by that means have deceived the people. But has not Plato himſelf, who baniſhed the poets from his republic, been miſled by ideas that were nothing more than the abſtractions of his own mind.

Philoſophers, metaphyſicians, and, if we may be permitted to ſay it, even the geometricians themſelves, have been miſled by abſtraction, the former by eſſential forms and occulent virtues, and the latter either by privation or attractions. The metaphyſical point, for example, as well as length, is no more than a mere abſtraction. We may conſider the diſtance between one town and another, and be totally employed with that diſtance; we may likewiſe conſider the ſpot from whence we ſet out, and that at which we are arrived. We can even by imitation and compariſon look upon a ſtraight line in no other light than as the ſhorteſt way between two points; and yet theſe two points are no more than the extremities of the line itſelf; and, by an abſtraction of my mind, conſider theſe extremities only as terms, and ſeparate whatever elſe is not ſo; the one is the term where the line begins, the other where it ends: thoſe terms we call points, and fix to that conception the preciſe idea of term only, taking away every other idea; here then is neither ſolidity, length, nor depth, but the abſtract idea of term only.

The names of real objects, are the primary, and, if we may be allowed the expreſſion, the very firſt-born among names: the others, which only expreſs the conceptions of our minds, are no more than names by imitation or adoption; they are thoſe of our metaphyſical conceptions: thus the names of real objects, as ſun, earth, moon, &c. might be called phyſical, and the others metaphyſical names.

Phyſical terms then are of uſe to ſhew that we ſpeak of real objects; whereas a metaphyſical name denotes that we ſpeak only of ſome particular conception of our mind: and therefore when we ſay the ſun, the earth, the ſea; that man, that horſe, that ſtone, &c. our own experience, as well as the concurrence of the juſteſt motives, perſuade us, that there are ſuch real objects as the ſun, earth, &c. and that if theſe objects were not real, our forefathers would never have coined thoſe names, nor ſhould we have adopted them: ſo when we ſay, the nature, fortune, proſperity, health, ſickneſs, death, &c. the vulgar, by imitation, believe that there is, independantly of their manner of thinking, ſome being which we call nature, another ſtiled fortune, and ſo on: for they do not imagine that all men would ſay, the nature, fortune, life, death, &c. when there was no ſuch real object as nature, fortune, &c. as if we could have neither conceptions or imaginations, unleſs there had been real objects which were the exemplars of them.

In truth, we cannot have theſe conceptions, unleſs ſomething real gives us room to form them; but the word which expreſſes conception has not, except within ourſelves, any proper examplar. We have ſeen gold, and obſerved mountains; and, if theſe two repreſentations give us room to form to ourſelves an idea of a mountain of gold, it by no means follows from this image, that there has been ſuch a mountain. A ſhip ſhall be ſtopped in the open ſea by ſome ſand-bank, which is unknown to the ſailors, and they ſhall imagine that it is ſome fiſh which has ſtopped them; but this imagination does not give any reality to the ſuppoſed fiſh; nor any way prevents whatever the ancients believed of a remora from being a fable, like thoſe they have imagined of the phœnix, and thought of the ſphinx, chimera, and the horſe Pegaſus. Senſible people have found it difficult to believe that there have been men ſo irrational as to realize their own abſtractions. But, among other inſtances, we might refer to the Hiſtory of Valentinian, the arch-heretick of the ſecond century of the church: this man was a Platonic philoſopher, who deviated from the ſimplicity of the faith, and imagined æons, i. e. abſtract beings, which he realized, as ſilence, truth, intelligence, &c. He began to ſpread his errors in Egypt, and went afterwards to Rome, where he gained ſeveral diſciples, who were from him called Valentinians. Tertullian wrote againſt theſe hereticks. Thus the abſtractions of the primitive times have opened a door to diſputes, which have not been leſs violent for their being frivolous.

Finally, if we would avoid abſtract terms, we muſt be obliged to have recourſe to circumlocutions and paraphraſes, which enervate the diſcourſe. Beſides, theſe terms fix the mind; they aſſiſt us in introducing order and preciſion in our thoughts, give more grace and energy to diſcourſe, render it more lively, compact, and forcible; and, in ſhort, highly deſerve that we ſhould be acquainted with their juſt value.

Abſtractions are in diſcourſe what certain ſigns are in arithmetic, algebra, and aſtronomy: but when we do not attend to their value, or to give or take them for what they are really worth, they miſguide the mind from the reality of things, and ſo become the ſource of a multiplicity of errors.

We would therefore adviſe, that, in the didactic ſtyle, that is, when we are teaching and inſtructing, we ſhould make uſe of abſtract terms, and figurative expreſſions, with the greateſt circumſpection. For inſtance, we would not have any one ſay in logic, the incloſed idea; nor, when we judge of or compare ideas, that we ſhould unite or ſeparate them, ſince idea is no more than an abſtract term. We likewiſe uſe this expreſſion, the ſubject attracts the attribute to itſelf, in which there are nothing but metaphors that merely amuſe the imagination. Neither ſhould we ſay, in grammar, that the verb governs, wills, requires, rules, &c.

ABSTRUSE, ſomething deep, hidden, concealed, or far removed from common apprehenſions, and therefore not eaſily underſtood; in oppoſition to what is obvious and palpable.

The word is formed from the Latin *abſtruſus*, compounded of *abs*, from, and *trudo*, to thruſt; q. d. placed beyond the reach of common capacities.

Thus metaphyſics is an abſtruſe ſcience; and the doctrine of fluxions, and the method de maximis and minimis are abſtruſe points of knowledge.

ABSURD, an epithet applied to any thing that oppoſes the human apprehenſion, and contradicts a manifeſt truth. Thus, it would be abſurd to ſay that ſix and ſix make only ten, or to deny that twice ſix make twelve. When the term abſurd is applied to actions, it has the ſame import as ridiculous.

Reductio ad ABSURDUM, a method of proving the truth of a propoſition, by ſhewing that the contrary is abſurd. This method of reaſoning is often uſed by Euclid in his Elements of Geometry.

ABSURDITY, an impropriety, or ſomething that oppoſes an evident truth or principle. The contradiction is the greateſt of all abſurdities.

ABSUS, in botany, an Egyptian plant, which bears a flower of a whitiſh colour, tinged with a paliſh yellow: it grows to the heighth of about four fingers, and has a leaf like the trefoil. Mr. Ray is of opinion, that the abſus is the Egyptian lotus.

ABSYNTHIUM. See the article ABSINTHIUM.

ABTHANES, a title of honour uſed by the ancient inhabitants of Scotland, who called their nobles *thanes*, which in the old Saxon ſignifies *king's miniſters*; and of theſe the higher rank were ſtiled *abthanes*, and thoſe of the lower *underthanes*.

ABUCATUAIA, the Braſilian name of a fiſh, called by the Portugueſe peixe-gallo. It has ſome reſemblance to a doree, and is of the ſize, ſhape, and thickneſs of a flounder; but the mouth is ſmall, and without teeth. The iris of the eye is of a ſilver colour, and there are two long threads which hang from the lower part of the body, and a ſingle one on the back, near the back fin. It is without ſcales, and all over of a ſilver colour, except the threads, which are black. *Brookes's Natural Hiſt.*

ABUNA, the title given to the archbiſhop of Abyſſinia.

ABUNDANT *Number*, in arithmetic, is a number, the ſum of whoſe aliquot parts is greater than the number itſelf. Thus the aliquot parts of 12, being 1, 2, 3, 4, and 6, they make, when added together, 16. An abundant number is oppoſed to a deficient number, or that which is greater than all its aliquot parts taken together; as 14, whoſe aliquot parts are 1, 2, and 7, which make no more than 10: and to a perfect number, or one to which its aliquot parts are equal, as 6, whoſe aliquot parts are 1, 2, and 3. See ALIQUOT and NUMBER.

ABUNDANCE, ABUNDANTIA, a heathen divinity repreſented on ancient monuments under the figure of a woman with a pleaſing aſpect, crowned with garlands of flowers, pouring all ſorts of fruit out of a horn which ſhe holds in her right hand, and ſcattering grain with her left, taken promiſcuouſly from a ſheaf of corn. On a medal of Trajan, ſhe is repreſented with two cornucopias.

ABUSE, in a general ſenſe, implies the preverting ſomething from its genuine or original intention. Thus an abuſe of words is the uſing them without any clear and diſtinct ideas.

ABUTILON, in botany, the name of a plant with a monopetalous, campiform flower, very open and indented; from the bottom there ariſes a pyramidal fiſtula, generally charged with ſtamina. The piſtil adheres to the calyx, and is fixed like a nail in the lower part of the flower and fiſtula. The piſtil becomes a fruit, reſembling the capital of a column, and is compoſed of ſeveral ſmall capſulæ placed round an axis, each capſulæ being inſerted into the ſtria of the axis. Theſe capſulæ open in two parts, and contain kidney-ſhaped ſeeds. *Turnefort.*

ABYSS, in a general ſenſe, denotes ſomething very profound, and as it were bottomleſs.

The word is originally Greek ἀβυσσὸς, compounded of the privative α and βυσσὸς, bottom, i. e. without a bottom. Suidas and others give different origins; as from α and ϐυω, to cover, to hide, or from α and δυω, &c. But the more judicious critics reject them, as but one degree better than that of the old ſcholiaſt, who derives abyſſus from *ad ipſus*, becauſe the waters flow thither in abundance.

Abyſs is alſo uſed to denote an immenſe cavern of the earth, where God collected all thoſe waters on the third day; which, in our verſion, is rendered the deep, and elſewhere the great deep.

In the language of the Holy ſcripture abyſs is made uſe of to expreſs hell, the greateſt deeps of the ſea, and the chaos that was covered with darkneſs at the beginning of the world, and upon which the ſpirit of God moved, or was carried, Geneſis, chap. i. ver. 2. The ancient Hebrews believed, as the major part of the eaſtern people do to this day, that the abyſs, ſea, and heavens, encompaſſed the whole earth; which, ſay they, was as it were plunged into and floated upon the abyſs, pretty much as a melon ſwims half above and half below water. They likewiſe believe that the earth was founded upon the waters, or at leaſt that it had its foundation in the abyſs. Under the waters, and at the bottom of this abyſs, it is that the ſcriptures repreſent to us the giants groaning and ſuffering puniſhment for their crimes. There it is that the Rephaims, thoſe ancient giants, who in their life-times made mandkind tremble, are confined. In ſhort, it is within theſe dark dungeons that the prophets ſhew us the kings of Tyre, Babylon, and of Egypt, who are there buried, and yet live to expiate their pride and cruelties.

We are likewiſe told that theſe abyſſes are the habitations of devils and the wicked. I ſaw, ſays St. John in the Revelations, a ſtar fall from heaven; and to him was given the key of the pits of the abyſs, or of the bottomleſs pit. *Calmet's Dict.*

ABYSS, in antiquity, is a name given to the temple of Proſerpine.

ACACIA, in antiquity, is a kind of bag, or long ſtrait roll. The conſuls and emperors, from the time of Anaſtaſius, are repreſented on medals with one of theſe in their hands. Some writers take it for a handkerchief rolled up, which the emperor made uſe of to give the ſignal for beginning the games. Others, particularly M. du Cange, think it a bundle of memoirs, which were preſented to him; and ſeveral imagine it a bag of earth, which the emperors held in one hand, as they did at the ſame time a croſs in the other, whereby they were reminded, that how great ſoever they were, yet that they muſt one day be reduced to duſt. The bag or acacia was ſubſtituted in the ſtead of the mappa, or napkin, which the emperor, conſul, or other magiſtrate, had in his hand, and made uſe of to give the ſignal in the games.

ACACIA, in botany, is the name of a tree that bears leguminous flowers and leaves in pairs, oppoſite to each other: the piſtil riſes out of the calyx, is enveloped with a ſerrated membrane, and ſucceeded by a flat pod, divided into two parts, containing ſeveral ſeeds in ſhape like a kidney: the leaves of the acacia are placed in pairs on one ſide of the ſtalk, which is terminated by a ſingle leaf.

American ACACIA is a tree common in that part of the world. It does not grow to any great height; its wood is hard and rough, its foliage long, but ſmall, and affording but little ſhade, and its branches are full of thorns: this tree being a quick grower, and in the ſpring bearing cluſters of very agreeable flowers, is proper to be planted in clumps of flowering ſhrubs, and in wilderneſs quarters. Its branches being very ſubject to hang down, and trail upon the ground, it is cuſtomary to prop them, but this greatly disfigures the tree: the acacia is propagated by ſeed.

ACAICA, in the materia medica, an inſpiſſated gummy juice, of a brown colour without, and either blackiſh, reddiſh, or yellowiſh within: it is of a firm conſiſtence, hard and melting in the mouth, has an auſtere aſtringent taſte, but is not diſagreeable. This juice is generally made up into little round lumps of four, ſix, or eight ounces weight, wrapped up in thin bladders, and is brought from Egypt. They eſteem that ſort to be the beſt which is new made, pure, and clean, and eaſily diſolves in water. This juice is expreſſed from the immature pods of a tree called *acacia folio ſcorpioidis leguminoſæ*. It is a large tree, very full of branches; its roots divide themſelves into ſeveral ramifications, ſpreading on all ſides, and its trunk is often a foot diameter, and equals, or rather ſurpaſſes the other ſorts of acacia in height: it is firm, loaded with branches, and armed with thorns; its leaves are ſlender, conjugated, and ranged in pairs in one ſide of a rib or pedicle, of the length of two fingers; they are of a dark green, about three lines in length, and ſcarce one in breadth; the flowers appear before the leaves, in form of a ſpherical bud, ſupported by a pedicle an inch in length; they are of a gold colour, and have no ſmell. Each flower conſiſts of one entire piece, reſembling a thin tube, which is protuberant at the top, and divided into five ſegments; they are adorned with a great quantity of ſtamina, and a piſtil ſucceeded by a pod, ſomething like that of a lupine, about five inches long, brown or reddiſh, flat, and of the thickneſs of a line towards the middle, but thinner on the edges; they are of an equal breadth, and ſo ſtrongly compacted at equal diſtances, that each pod repreſents ſix, eight, ten, or ſometimes more, flat piſtils tied together by a thread: their greateſt breadth is half an inch, and not above a line in the middle;

middle; the cavity of the pode is filled with a flat, hard, oval ſeed, leſs than that of the ſervice-tree, of a cheſnut colour, marked with a line round it like tamirand ſeeds, and covered with a gummy mucilage, of a reddiſh colour, and an aſtringent or acid taſte: this tree is common about Grand Cairo. They waſh the pods in water before they are ripe, bruiſe them and expreſs their juice, which they boil to a proper conſiſtence, and then lay it in little heaps. This juice analized yields a moderate portion of acid ſalt, a very little alkaline ſalt, a great deal of aſtringent earth, and a large quantity of oil. It is placed among the incraſſants and repellent aſtringents, prevents vomiting, and ſtops hæmorrhages and fluxes of the belly. The doſe is from ʒ ß. to ʒ j. given either in powder, bolus, or any liquid vehicle: the Egyptians give a drachm of it diſſolved in any liquid every morning, to ſuch as are troubled with ſpitting of blood.

Acacia *Germanica*, the inſpiſſated juice of wild ſloes gathered before they are fully ripe. It is often uſed as a ſuccedaneum for the Egyptian acacia.

ACACIANS, a name given to a particular ſect of the Arians, from Acacius of Cæſarea, who was their chief.

ACADEMICS, a ſect of philoſophers who followed the doctrine of Socrates and Plato, with regard to the uncertainty of human knowledge, and the incomprehenſibility of truth.

Academic, taken in this ſenſe, amounts to much the ſame with what we call Platoniſt, the only difference between them being that of commencement. The ancients who embraced Plato's ſyſtem were called academici, academics; whereas thoſe that followed the ſame opinions ſince the reſtoration of learning, have taken the denomination of Platoniſts.

It may be ſaid, that Socrates and Plato, who laid the firſt foundations of the academy, were not ſo erroneous as thoſe who ſucceded them: we mean Arceſilas, Carneades, Clitomachus, and Philo. Socrates indeed profeſſed to know nothing: but his doubts aroſe from phyſics only, which he at firſt diligently cultivated, and which he afterwards acknowledged to ſurpaſs the reach of human underſtanding; if he ſometimes ſpoke in the language of the ſceptics, it was out of irony or modeſty, in order to pull down the vanity of the ſophiſts, who fooliſhly boaſted, that they were ignorant of nothing, and always ready to diſpute on all manner of ſubjects.

Plato, the father and inſtitutor of the academy, who was inſtructed by Socrates in the art of doubting, and was likewiſe his avowed diſciple, confined himſelf to his own manner of treating ſubjects, and undertook to oppoſe all the philoſophers who had preceded him: but, by recommending to his diſciples a diffidence of themſelves, and to doubt of every thing, he did not intend to leave them fluctuating between truth and error; but to put them on their guard againſt thoſe raſh and precipitate deciſions, ſo natural to youth, and prevent their falling into error, by freely examining every thing without prejudice.

Arceſilas undertook to reform the ancient academy, and erect a new one. It is ſaid that he imitated Pyrrho, and converſed with Timon: ſo that, having enriched Pyrrho's art of doubting, with the elegant erudition of Plato, and armed it with the dialects of Diodorus, Arioſto compared him to a chimera, and with great pleaſantry applied to him the verſes, where Homer ſays, that "She was a lion before, a dragon behind, and a goat "in the middle." Thus, according to him, Arceſilas was Plato before, Pyrrho behind, and Diodorus in the middle; for which reaſon ſome rank him in the number of the ſceptics; and Sextus Empiricus maintains, that there is but a very ſmall difference between his ſect, or the ſceptic, and that of Arceſilas, called the new academy.

He taught, indeed, that we do not even know whether we know any thing; that nature has not given us any rule of truth; that human underſtanding and the ſenſes are incapable of comprehending truth; that he found in every thing reaſons oppoſed by an equal force; and, in a word, that all things are immerſed in darkneſs, and conſequently that we muſt always ſuſpend our aſſent. His doctrine was not much applauded, becauſe he ſeemed deſirous of extinguiſhing every ray of ſcience, of throwing darkneſs on the mind, and overturning the foundations of philoſophy. Lacydes was the only perſon who defended the doctrine of Arceſilas: he tranſmitted it to Evander, one of his diſciples, and Evander tranſmitted it to Hegeſimus, who handed it down to Carneades.

Carneades however did not follow the doctrine of Arceſilas in every particular, though he retained its principal tenets: this made him paſs for the author of a new academy, which was called the third. He oppoſed with great wit and eloquence, all the opinions propoſed to him, without diſcovering his real ſentiments. He firſt made Rome acquainted with the power of eloquence and the merit of philoſophy; and that flouriſhing ſtate, attracted by the novelty and excellence of ſo noble a ſcience, followed Carneades with ſo much eagerneſs, that Cato, a man in all other reſpects of an excellent judgment, but deficient in politeneſs, grew jealous of this new kind of erudition, which had the power of captivating the affections of mankind. Cato declared in the ſenate, that they ought to grant Carneades, and the deputies which accompanied him, whatever they demanded, and ſend them inſtantly back with honour to their country.

His eloquence was ſo powerful, that he overturned whatever he undertook to oppoſe, confounded reaſon by reaſon itſelf, and remained invincible in the opinions he maintained. The ſtoics, a contentious and ſubtle people in diſputations, and with whom Carneades and Arceſilas had frequent conteſts, found it very difficult to eſcape the ſnares he laid for them: and therefore, in order to diminiſh his reputation, they aſſerted that all he alledged againſt them was taken from the books of Chryſippus the ſtoic. Carneades, to whom Cicero allows the art of refuting every thing, modeſtly allowed, that, without the help of Chryſippus, he ſhould have done nothing; and that he would engage Chryſippus with his own weapons.

The corrections which Carneades made in the doctrine of Arceſilas are very trifling: it is eaſy to reconcile what Arceſilas ſaid, "that he found no truth in things," with what Carneades advanced, "that he did not deny "there being ſome truth in things; but that we have "no rule whereby to diſcern it; for there are two "kinds of truth, the one what we call truth of exiſt"ence, the other truth of judgment." It is therefore plain that thoſe two propoſitions of Arceſilas and Carneades regard the truth of judgment. But the truth of judgment is in the number of relative things, which ought to be conſidered as having a relation to our mind; when therefore Arceſilas ſaid, there was nothing true in things, he meant, that there was nothing in things that the human mind could know with certainty; and this is exactly the ſame with what Carneades maintained.

Arceſilas ſaid, that nothing could be comprehended, and that all things were obſcure. Carneades granted, that nothing could be comprehended, but did not, for that reaſon, allow that all things were obſcure; becauſe probable things were not, in his opinion, obſcure. But though he made ſome difference in expreſſion, he made no difference in effect; for Arceſilas did not maintain, that all things are obſcure otherwiſe than as they cannot be comprehended, nor did he diveſt them of all ſemblance of truth or probability: this was alſo the ſentiment of Carneades; for when he ſaid, that things were not ſo obſcure, but we might diſcern thoſe which ought to be preferred for the purpoſes of life, he did not pretend that they were clear enough to be comprehenſible: it follows therefore that there was no diverſity of ſentiment between them, when Carneades permitted the wiſe man to entertain opinions, and perhaps even ſometimes to teſtify his own conſent: and when Arceſilas forbid both the one and the other, Carneades only aſſerted, that the wiſe man ought, for the common purpoſes of life, to make uſe of probable things, without which he could not live; but not in the conduct of the mind, and in the ſearch after truth; and whence only Arceſilas baniſhed both opinion and conſent. Conſequently their differences conſiſted in expreſſions only, and not in the things themſelves.

Philo, the diſciple of Clitomachus, who had himſelf been a pupil of Carneades, deſerved to be ſtiled with Charmides, “the founder of the fourth academy,” as he differed in ſome points from the ſentiments of Carneades: for he aſſerted, that things are in themſelves comprehenſible, though we are unable to comprehend them.

Antiſchus was the founder of the fifth academy. He had been ſeveral years a diſciple of Philo, and maintained the doctrine of Carneades; but, in the decline of life, he quitted his maſter's party, and introduced into the academy the tenets of the ſtoics, which he attributed to Plato, maintaining that the doctrine of the ſtoics was not new, but a reformation of the ancient academy. This fifth academy therefore was only an aſſociation of the ancient academy, and the philoſophy of the ſtoics; or rather the ſtoical philoſophy dreſt in the habit of the old academy, which flouriſhed under Plato and Arceſilas.

Some have indeed pretended that there was only one academy: for as the ſeveral branches which ſpring from the ſame root, and ſpread themſelves on different ſides, are not different trees; ſo all thoſe ſects which ſprung from the ſingle ſtock of the doctrine of Socrates, *that man knows nothing*, though divided into ſeveral ſchools, are no more than one academy. But if we examine attentively, we ſhall diſcover ſo remarkable a difference between the old and new academies, that we muſt neceſſarily acknowledge two academies; the old, or that of Socrates and Antiochus, and the new, which was founded by Arceſilas, Carneades, and Philo: the firſt was dogmatical in ſome points, the firſt principles and ſome moral truths at the leaſt were therein honoured and reſpected; whereas the new one almoſt entirely approached to ſcepticiſm.

ACADEMY, in antiquity, was anciently a garden or villa, ſituated in one of the ſuburbs of Athens, about a mile from the city, where Plato and his followers held their aſſemblies to converſe on philoſophical ſubjects. This place gave the denomination to the ſect of academics.

This villa had the name of academy given to it from one Academus, or Ecademus, a citizen of Athens, who was originally the owner of it, and made it a kind of gymnaſium. He lived in the time of Theſeus.

Cimon embelliſhed the academy, and adorned it with fountains, trees, and walks, for the convenience of philoſophers and men of learning, who here aſſembled to confer together and diſpute upon different ſubjects. It was alſo the burial-place of thoſe illuſtrious men who had done any ſignal ſervice to the republic. Sylla however paid no reſpect to this aſylum of the polite arts; for, during the ſiege of Athens, he employed thoſe very trees which formed the walks of the academy, to make engines of war to batter the place.

Cicero had alſo a villa or place of retirement near Puzzuoli, to which he gave the name of Academy, and where he uſed to entertain ſuch of his friends as had a taſte for philoſophical converſations. It was there he compoſed his *Academical Queſtions*, and his books *De Natura Deorum*.

ACADEMY alſo ſignifies a ſect of philoſophers who maintained, that truth is inacceſſible to our underſtanding; that all knowledge is uncertain; and, therefore, that a wiſe man ought always to doubt and ſuſpend his judgment, without ever poſitively aſſerting or denying any thing: in this ſenſe, academy is the ſame thing as the ſect of Academics. See ACADEMICS.

ACADEMY, among the moderns, is commonly uſed to ſignify a ſociety of learned men, eſtabliſhed for the culture and advancement of arts and ſciences.

Some authors confound academy with univerſity; but, though they are much the ſame in Latin, they are two different things in Engliſh.

An univerſity is properly a body compoſed of graduates in ſeveral faculties; of profeſſors, who teach in the public ſchools; of regents or tutors, and ſtudents who learn under them, and aſpire likewiſe to the ſame degree: whereas an academy is not intended to teach or profeſs any art, ſuch as it is, but to improve it; it is not compoſed of novices, to be inſtructed, but of thoſe who are more knowing; of perſons of a diſtinguiſhed capacity to confer and communicate their lights and diſcoveries to each other for their mutual advantage.

The firſt academy we read of was that eſtabliſhed by Charlemaign, at the motion of Alcuin. It was compoſed of the chief wits of the court; and the emperor himſelf was one of the members. In their academical conferences every perſon was to give an account of what ancient writers he had read; and each academician aſſumed the name of ſome ancient author, or of ſome celebrated perſon of antiquity. Alcuin, among the reſt, from whoſe letters we learn theſe particulars, took that of Flaccus, the ſirname of Horace: a young lord, whoſe name was Angilbert, took upon him that of Homer; Adelard, biſhop of Corbie, called himſelf Auguſtin; Raculphe, archbiſhop of Mentz, was Dametis; and the king himſelf David.

This may ſerve to correct a miſtake in ſome modern writers, who relate that it was in conformity with the genius of the learned men of thoſe times, who were great admirers of Roman names, that Alcuin took that of Flaccus Albinus.

Moſt nations have at preſent academies, Ruſſia not excepted: but Italy excels in this reſpect, at leaſt in point of number. There are but few in England; the chief and only ones that merit any great attention, are called by theſe names, viz. the Royal Society, and the Society of Antiquaries of London. See ROYAL *Society*, and ANTIQUARIAN *Society*. See alſo SOCIETY *for the Encouragement of Arts*, &c.

There are, however, beſides theſe, an academy of muſic, and another of painting, each governed by their reſpective directors.

In France there are flouriſhing academies of all kinds, ſeveral at Paris, and ſome in the provincial towns, of which the following are the chief:

French ACADEMY, inſtituted in the year 1635, by cardinal Richelieu, in order to perfect the French tongue. Its principal buſineſs is, in general, all matters of grammar, poetry, and eloquence: its form is very ſimple, and has never been altered. The members are forty in number, and not one of them has any ſuperiority over the reſt. No nobleman, or man of diſtinction, can be admitted into it upon any other account than that of being a man of letters: for cardinal Richelieu, who was well appriſed of the great advantages ariſing from parts, was deſirous that the mind ſhould keep pace with rank and nobility.

This academy has a director and a chancellor, who are drawn by lot every three months, and a ſecretary, who is perpetual. They meet at the Old Louvre three times a week, viz. on Mondays, Thurſdays, and Saturdays, all the year round. They have no public aſſemblies, except when they receive ſome new academician, and that held annually on St. Lewis's day, when the academy diſtributes the prizes of eloquence and poetry, each of which conſiſts in a gold medal. This academy has publiſhed a dictionary of the French language. Their motto is, *à l'immortalité*.

Royal ACADEMY *of Inſcriptions and Belles Lettres* was eſtabliſhed by Lewis XIV. who conſidered that it would be highly advantageous to France, to eſtabliſh an academy, whoſe whole employment ſhould be that of forming inſcriptions, devices, and medals, and diffuſe over thoſe monuments an elegant taſte, and that noble ſimplicity which conſtitutes its undoubted worth. The firſt ſociety conſiſted of a ſmall number, choſen out of the members of the French academy, who, upon their eſtabliſhment, met in the library of M. Colbert, from whom they received his majeſty's orders.

The days of their meetings were not determined; but they were commonly on Wedneſdays, eſpecially in the winter ſeaſon. In ſummer they often retired to Sceaux, in order to render their conferences more harmonious, and that the miniſter might himſelf enjoy the pleaſure of their company with more tranquility.

It is ſaid that the ſubject of the deſigns for the king's tapeſtry, publiſhed in the collections of prints, was a ſpecimen of the labours of this academy.

At length they undertook to compoſe, by means of medals, a connected hiſtory of the principal events of Lewis XIV's reign. This was an ample field of matter, but very great difficulties attended the execution. The ancients, of whom there are ſo many medals remaining, have left us no other rules than the medals themſelves, which had hardly before that time been conſidered, except for the ſake of the beauty of the impreſſion, or ſtudied only for the attainment of hiſtorical knowledge. The moderns, who had during the two laſt centuries, ſtruck a great many medals, had given themſelves but little trouble about rules, having neither followed nor preſcribed any. Beſides, it was difficult to find, in the collections of this ſort, three or four pieces, where genius had, with any ſucceſs, ſupplied the deficiency of method.

This academy was alſo directed to cauſe the plans and principal views of the royal houſes to be engraved, together with the deſcriptions of them. Theſe were very far advanced, and the deſcriptions almoſt all drawn up, when M. Colbert died.

They were likewiſe ordered to cauſe the plans and views of conquered places to be engraved, and to add thereto an hiſtory of each town and conqueſt; but neither this project nor the former has been ſince purſued. M. Colbert died in the year 1683, and was ſucceeded by M. de Louvois in the poſt of ſuperintendant of the buildings. That miniſter, knowing that the abbé Tallemont had orders to prepare the inſcriptions ordered to be placed under the pictures of the gallery at Verſailles, and that he intended they ſhould appear upon the king's return, ſent for him immediately, to Fontainbleau, where the court then reſided, in order to inform him exactly of the preſent ſtate of things. The abbé Tallemont accordingly gave him the account, and ſhewed him the inſcriptions, which were all ready. Theſe inſcriptions were accordingly placed in the palace of Verſailles; but they have ſince undergone ſeveral alterations.

M. de la Chapelle being made comptroller of the buildings after M. Perrault, was directed to be preſent at the meetings of this academy, in order to write down their deliberations, and thereby became the fifth academician. Soon after that, M. de Louvois added to them two other academicians, viz. M. Racine and M. Deſpreaux, whoſe aſſiſtance he thought would be neceſſary to the academy, in preparing the medallic hiſtory. At length M. Rainſant, who was a gentleman well verſed in the knowledge of medals, and director of the king's cabinet of antiquities, made the eighth academician.

They now, with great ardour, reſumed the medallic hiſtory, which had been interrupted during the laſt years of M. Colbert. They ſtruck ſeveral of different ſizes, and moſt of them larger than thoſe coined ſince: for which reaſon they are now called *medals of the great hiſtory.*

In the year 1691, the king gave the inſpection of the academy to M. de Pontchartrain, comptroller general, ſecretary of ſtate, ſuperintendant to the king's houſhold, and afterwards chancellor of France. This gentleman, who had a taſte for literature, gave particular attention to this little academy, which was now generally known by the name of the *Royal Academy of Medals and Inſcriptions.* He fixed their meetings on Tueſdays and Saturdays.

The medals were now carefully reviewed; a great number added; all of them were reduced to one ſize; and the hiſtory brought down to the advancement of the duke of Anjou to the crown of Spain.

The eſtabliſhment of the academy of inſcriptions could not fail of having a place in this celebrated work, wherein none of the academies had been forgot. The medal on this ſubject repreſents Mercury ſitting and writing with an antique ſtylus upon a table of braſs; he leans with his left hand upon an urn full of medals, and at his feet are ſeveral others placed upon a card. Legend, *Rerum geſtarum fides*; and on the exergue, *academia regia inſcriptionum et numiſmatum inſtituta*, M. DC. LXIII. ſignifying, that the royal academy of medals and inſcriptions, founded in 1663, ought to give, to future ages, a faithful teſtimony of all great actions.

Soon after the publication of the medallic hiſtory, the academy received a new regulation, bearing date the 16th of July, 1701. It is now compoſed of *ten honorary members*, *ten penſionaries*, *ten aſſociates*, each of whom has two declarative voices, and ten *eleves*, or pupils. They meet every Tueſday and Wedneſday in one of the halls of the Louvre, and have two public meetings yearly, one on the day after Martinmas, and the other on the 16th after Eaſter. Its vacations are the ſame as thoſe of the Academy of Sciences. They have ſome correſponding aſſociates, who may be either inhabitants of France, or foreigners. They have likewiſe a preſident and vice-preſident, choſen out of the honorary members, and a director and ſub-director taken out of the penſionaries.

The claſs of eleves has been ſince ſuppreſſed and united to the aſſociates. The ſecretary and treaſurer are perpetual; and the academy, ſince its revival in 1701, has publiſhed ſeveral volumes; theſe contain, excluſive of ſuch memoirs as are thought proper to be publiſhed intire, extracts made by the ſecretary from ſeveral others, and the eulogies on the deceaſed members. The preſident Darcy de Noinville, about ſix and twenty years ago, founded a literary prize, conſiſting of a gold medal of the value of 400 livres, which is every year diſtributed by the academy. The motto of the academy is, *Vetat mori.*

Royal ACADEMY *of Sciences.* This academy was eſtabliſhed in the year 1666, by the care of M. Colbert. Lewis XIV. after the peace of the Pyrennees, being deſirous of eſtabliſhing the arts, ſciences, and literature, upon a ſolid foundation, directed M. Colbert to form a ſociety of men of known abilities and experience in the different branches of literature and ſcience, who ſhould meet together under the king's protection, and communicate their reſpective diſcoveries. M. Colbert, having conferred on this ſubject with thoſe who were moſtly celebrated for their learning, reſolved to form a ſociety of ſuch perſons as were converſant in natural philoſophy and mathematics, to join them to other perſons of ſkill in hiſtory and other branches of erudition, and to add ſuch as were entirely engaged in what are peculiarly called the Belles-Lettres, grammar, eloquence, and poetry. It was ordered that the geometricians, and natural philoſophers, ſhould meet on Tueſdays and Saturdays, in a great hall of the king's library, in which were contained the books of mathematics and natural philoſophy: that the learned in hiſtory ſhould aſſemble on Mondays and Thurſdays, in the hall wherein the books of hiſtory were depoſited: and, laſtly, that the *claſs* of Belles-Lettres ſhould aſſemble on Wedneſdays and Fridays; and that all the differerent claſſes ſhould meet together upon the firſt Thurſday in every month; and, by their reſpective ſecretaries, make a report of the proceedings of the foregoing month.

But an academy of this kind could not long ſubſiſt upon ſuch a footing; and, therefore, the claſſes of Belles-Lettres and hiſtory were reunited to the French academy; ſo that there only remained the claſſes of natural philoſophy and mathematics. The mathematical claſs was compoſed of Meſſ. Carcavy, Huyghens, de Roberval, Frenicle, Auzout, Picard, and Buot; and the natural philoſophers were Meſſ. de la Chambre, his majeſty's phyſician in ordinary; Perrault, Duclos, and Bourdelin, chemiſts; Pequet and Gayen, anatomiſts; Merchant, a botaniſt; and Duhamel, their ſecretary.

Theſe learned men, as well as their ſucceſſors, have publiſhed ſeveral excellent works for the advancement of the ſciences; beſides which, the academy, in the years 1692 and 1693, publiſhed every month ſeveral ſeparate tracts, which had been read at their meetings during the courſe of thoſe years.

In 1696, the abbé Bignon, who had long preſided in the Academy of Sciences, thought it might be rendered of greater utility by giving it a new form. This he mentioned to his uncle the chancellor Pontchartrain; and the academy, at the beginning of that year, received a new regulation, which entirely altered the firſt form. By this regulation, the academy is compoſed of ten honorary members, one of whom muſt be the preſident, twenty penſioners, three geometricians, three aſtronomers, three mechanics, three anatomiſts, three botaniſts, three chemiſts, a treaſurer and a ſecretary, who are both perpetual; twenty aſſociates, twelve of whom muſt be inhabitants of France; two geometricians, two aſtronomers, &c. eight foreigners; and twenty eleves, each of whom is attached to one of the penſionary academiſts.

The honorary and penſionary members alone have deliberative voices when elections, or other affairs relating to the academy, are upon the tapis: but, when any thing relative to ſcience is treated of, the aſſociates are joined with them: the eleves are not to ſpeak, except called upon by the preſident.

The honorary members muſt be inhabitants of France, and well verſed in mathematics and natural philoſophy. In this claſs only regulars or religious are to be admitted.

No member can be admitted a penſionary, unleſs well known on account of ſome conſiderable work, important diſcovery, or remarkable courſe of ſtudy.

Every penſionary member is obliged to declare, at the beginning of the year, what work he intends to proſecute that year. Beſides this, the penſionaries and aſſociates are obliged, in their turns, to produce ſome obſervations and memoirs. The aſſemblies are held on Wedneſdays and Saturdays, unleſs either of them happens to be a holiday, and then the aſſembly is to be held on the preceding day.

In the year 1716, the duke of Orleans, then regent of the kingdom, thought proper to make ſome alterations in this regulation; and accordingly the claſs of eleves was ſuppreſſed, it appearing to be attended with ſome inconveniencies, particularly that of making too great an inequality among the academiſts, and being productive of ſome animoſities and miſunderſtanding among the members. At the ſame time he created two other claſſes, one conſiſting of twelve adjuncts, who, as well as the aſſociates, were allowed a deliberative voice in matters relative to ſcience; and the other of ſix free aſſociates, who are not attached to any particular ſcience, nor obliged to purſue any particular work.

This academy, ſince its re-eſtabliſhment in 1699, has been very exact in publiſhing every year a volume, containing either the works of its own members, or ſuch memoirs as have been compoſed and read to the academy during the courſe of that year. To each volume is prefixed the hiſtory of the academy, or an extract of the memoirs, and, in general, of whatever has been read or ſaid in the academy: at the end of the hiſtory are the elogiums on ſuch academics as have died in the courſe of that year.

The late M. Rouillé de Meſlay, counſellor to the parliament of Paris, founded two prizes, one of 2500, and the other of 2000 livres, which are diſtributed by the academy alternately every year; the ſubjects of the firſt muſt relate to phyſical aſtronomy, and thoſe for the latter to navigation and commerce.

The academy has for its motto, *Invenit et perficit.*

Beſides theſe academies eſtabliſhed in the capital, there are many others in the provinces, particularly at Thoulouſe, Bourdeaux, Soiſſons, Marſeilles, Lyons, Pau, Montauban, Angiers, Amiens, Villefranche, &c.

Royal ACADEMY *of Sciences and Belles Lettres of Pruſſia.* This academy was eſtabliſhed by Frederic I. king of Pruſſia, in the year 1700, and M. Leibnitz appointed the firſt preſident, when the liſt of the members was adorned with ſome of the greateſt names in the republic of letters. This academy, in the year 1710, publiſhed the firſt volume of its tranſactions, under the title of *Miſcellanea Berolinenſia*; and, though Frederic's ſucceſſor gave but little encouragement to letters, the academy continued to publiſh new volumes in the years 1723, 1727, 1734, and 1740. At length Frederic III. the preſent king of Pruſſia, thought proper to give new vigour to the academy; and accordingly invited to Berlin ſuch foreigners as were of the moſt diſtinguiſhed merit in literature, and encouraged his ſubjects to proſecute the ſtudy and cultivation of the ſciences, by giving ample rewards; ſo that, in the year 1743, there appeared a new volume of the *Miſcellanea Berolinenſia,* in which the additional force the academy had acquired plainly appeared. However, that prince did not think fit to confine himſelf there: he thought that the Royal Academy of Sciences of Pruſſia, in which, till that time, ſome miniſter or opulent nobleman had preſided, would find an advantage from having a man of letters at its head, and accordingly conferred that honour on M. Maupertuis, a gentleman well known in every part of Europe. At the ſame time the king gave a new regulation to the academy, and took upon him the title of its protector. This academy has, ſince the year 1743, publiſhed thirteen volumes of memoirs, wrote in French, and nearly upon the ſame plan as the hiſtory of the Royal Academy of Sciences at Paris; but with this difference, that, in the ſecond of theſe volumes, the extracts of the memoirs are ſuppreſſed, as they were intended to be in the future volumes, one of which they propoſed to publiſh every year. The academiſts hold two public aſſemblies annually; one in January, on the preſent king's birth-day; and the other in May, on the day of his acceſſion to the throne. At the latter of theſe aſſemblies is given as a prize a gold medal of fifty ducats value: the ſubject for this prize is ſucceſſively natural philoſophy, mathematics, metaphyſics, and erudition: for the academy has this in particular, that it includes metaphyſics, logic, and morality, which are not the objects of any other; there being in this academy a particular claſs engaged in metaphyſical diſquiſitions, called the claſs of ſpeculative philoſophy.

Imperial ACADEMY *of Peterſburg.* The Czar Peter I. ſirnamed the Great, by whoſe means Ruſſia ſhook off the yoke of barbariſm, which had reigned ſo many ages in that kingdom, coming into England and France in the year 1717, and obſerving the great utility of literary ſocieties and academies, reſolved to eſtabliſh one in his capital; and had actually taken the neceſſary meaſures for that purpoſe, when death put a period to his life in the year 1725. His ſucceſſor, the Czarina Catherine, being fully informed of his intentions, laboured upon the ſame plan, and in a ſhort time formed one of the moſt celebrated academies in Europe, compoſed of the moſt conſiderable foreigners, ſome of whom ſettled at Peterſburg. This academy, which is employed in cultivating the ſciences and polite literature, hath, ſince the year 1726, publiſhed thirteen volumes of memoirs, wrote in Latin, and are highly valuable, particularly for the mathematical part, which contains a great number of excellent pieces. Moſt of the foreigners who compoſed that academy being either dead or retired out of the kingdom, it was in a very languiſhing condition when the Czarina Elizabeth aſcended the Ruſſian throne: but that princeſs, happily for herſelf, named count Raſomowſki preſident; who gave the academy a new body of ſtatutes, and left nothing neglected which could re-eſtabliſh its ancient ſplendor. This academy has this modeſt motto, *Paulatim.*

Royal Spaniſh ACADEMY is an academy for cultivating the Caſtilian tongue, eſtabliſhed at Madrid, on the model of the French academy. The deſign of this ſociety was laid by the duke d'Eſcalona, and approved of by the king in 1714, who declared himſelf its protector. It conſiſts of twenty-four academiſts, including the director and ſecretary. Its device is a crucible on the fire, with this motto, *Limpia fija y da eſplendor.*

ACADEMY *of Naturæ curioſi,* in Germany, was firſt founded in 1652, by Mr. Bauſch, a phyſician, and taken, in 1670, under the protection of the emperor Leopold.

Italy alone has more academies of note than all the reſt of the world; not a city but furniſhes a ſet of learned perſons for an academy, which to them ſeems an eſſential part of a regular conſtitution. Jarckius has given us a ſpecimen of their hiſtory, printed at Leipſic in 1725.

Jarckius's account goes no farther than to the academies of Piedmont, Ferrara, and Milan; in which laſt city he reckons twenty-five; but adds a liſt of all the reſt, to the number of five hundred and fifty.

ACADEMY *of Painting* is a public ſchool to which the painters reſort, either to draw or paint, and where the ſculptors model after a naked perſon, which they call a model.

The Royal Academy of Painting and Sculpture at Paris, took its riſe from the diſputes that happened among the maſter-painters and ſculptors in that capital. This induced Le Brun, Sarazin, Corneille, and others of the king's painters, to form the deſign of a particular academy; and, having preſented a petition to the king, they obtained an arret, dated the 20th of January 1648. Their meetings were at firſt held in the apartments of M. Charmois, ſecretary to the marſhal Schomberg, who drew up the firſt body of ſtatutes for the academy.

Afterwards the academy conferred in the houſe of a friend of M. Charmois, ſituate near St. Euſtachius's;

from whence they removed to the hotel de Cliſſon, where they continued their exerciſes till the year 1653, when the academiſts removed into the ſtreet des Dechargeurs. In the year 1654, and towards the beginning of 1655, they obtained from cardinal Mazarin a brevet and letters patent, which were regiſtered in parliament; and, in grateful acknowledgment for this favour, they choſe the cardinal for their protector, and the chancellor for their vice-protector.

It is remarkable, that the chancellor had, from the firſt inſtitution of the academy, been named its protector; but, in order to make his court to cardinal Mazarin, he declined that title, and contented himſelf with that of vice-protector.

In the year 1656, Sarazin granted to the academy an apartment, which he at that time had in the galleries of the Louvre; but they were obliged to quit it in the year 1661: and M. de Ratabond, ſuperintendant of the buildings, removed them to the Palais-royal, where they remained one and thirty years. At length the king gave them an apartment in the Old Louvre.

In the year 1663, the academy obtained, by means of M. Colbert, a penſion of 4000 livres.

This academy conſiſts of a protector, a vice-protector, a director, a chancellor, four rectors, adjuncts to the rectors, a treaſurer, forty profeſſors, one of which is profeſſor of anatomy, and another of geometry; ſeveral adjuncts and counſellors, a ſecretary and hiſtoriographer, and two uſhers.

The Academy of Painting holds a public aſſembly every day for two hours, after noon, to which the painters reſort, either to deſign or paint; and where the ſculptors model after a naked perſon. There are twelve profeſſors, each of whom keeps the ſchool for a month; and there are twelve adjuncts to ſupply them in caſe of need. The profeſſor upon duty places the naked man, who is called the model, in ſuch a poſition as he thinks proper, and ſets him in two different attitudes every week: this is what they call ſetting the model. In one week of the month he ſets two models together, which is what they call ſetting the group. The paintings and models made after this model, as well as the copies made from them, are called academies, or academy figures. They have likewiſe a woman who ſtands for a model in the public ſchool. Every three months, three prizes for deſign are diſtributed among the eleves or diſciples, as are two others for painting, and two for ſculpture, every year. Thoſe who gain the prizes of painting and ſculpture are ſent to Rome, at the king's expence, to ſtudy there and complete themſelves in their art.

Beſides the Royal Academy, there are two other ſchools, or academies, of painting at Paris; one whereof is at the royal manufacture of the Gobelins: this ſchool is under the direction of artiſts, to whom the king allows an apartment in the royal hotel of the Gobelins, and who generally are members of the Royal Academy. The other is the Academy of St. Luke, which is maintained by the company of maſter-painters and ſculptors, and was eſtabliſhed by the provoſt of Paris, on the 12th of Auguſt 1391. Charles VII. in the year 1430, granted to it ſeveral privileges, which were confirmed in the year 1584, by Henry III. and in 1613, the companies of painters and ſculptors were united. This company hath at preſent a houſe near St. Denis de la Chartre, where their office is held; and a public academy carried on in the ſame manner as the Royal Academy, and where they every year diſtribute, among their diſciples, three prizes for deſigns.—The only academy we have in England of this kind is in St. Martin's-Lane, London.

ACADEMY *of Architecture*, a company of ſkilful architects, eſtabliſhed at Paris in the year 1671, by Mr. Colbert, under the direction of the ſuperintendant of the buildings.

ACADEMY is alſo uſed in ſpeaking of the ſchools and ſeminaries of the Jews, where their rabbins and doctors inſtructed the youth of their nation in the Hebrew language, and explained to them the Talmud and the ſecrets of the Cabala. The Jews have always had theſe ſorts of academies ever ſince their return from Babylon: thoſe of Tiberias and Babylon have been the moſt celebrated.

ACADEMY is alſo particularly underſtood of a riding-ſchool, or a place where young gentlemen are taught to ride the great horſe: as alſo the uſe of arms, dancing, vaulting, &c. This is what Vitruvius calls ephebeum; and ſome others, among the ancients, gymnaſium; the moderns call it equeſtrian, or military academy.

The duke of Newcaſtle will have the art of riding to have had its origin in Italy; and the firſt academy of this ſort to have been eſtabliſhed at Naples, by Frederic Griſon, who, he adds, was the firſt that wrote on this ſubject, which he did like a true cavalier and a good maſter. Henry VIII. ſays the ſame author, called over two Italians, diſciples of Griſon, into England, who ſoon ſtocked the nation with ecuyers, or riding-maſters.

He adds, that the greateſt maſter which Italy ever produced, was a Neapolitan, called Pignatelli; that La Broue rid under him five years, Pluvinel nine, and S. Antoine many years; and that theſe Frenchmen filled France with French maſters, which, till then, had known only Italians.

The ground ſet apart in an academy for riding, is called the manege, having uſually a pillar in the center, and other pillars placed two by two at the ſides.

ACADEMY *Figures*, in painting, are deſigns made after a model with a crayon or pencil.

ACAJA, in botany, a tree growing naturally in Brazil to the height of a lime: its bark is rough, and of a light aſh colour, like elder; the leaves, which are ſmooth, gloſſy, and ſhining, are placed oppoſite to each other, of unequal ſizes, but in general about four fingers in length, and a finger and a half or two fingers broad, with a broad nerve running the whole length of them. This tree bears yellowiſh flowers, which are ſucceeded by plums, not unlike ours in figure and magnitude, of a yellowiſh colour, and an acid taſte, each containing a ligneous ſtone, which is eaſily cracked, and incloſes a kernel of a yellowiſh white colour. Its wood is red, and as light as cork.

ACAJOU, *the Caſſue, or Caſhew Nut-Tree*, in botany, a kind of plant producing a monopetalous flower, in the ſhape of a funnel, and divided into ſegments; out of the calyx ariſes a piſtillum, ſurrounded with threads, or ſtamina, faſtened to an oviary at the bottom of the flower: this oviary afterwards becomes a ſoft fruit, at the extremity whereof is a capſula, in the form of a kidney, incloſing a ſeed of the ſame form.

The acajou grows every where in Malabar, though it is a native of Brazil. They make a drink of the juice of this tree, which inebriates like wine. The kernel of the nut, when roaſted, is very good to eat; but the ſhell is ſo acrimonious, that it excoriates the gums, in caſe you attempt to bite it.

The dyers uſe the oil which they expreſs from the ſhells of the nut of this tree, in dying a black colour. The inhabitants of Brazil reckon their age by means of thoſe nuts, for which purpoſe they lay up one of them every year.

ACAMATOS, a word uſed to denote the beſt conſtitution and ſhape of the human body.

ACAMECH, among ſome of the old chymiſts and minerologiſts, is uſed to denote the ſcoria of ſilver, as alſo a ſuperfluity of the humidum radicale in that metal.

ACANACEÆ, in botany, all thiſtles that are prickly and have heads, are ſo called.

ACANGIS, i. e. *ravagers or adventurers in queſt of fortune*; a name given by the Turks to their huſſars, who, like ours, are light troops, fitter for ſkirmiſhing and pillaging than to engage with regular troops in an action; they are generally ſent out in detachments to get intelligence, harraſs the enemy, attack convoys, and ravage the country.

ACANTHA, in botany, a name given to prickly or thorny plants.

The word is Greek, and ſignifies a thorn.

ACANTHA, in anatomy, ſignifies the protuberances of the back-bone, commonly called *ſpinæ dorſi*.

ACANTHACEOUS, an epithet applied by botaniſts to plants of the prickly kind.

The word is formed from the Greek, ἄκανθα, a thorn.

ACANTHABOBES, in ſurgery, a kind of forceps uſed in extracting of thorns, ſplinters, &c.

The word is compounded of the Greek, ακανθα, a thorn, and βαλλω, to caſt out, or extract.

ACANTHUS, in botany, a plant producing an irregular, monopetalous flower, terminated in a ring at the bottom: the anterior parts, and the poſterior, are in the ſhape of a ring. The place of the upper lip is filled with ſtamina, whoſe ſummits are like a bruſh; out of the calyx proceeds a piſtil, which is inſerted into the ovary at the bottom of the flower, and becomes a fruit in the ſhape of an acorn, which is enveloped by the calyx; this fruit is divided by a partition into two cells, each containing ſeeds, which are commonly of an irregular figure.

The leaves of this plant, when freſh gathered, yielded by analyſis a phlegm which had neither ſmell nor taſte, but was impregnated with a little blackiſh ſalt that rendered a ſolution of lead turbid; a liquor which at firſt inclined to an acid, and afterwards became clearly ſo, and at the ſame time a little alkaline; a reddiſh empyreumatic liquor, lightly acid, but replete with an urinous alkaline ſalt, a great deal of volatile ſalt, and an oil, neither very fluid nor very thick. The black maſs that remained in the retort, being calcined in a reverberating heat, yielded a whitiſh aſh, from which a fixed ſalt, merely alkaline, was extracted by lixiviation; from this analyſis, the relative quantity of principles extracted from it, and the viſcoſity of the plant, it appears that it contains a good deal of ſal ammoniac, and a little oil diluted in a large quantity of phlegm. They only uſe the leaves in lotions, fomentations, and cataplaſms.

Botaniſts diſtinguiſh five ſpecies of acanthus. This plant is called in Engliſh, brank urſine, bear's breech, or bear's foot.

ACANTHUS, in architecture, an ornament reſembling two ſpecies of plants of the ſame name, one of which is wild, and the other cultivated in gardens. The firſt is called in Greek acantha, which ſignifies a thorn; and is that which the major part of the Gothic ſculptors have imitated in their ornaments. The ſecond is called in Latin branca urſina, becauſe they pretend that it reſembles a bear's foot. The ancient and modern ſculptors have preferred the latter, and made uſe of it particularly in their capitals. Vitruvius ſays, that this plant gave occaſion to Callimachus, the Grecian ſculptor, to compoſe the Corinthian capital. See CAPITAL.

ACARA, a ſmall Braſilian fiſh, about three inches in length, and its body reſembling that of a perch. The mouth is narrow, and the jaws as rough as a file. The eyes are not large, but have a golden circle, and the back fins connected together. The tail is oblong, and the ſcales are pretty large, of a ſilver colour, but on the head, back, and ſides, they are mixed with umber. In the middle of each ſide there is a large black ſpot, as alſo near the root of the tail. It is a river fiſh, and keeps conſtantly in freſh water. *Brookes's Natural Hiſtory.*

ACARA-AYA, a fiſh, found plentifully on the coaſt of Braſil. It is three feet in length, and is of the ſhape of a carp. The teeth are ſharp and ſmall, but there are two more long and thick on the upper jaw. The eyes are large, with a blood-red circle without, and ſilver-coloured within. The fins are as in the former, and the tail is broad, and almoſt divided into two horns. The ſcales are middle ſized, and of a ſilver colour, ſhaded with another of the colour of blood. The belly is entirely white; but all the fins are of a blood colour, except ſome part of the belly-fins, which are white; but their extremities are of the former colour. *Brookes's Natural Hiſtory.*

ACARA-MUCA, the name of a remarkable fiſh, about ſix inches long and two broad, furniſhed with triangular teeth. Juſt behind the eyes, on the ridge of the back, ſtands a ſlender pointed horn, of a cylindrical ſhape, and two inches long. It is found on the coaſt of Braſil, but never eaten.

ACARA-PEBA, a ſmall Braſilian fiſh, about a foot long, and four or five inches broad. Its mouth is large, but without teeth, and its tail forked. It ſeems to be a ſpecies of the ſmaris.

ACARA-PITOMBA, a beautiful Braſilian fiſh, reſembling our mullet, and near two feet in length. Its tail terminates in two oblique horns. Along the middle of each ſide runs a broad and beautiful gold-coloured line, from the gills to the tail. Its back alſo down to this line is variegated with ſpots of the ſame colour; while its ſides below that line are decorated with ſhort longitudinal lines of a ſomewhat paler colour. Its belly is white, and its fins yellow.

AGARA-PUCA, a river fiſh found in Braſil, half a yard in length, and four or five inches broad. The ſnout is ſharp at the end, and the mouth is without teeth. The eyes are large, with an iris mixed with white and brown. Every part ſhines with ſmall ſcales of a ſilver-colour, only on the back there is a little mixture of gold. On each ſide there are ſix oblong bluiſh red ſpots, which are not very conſpicuous, and the back-fins, as well as the tail, are of a light blue, and ſo are the ſide fins. There are two at the bottom of the belly, which, with thoſe near the vent, are a little yellowiſh. *Brookes's Natural Hiſtory.*

ACARAUNA, a Braſilian fiſh, covered with blackiſh ſcales. The tail is forked, and on the length of the whole back, as alſo on the bottom of the belly, there runs a ſharp fin, which towards the hinder part, is about an inch broad. The mouth is ſmall, narrow, and furniſhed with exceeding ſmall teeth; and, on each ſide near the tail, there is a ſharp ſpine or prickle, almoſt an inch long, which he can conceal in his ſide, or thruſt out ſo as to wound other fiſh.

The ſquare ACARAUNA, a Braſilian fiſh, called by ſailors, the Old Wife. It differs in many things from the former: for the fore part of the body is of a ſtraw-colour, and the latter brown; beſides, the ſcales run parallel to each other; and, on both ſides the upper jaw, there are four ſpines or prickles; and on the lower two ſpikes, which are ſtiff, ſharp, and an inch in length, like a cock's ſpurs, turning obliquely downward. There is a black fin which runs from the head to the tail, and another on the belly, which proceeds from the vent to the ſame place, being parallel to each other, the fiſh being of a ſquariſh ſhape.

The ſmall Black ACARAUNA is beautifully painted with yellow belts. It differs little from the former, except in the belts, which are of an iron-grey-colour, and are ſomewhat differently placed; beſides, in theſe there are no viſible ſcales. *Brookes's Natural Hiſtory.*

ACARI, the name of inſects that breed under the ſkin. Ariſtotle calls the ſmall inſects that breed in wax by the ſame name.

ACARICABA, in botany, a Braſilian plant, whoſe roots are aromatic, and may be placed in the firſt claſs of aperitives.

ACARUS, the ſame with Acari. See ACARI.

ACARON, the name of the god of flies. The Ekronites called him Beelzebub.

ACARON, in botany, wild myrtle or butcher's broom. It is principally uſed in obſtructions of the liver, &c.

ACATALECTIC, in ancient poetry, ſignifies complete verſes, or ſuch as have all their feet and ſyllables, and are not lame or defective at the end.

The word is compounded of the Greek α priv. κατα, and ληγω, to end, q. d. that wants nothing at the end.

ACATALEPSY, among the ancient philoſophers, implied the impoſſibility of conceiving or comprehending a thing.

The word is Greek, and compounded of α priv. and καταλαμϐανω, to diſcover.

ACATASTATOS, a term uſed by the ancient phyſicians to ſignify irregular fevers, where paroxyſms are uncertain, and the appearance of the urine perpetually changing.

The word is Greek, and compounded of α priv. and καθιϛημι, to be fixed.

ACATERY, an officer in the king's houſhold, deſigned as a cheque between the clerks of the kitchen and the purveyors.

ACATIUM, a ſort of boat, or pinnace, very ſharp at the head, uſed by the ancients in military affairs.

The word is Greek, ακατιον, from ακη, a point.

ACAULIS, in botany, a term applied to plants, whoſe flowers reſt on the ground, having no caulis or ſtalk.

The word is Latin, and compounded of *a* neg. and *caulis*, a ſtalk.

ACBAB, the name of a bird reſembling our common hen, frequently found wild in the Philippine iſlands.

ACCA-LARENTIA, a pagan goddeſs of the Romans. She was the wife of Fauſtulus, ſhepherd to king Numitor, and nurſe of Romulus and Remus. Romulus, out of gratitude, decreed her divine honours after her death, and appointed a feſtival, called from her Larentalia; which was celebrated, according to Varro, in April; but according to Ovid, in December.

ACCEDAS *ad curiam*, in law, a writ which lies for him who has received falſe judgment, or fears partiality in a court-baron, or a hundred court. It is directed to the ſheriff, and iſſued out of chancery; but returnable into the king's-bench, or common pleas. In the regiſter of writs, it is ſaid to be a writ which lies as well for judgment delayed, as for falſe judgment; and that it is a ſpecies of writ, *Recordare*, the ſheriff being obliged to make record of the ſuit in the inferior court, and certify it into the king's court.

Accedas *ad vicecomitem* is a writ directed to the coroner, commanding him to deliver a writ to the ſheriff, who having a pone delivered to him ſuppreſſes it.

ACCELERATED implies, in a general ſenſe, quickened, continually increaſing. Thus, accelerated motion is a motion continually increaſing.

The word is Latin, *acceleratus*, compounded of *ad*, to, and *celer*, ſwift.

Accelerated *Motion*, in mechanics, is that whoſe velocity is conſtantly increaſed; and, if the acceſſions of velocity be equal in equal times, the motion is ſaid to be uniformly accelerated. This comes chiefly under conſideration, in the deſcent of heavy bodies, by the force of gravity. See **Motion**, **Center**, and **Velocity**.

The acceleration of falling bodies, though a moſt obvious and indiſputable fact, yet various are the ſyſtems and opinions which philoſophers have produced to account for it: ſome have aſcribed it to the preſſure of the air: the farther, ſay they, a body falls, the greater weight of atmoſphere is of conſequence incumbent on it, and the preſſure of a fluid is proportional to the perpendicular altitude thereof; to which they add, that the whole body of the fluid preſſing in innumerable right lines, all alternately meeting in the earth's center, that point muſt ſuſtain, as it were, the preſſure of the whole maſs, conſequently the nearer a body approaches thereto, the more muſt it receive of the preſſure of a multitude of lines tending to unite in the central point. Others inſiſt, that the incumbent air is the groſſer and vaporous the nearer the earth, and filled with more heterogeneous particles, which are not true elaſtic air; and hence, ſay they, a deſcending body, meeting continually with leſs reſiſtance from the elaſticity of the air, and having the ſame force of gravity ſtill acting on it, muſt neceſſarily be *accelerated*. Hobbes endeavours to account for this *acceleration*, from a new impreſſion of the cauſe which makes bodies to fall, which, on his principles, is alſo the air. As part of this aſcends, part alſo muſt deſcend, for reaſons drawn from the motion of the earth, which is compounded of two motions, one circular, and the other progreſſive, conſequently the air aſcends, and circulates at once. As the body, in its fall, receives a new preſſure in every point of its deſcent, its motion, he ſays, muſt needs be accelerated.

But to both theſe ſyſtems, it may be anſwered, that the air is quite out of the queſtion; for it is very evident that bodies fall, and in falling have their motion accelerated in vacuo as in open air. See **Vacuum**.

The Gaſſendiſts aſſign another reaſon for the acceleration. They pretend that there are continually iſſuing out of the earth certain attractive corpuſcles, directed in an infinite number of rays; thoſe, they ſay, aſcend and then deſcend, in ſuch ſort, that the nearer a body approaches to the earth's center, the more of theſe attractive rays preſs upon it; in conſequence of which, its motion becomes more *accelerated*.

The Peripatetics account for this matter thus: the motion of heavy bodies downwards, ariſes out of an intrinſic principle, ſay they, which cauſes a tendency in them to the center, as the place appropriate to their element; where, when they can once arrive, they will be at perfect reſt; wherefore, continue they, the neareſt bodies approach to it, the more the velocity of their motion is increaſed.

The Carteſians account for the *acceleration*, by the repeated impulſes of their *materia ſubtilis*, acting continually upon falling bodies, and propelling them downward.

After all, the cauſe of *acceleration* is nothing myſterious; the principle of gravitation, which determines the body to deſcend, determining it to be *accelerated* by a neceſſary conſequence. See **Gravitation**.

A body then having once begun to deſcend through the impulſe of gravity, that ſtate is now, by Sir Iſaac Newton's firſt law, become as it were natural to it, inſomuch that, were it left to itſelf, it would for ever continue to deſcend, even though the firſt cauſe of its deſcent ſhould ceaſe. But, beſides this determination to deſcend, impreſſed upon it by the firſt cauſe, which would be ſufficient to continue the degree of motion already begun to infinity, new impulſes are continually ſuperadded by the ſame cauſe, which continue to act upon the body already in motion, in the ſame manner as if it had remained at reſt: there being then two cauſes of motion, acting both in the ſame direction, it neceſſarily follows, that the motion which they unitedly produce, muſt be more conſiderable than what either could produce ſeparately; and, as long as the velocity is thus increaſed, the ſame cauſe ſtill ſubſiſting to increaſe it yet more, the deſcent muſt of neceſſity be continually accelerated.

Suppoſing then that gravity, from whatever principle it proceeds, acts uniformly upon all bodies at the ſame diſtance from the center of the earth; dividing the time which the heavy body takes up in falling to the earth into infinitely ſmall equal parts, this gravity will impel the body towards the center of the earth, in the firſt infinitely ſhort inſtant of the deſcent. If, after this, we ſuppoſe the action of gravity to ceaſe, the body will continue perpetually to advance uniformly towards the earth's center, with an infinitely ſmall velocity, equal to that which reſulted from the firſt impulſe. But then, if we ſuppoſe that the action of gravity does continue in the ſecond inſtant, the body will receive a new impulſe towards the earth equal to that which it received in the firſt inſtant, conſequently its velocity will be doubled; in the third inſtant it will be tripled; in the fourth, quadrupled; and ſo on. For the impulſe made in any preceding inſtant, is no ways altered by that which is made in the following one; but they are accumulated on each other: wherefore, the inſtants of time being ſuppoſed infinitely ſmall, and all equal, the velocity acquired by the falling body will be in every inſtant, as the times from the beginning of the deſcent, and conſequently the velocity will be proportional to the time in which it is acquired.

Moreover, the ſpace run through by a moving body during a given time, and with a given velocity, may be conſidered as a rectangle compounded of the time and the velocity. Suppoſe A (plate I. *fig.* 6.) to be the heavy body which deſcends, A B the time of the deſcent, which let be divided into a certain number of equal parts, denominated intervals or proportions of the given time, as A C, C E, E G, &c. Imagine the body to deſcend, during the time expreſſed by the firſt of the diviſions A C, with a certain uniform velocity ariſing from the degree of gravity acting on it, this velocity will be repreſented by A D, and the ſpace run through by the rectangle C A D. Now the action of gravity having produced in the firſt moment, the velocity A D, in the body before at reſt; in the ſecond moment it will produce the velocity C F, the double of the former; in the third moment, to the velocity C F will be added one degree more, by which means will be produced the velocity E H, triple that of the firſt, and ſo of the reſt: ſo that during the whole time A B, the body will have acquired the velocity B K. After this, taking the diviſions of the line at pleaſure; for example, the diviſions A C, C E, &c. for the times; the ſpaces run through during thoſe times, will be as the areas or rectangles C D, E F, &c. So that the ſpace deſcribed by the moving body, during the whole time A B, will be equal to all the rectangles; that is to ſay, to the whole intended ſpace ACEGBKLHFD.

Thus it will happen if the increments of velocity be produced, as we may ſay, all at once, at the end of certain portions of finite time; for inſtance, at C, at E, &c. ſo that the degree of motion remains the ſame to the inſtant that a new acceleration takes place. By imagining ſhorter diviſions of time, for example, but half ſo long as the former, the indentures of the figure will be proportionably more contracted, and it will approach near unto a triangle: and, if they be taken infinitely ſmall; that is, if increments of the velocity be ſuppoſed to be acquired continually, and at each indiviſible particle of time, which is really the caſe, the rectangles ſo ſucceſſively produced will form a true triangle, as ABE; (plate I. *fig.* 7) the whole time AB conſiſting of minute portions of times, A 1, A 2, A 3, &c. and the area of the triangle ABE, of all the minute ſurfaces, or minute trapeziums, which anſwer to the diviſions of the times, the area of the whole triangle, expreſſing the ſpace run through during the time AB: or the triangles ABE, A 1 *f* being ſimilar, their areas are to each other as the ſquare of their homologous ſides AB, A 1, &c. and conſequently the ſpaces gone through, are to each other as the ſquares of the times.

Whence alſo may be deduced this great law of acceleration: *That a body deſcending with an uniformly accelerated motion, deſcribes in the whole time of its deſcent a ſpace which is exactly the half of that which it would deſcribe uniformly in the ſame time with the velocity it acquires at the end of its fall.* For, as we have already ſhewn, the whole ſpace which the falling body has run through in the time AB, will be repreſented by the triangle ABE, and the ſpace that body would run through uniformly in the ſame time, with the velocity BE, will be repreſented by the rectangle ABEF. But it is well known that the triangle is exactly equal to half the rectangle: ſo that the ſpace run through will be the half of that which the body would deſcribe uniformly in the ſame time with the velocity acquired at the end of its fall.

We may therefore conclude: 1ſt, That the ſpace which would be uniformly deſcribed in half the time AB, with the ultimately acquired velocity BE, is equal to that which has been actually run through by the falling body during the whole time AB.

2d. If the falling body deſcribes any given ſpace, or length, in a given time, in twice that time it will deſcribe four times as much; in thrice that time, nine times as much, &c. In a word, if the times are in proportion to each other, as the ſeries 1, 2, 3, 4, &c. the ſpaces run through will be as the ſquares of theſe numbers; that is, as 1, 4, 9, 16, &c. that is, if a body deſcribes, for example, 16 feet in the firſt ſecond of its fall, in the two firſt ſeconds taken together it will deſcribe four times 16 feet, nine times 16 feet in the three firſt ſeconds taken together, and ſo on.

3d. The ſpaces deſcribed by falling bodies, in a ſeries of equal inſtants, or intervals of time, will be as the odd numbers 1, 3, 5, 7, 9, &c. that is, the body which has run through 16 feet in the firſt ſecond, will in the next ſecond run through 48 feet, in the third ſecond 80 feet, &c. And, ſince the velocities acquired in falling are as the times, the ſpaces will be likewiſe as the ſquares of the velocities, and the times, and the velocities, in the ſubduplicate ratios of the ſpaces.

The motion of an aſcending body, or of one that is impelled upwards, is diminiſhed or retarded by the ſame principle of gravity, acting in a contrary direction, after the ſame manner that a falling body is accelerated.

A body projected upwards, aſcends until it has loſt all its motion, which it does in the ſame interval of time that the ſame body would have taken up in acquiring by falling, a velocity equal to that with which the falling body began to be projected upwards: and conſequently the heights to which bodies projected upwards, with different velocities, arrive, are to each other as the ſquare of thoſe velocities.

ACCELERATED *Motion of Bodies upon inclined Planes,* in mechanics. Let two equal bodies deſcend by the force of gravity, from the point A, (plate I. *fig.* 8.) the one along the line AB, and the other along the line AC; when they are come to the points B, C, they will be equally near to the earth's center: therefore the force with which they are impelled, as they are both directed towards the earth's center, will be equal. But the intenſities of equal forces are reciprocally as the ſpaces gone through; and therefore, here, the intenſity of the force by which the body is impelled along the inclined plane, is to the intenſity by which it is impelled directly towards the center of the earth, as A to B. Therefore, a body incumbent on an inclined plane, loſes part of its gravity, and the weight acquired to ſuſtain it, is to the weight of the body, as AC, the height of the plane, to AB, the length of the ſame. As the force by which a body is made to deſcend along an inclined plane ariſes from gravity, it is of the ſame nature with it, and therefore that force every moment, and in all parts of it, is equal; conſequently the motion of a body freely deſcending along an inclined plane, is analogous to that of a body freely falling; and what has been ſaid of the latter holds good here, and conſequently the motion is equally accelerated in equal times.

The forces by which two bodies deſcend, one of which falls freely, and the other runs down an inclined plane, if they begin to fall at the ſame inſtant, are ever to one another in the ſame ratio as at the beginning of the fall; wherefore the effects of thoſe forces, that is, the ſpaces gone through in the ſame time, are in the ſame ratio, namely, that of the length of the plane to its perpendicular height.

In the plane AB, the ſpace gone through by a body, whilſt another falls freely down the height of the plane AC, (plate I. *fig.* 9.) is determined by drawing CG perpendicular to AB; for then the length of the plane AB, is to its height AC, as AC to AG. If a circle be deſcribed with the diameter AC, the point G will be in the periphery of the circle; becauſe an angle in a ſemicircle, as AGC, is always a right one; and therefore a point, as G, taken in any inclination of the plane, will always be in the periphery of the ſaid circle. Whence it follows, that all the chords, as AG, are gone through by bodies running down them, in the time that a falling body would freely deſcend through the diameter AC, are equal. Through the point C there can be no chord drawn, as HC, but a chord A*g* may be parallel to it (that is equally inclined) and equal; therefore, in a ſemicircle, as AHC, whether a body falls freely along the diameter AC, or whether it falls along any chord as HC, it will in the ſame time arrive at the loweſt point C, of the ſemicircle. The time of the fall along the whole plane AB, may be compared with the time of the deſcent along the height AC; which, for that time, is equal to the time of the fall along AG, and ſo the ſquares of thoſe times are to one another, as AB to AG: but AB is to AC, as AC to AG; therefore the ſquares of the lines AB and AC, are to one another, as the times of the fall along AB and AG, or AC; that is, the times, in that caſe, are as the ſpaces gone through.

In the ſame caſe, the velocities at the end of the deſcent are equal; for, after equal times, when the bodies are at G and C, the velocities are in the ſame ratio as in the beginning of the fall, that is, as the forces by which the bodies are impelled, or as AC to AB. When the body deſcends from G to B, the velocity increaſes as the time; and the velocity at G is to the velocity at B, as AB to AB; therefore the velocities at B and C have the ſame ratio to the velocity at G, and ſo are equal. Hence it appears, that a body acquires the ſame velocity in falling from a certain height, whether it falls directly down, or along an inclined plane; and, ſince the angle of inclination cauſes no alteration, a body may run down ſeveral planes differently inclined, and even along a curve, which may be conſidered as made up of innumerable planes differently inclined; and the celerity acquired will always be the ſame when the height is equal. Upon this foundation the whole doctrine of pendulums is ſuperſtructed. See PENDULUM.

ACCELERATED *Motion of Pendulums.* See PENDULUM.

ACCELERATED *Motion of Projectiles.* See PROJECTILES.

Accelerated *Motion of compreſſed Bodies.* See Compreſſion and Elaſticity.

Acceleration, in philoſophy, implies an increaſe of velocity in the motion of a body; it is oppoſed to retardation, by which term is underſtood a diminution of velocity. See Motion, Velocity, and Retardation.

Acceleration, in aſtronomy, is the time whereby a fixed ſtar in one diurnal revolution anticipates the mean revolution of the ſun, being 3′, 56″, in one day.

ACCELERATIVE *Quantity of Centripetal Force*, in philoſophy, is the meaſure of the ſame, proportional to the velocity which it generates in a given time. If the central force be not conſidered as reſiding in the center, but at any diſtance from it, we may conceive ſpherical ſurfaces at various diſtances from the center, whoſe common center is T, (plate I. *fig.* 10.) and the central forces conſidered at thoſe diſtances, or ſpherical ſurfaces, is called the accelerative force, the quantity whereof will be proportional to the velocity which it generates in a conſtant and given time, in every one of the elements of the matter, which are equidiſtant from the center: for, ſuppoſing ſuch conſtant force continually to exert itſelf on the elements of the matter, it will be greater in proportion to the degree of velocity generated in a given time: ſo that if a double velocity be generated in an equal time, the force will likewiſe be double, ſince that velocity is the full effect of ſuch force. If the velocity generated by the accelerative force remains conſtant, the force will be in the inverſe ratio of the time wherein the velocity is generated; for, if the ſame velocity be produced in a ſubduple time, the force will be doubled: wherefore, if whilſt the force continues conſtant, the velocity and the time are varied, the accelerative force will be a ratio compounded of the direct ratio of the generated velocity, and of the reciprocal ratio of the time. If then the accelerative force be called G, the acquired velocity V, and the time in which it is acquired T; G will be $= \frac{V}{T}$, and $G \times T = V$, and $T = \frac{V}{G}$. Now, notwithſtanding the accelerative force varies, its meaſure is ever the ſame, provided the velocity be conſidered in a naſcent ſtate, or as generated in a very minute portion of time at the beginning of the motion; for then the force acts uniformly.

If any force be diffuſed by diverging rays, in a non-reſiſting medium, the accelerative force decreaſes in the duplicate ratio of the diſtances from the center: for ſince the force is, by ſuppoſition, propagated in a non-reſiſting medium, no ray is intercepted, nor the force of any of them diminiſhed, and conſequently the rays, which at the diſtance T L were propagated through the hemiſphere deſcribed by the ſemicircle P L C, at the diſtance T K, are propagated through the hemiſphere deſcribed by the ſemicircle E K H. Now the accelerative force is as the denſity of the rays, and the denſity of the rays is reciprocally as the ſurfaces of the hemiſpheres deſcribed by the ſemicircles: for the denſity of the rays is as the ſum or number of them divided by the ſurface which they occupy, ſuch ſum being as the maſs, and the occupied ſurface as the volume: but ſince, by ſuppoſition, the ſame number of rays is diffuſed over both hemiſpheres, their denſity will be in the inverſe ratio of the ſurfaces deſcribed at any diſtances from the center, and thoſe ſurfaces are in the duplicate ratio of the diſtances from the center; therefore the accelerative force is alſo in the duplicate ratio of the diſtances from the center reciprocally. From the demonſtration, it appears, that this theorem excludes all reſiſtance of the medium; wherefore, in phyſical matters, ſuch reſiſtance muſt be taken into the computus. Furthermore, this theory of forces or qualities propagated from a center, may be rendered more univerſal, by ſuppoſing the force to be variouſly propagated in the ſeveral rays, or even to be diffuſed along curve lines. See Centripetal Force.

ACCELERATORES *Urinæ*, in anatomy, two muſcles of the penis, whoſe principal office is to expedite the diſcharge of the urine and ſemen.

Authors have been miſtaken in aſſigning the origination of theſe muſcles, either to the ſphincter anis, or tubercles of the oſſa iſchii. They ariſe fleſhy from the ſuperior part of the urethra, as it paſſes under the oſſa pubis, and encompaſſing the external part of the bulb of its cavernous body, both muſcles meet on the inferior part, correſponding with the ſeam of the ſkin in the perinæum, and continue ſo united for the ſpace of about ſix inches; after which they ſeparate from each other, and aſcend to their inſertions on each ſide of the corpora cavernoſa penis.

Beſides the uſe commonly aſcribed to theſe muſcles, in compreſſing the urethra in the diſcharge of the urine, and promoting the ejaculation of the ſemen (which action is chiefly performed by the laſt deſcribed part of them embracing the urethra, as they paſs to their inſertions on each ſide the cavernous bodies of the penis); they alſo aſſiſt the erectores penis in their erection, by driving the blood contained in the bulb of the cavernous body of the urethra towards the glands in greater quantities, whereby it becomes diſtended, the veins, which carry the refluent blood from the corpus cavernoſum urethra, at that time being alſo compreſſed by the ſwelling of theſe muſcles. *Cooper.*

ACCENSI, in antiquity, were officers attending the Roman magiſtrates; their buſineſs was to ſummon the people to the public aſſemblies: they were alſo to aſſiſt the pretor when he ſat on the bench, and to give him notice every three hours what it was o'clock.

The word is Latin, and compounded of *ad*, and *cenſeo*, to reckon.

Accensi, in the Roman armies, were, according to Feſtus, ſupernumerary ſoldiers, whoſe office it was to attend their principals, and ſupply the places of thoſe who were killed or wounded. Livy mentions them as irregular troops, who were but little eſteemed. Salmaſius tells us, they were taken out of the fifth claſs of the poor citizens at Rome.

ACCENSION, in philoſophy, the act of kindling, or ſetting a body on fire.

The word is Latin, *accenſeo*, and compounded of *ad*, and *candeo*, to ſhine.

ACCENT, an inflexion of the voice, giving to each ſyllable of a word its proper pitch with regard to height or lowneſs.

The word is Latin, *accentus*, compounded of *ad*, to, and *cano*, to ſing.

Accent, in grammar, is a certain mark or character placed over a ſyllable, to direct the manner of its pronunciation, and regulate the inflection of the voice in reading. We generally reckon three grammatical accents, viz. the acute, the grave, and the circumflex.

The Greeks ſeem to have been the firſt who introduced the uſe of accents in writing. The author of *La Methode Greque*, p. 546, obſerves, that the right pronunciation of the Greek language, being natural to the Greeks, it was needleſs for them to mark it by accents, in their writings: ſo that, according to all appearance, they only began to make uſe of them ſo low as the time in which the Romans, being curious to learn the Greek tongue, ſent their children to ſtudy at Athens, thinking thereby to fix the pronunciation, and to facilitate it to ſtrangers, which happened, as the ſame author obſerves, a little before Cicero's time.

As to other matters, the only object of theſe accents of the Greeks were the inflections of the voice, ſo far as it may be either raiſed or lowered.

The acute accent, which was written from right to left, [´] ſhewed, that the voice ought to be raiſed in pronouncing that vowel on which it was marked. The grave accent, which was wrote thus [`] on the contrary, denoted that the voice ſhould be lowered. The circumflex accent is compounded of the acute and grave, though in length of time the tranſcribers rounded it after this manner [˜]; but it is only uſed in the Greek. This accent was deſigned to give us to underſtand, that, after having firſt raiſed the voice, it ſhould be lowered upon the ſame ſyllable.

The Latins have made the ſame uſe of theſe three accents. That elevation and ſinking of the voice were more ſenſible among the ancients than among us, becauſe their pronunciation was more elevated and tuneful. However, we likewiſe have a riſing and lowering of the voice in our manner of ſpeaking, and that independently of the other words of the phraſe ; ſo that the ſyllables of our words are raiſed or ſunk, according to the proſodic or tonic accent, independent of the pathetic, i. e. of the tone that paſſion and ſentiment gives to the whole phraſe ; for it is the nature of every voice, ſays the author of *La Methode Greque*, p. 551, to have ſome elevation, which keeps up the pronunciation ; and this elevation is afterwards moderated and diminiſhed, and is not laid upon the ſucceeding ſyllables.

This proſodic accent, which conſiſts only in the raiſing or ſinking of the voice in certain ſyllables, ought to be diſtinguiſhed from the pathetic tone, or the tone of the ſentiment.

Further, it is not cuſtomary with us to denote this elevation or ſinking of the voice by any ſigns or accents in our writing ; our pronunciation is leſs kept up, and has leſs harmonious modulation in it than that of the ancients, and conſequently the modification, or tone of voice ſpoken of here, is leſs perceivable : habit ſtill augments the difficulty of unravelling theſe nice differences. The ancients pronounced, at leaſt their verſes, in ſuch a manner as enabled them to meaſure the length of ſyllables, by beating with their feet. *Adſuetam moram, pollicis ſonor vel plauſu pedis, diſcriminare, qui docent artem, ſolent*, (Terentianus Maurus de metris ſub. med.) which we cannot do but by ſinging. In a word, in all kinds of oratorical accents, whether in interrogating, in admiring, in paſſion, &c. the ſyllables which precede our *s* are ſuſtained and elevated in the ſame manner as they are in common diſcourſe.

This difference between the pronunciation of the ancients and ours, appears to be the true reaſon why, though we have a quantity as they had, yet the difference of our long and ſhort quantities not being equally ſenſible in all our words, our verſes are only formed by the harmony which reſults from the number of ſyllables : whereas the Greek and Latin verſes draw their harmony from the number of feet adapted by certain combinations of long and ſhort ſyllables.

The dactyle, iambic, and other feet, enter in common diſcourſe, ſays Cicero, and the hearer eaſily knows them ; *Eos facile agnoſcit auditor*. Cic. Orat. n. lvi. "If in our theatres, ſays he, an actor pronounces a ſyllable ſhort or long, or with a grave or acute tone, otherwiſe than as it ought to be pronounced, all the people cry out againſt it. However, adds he, the people have not ſtudied the rule of our proſodia, and only feel themſelves offended by the actor's pronunciation ; but cannot explain how, or in what manner : in this particular, there is no other rule but the diſcerning it by ear ; and with that help only, which cuſtom and habit has given, they know the long and ſhort, and diſtinguiſh the grave from the acute."

ACCENT, in rhetoric, implies a particular manner of expreſſion, and gives either a good or bad ſenſe to the words, according to the intention of the ſpeaker.

ACCENT alſo implies a certain inflection of the voice ; or a peculiar tone and manner of pronunciation, contracted from the country, or province, where a perſon was bred.

ACCENT, in muſic, is a modulation of the voice to expreſs a paſſion. See MUSIC.

ACCEPTANCE, in a general ſenſe, implies the conſent of the perſon who accepts or receives.

The word is formed from the Latin *acceptio*, which is compounded of *ab*, from, and *capio*, to receive.

ACCEPTANCE, in common law, is the tacitly agreeing to ſome act which another has already done, and which, without ſuch acceptance, would have been rendered abortive.

ACCEPTANCE, in commerce, is the ſigning or ſubſcribing a bill of exchange, by which the acceptor obliges himſelf to pay the contents of the bill.

We ſhould therefore be careful not to accept any bills that we have no effects in hand to anſwer, or that we are not ſure will be remitted within the time ; becauſe, when a bill is once accepted, the acceptor becomes the principal debtor, and the bill muſt be abſolutely paid when it becomes due, otherwiſe the acceptor is liable to be ſued for the default of payment. It is uſual to leave bills of exchange with thoſe upon whom they are drawn, for acceptance. But the authors who have wrote upon commerce, obſerve, that ſuch a cuſtom is dangerous, more eſpecially when a bill is indorſed for acquittance, and is not yet accepted, as it may happen ſometimes ; in which caſe the bill ſhould not, upon any account whatſoever, be left with the perſon upon whom it is drawn ; becauſe, if he was a perſon of bad credit, he might make a bad uſe of it. However, if the perſon with whom a bill of exchange hath been left for acceptance, will keep it in his hands under any pretence whatſoever, the difficulty which he makes of returning it, is tantamount to an acceptance, and he will be obliged to pay the contents.

Bills payable at ſight are not accepted, becauſe they muſt either be paid when preſented, or elſe proteſted for want of payment.

The acceptance of bills payable at a fixed day, at uſance, or double uſance, &c. needs not be dated ; becauſe the time is reckoned from the date of the bill : but it is neceſſary to date the acceptance of bills payable at a certain number of days after ſight, becauſe the time does not begin to run till the next day after that acceptance. This kind of acceptance is made thus : *Accepted ſuch a day and year*, and ſigned.

In general, he to whom a bill of exchange is made payable ought to demand the acceptance of the perſon on whom it is drawn, and that in the full extent of the terms of the bill, and on refuſal of acceptance to return it with proteſt : this he ought to do for his own ſecurity, as well as for that of the drawer. Thus, if the bearer of a bill conſents to an acceptance at twenty days ſight, inſtead of eight days expreſſed in the bill, he runs the riſk of the twelve days prolongation ; ſo that he can have no recourſe againſt the drawer, ſhould the acceptor break in that time. Again, if a bill be drawn for three thouſand pounds, and the bearer agrees to take an acceptance for two only, and ſhould receive no more than that ſum, the remaining thouſand would be at the hazard of the bearer, as well as in the former caſe.

If therefore a bill be only accepted in part, or for a longer time than that expreſſed in it, the bearer ought to proteſt it, at leaſt for the ſum not accepted.

Again, if the acceptor breaks or refuſes to make payment when the bill becomes due, it is neceſſary to get the bill immediately proteſted by a public notary, to be ſent along with the proteſt to the remitter, to procure ſatisfaction from the drawer.

By ſtatute, inland bills of exchange muſt be accepted by ſigning or endorſing in writing, and proteſted for refuſal of ſuch acceptance, otherwiſe the drawer is not liable to coſts ; it muſt likewiſe be returned to the drawer within fourteen days. However, ſuch proteſt is not neceſſary, unleſs the value be acknowledged in the bill to be received, and unleſs the bill be drawn for twenty pounds or upwards.

A bill drawn on two jointly muſt have a joint acceptance, otherwiſe be proteſted ; but if on two or either of them, the acceptance of one is ſufficient.

ACCEPTATION, in grammar, is the ſignification or ſenſe wherein a word is taken and received. Moſt words in every language yet known, have ſeveral acceptations.

ACCEPTILLATION, in the civil law, implies an acquittance given by a creditor to a debtor, without receiving any money.

ACCEPTOR, the perſon who accepts a bill of exchange.

ACCESS, in a general ſenſe, implies the approach of one thing towards another : but, in a more particular acceptation, it ſignifies the permiſſion or leave to come near a perſon or thing.

The word is Latin, *acceſſus*, and compounded of *ad*, to, and *cedo*, to ſucceed, or approach.

ACCESS, among phyſicians, is the beginning of a paroxyſm, or fit of an intermitting diſeaſe.

ACCESSIBLE, ſomething that may be approached, or to which acceſs may be had.

ACCESSIBLE *Altitude* or *Height*. See *Acceſſible* ALTITUDE.

ACCESSIBLE *Diſtance*. See DISTANCE.

ACCESSION implies, in a general ſenſe, the act of approaching, or going to a place, perſon, or thing. But, in a more reſtrained acceptation, it ſignifies the act whereby a thing is joined or united to ſomething that previouſly exiſted.

Accession is alſo uſed to ſignify a prince's ſucceſſion to the throne; and likewiſe the act of engaging and becoming a party in a treaty before concluded between other powers.

Accession, in the healing art, implies the beginning of the fit or paroxyſm of an intermitting fever.

ACCESSORIUS, a name given to a particular nerve by Dr. Willis. It belongs to the eighth pair, and ariſes by ſeveral filaments from both ſides of the medulla ſpinalis of the neck.

ACCESSORY, or Accessary, in a general ſenſe, implies whatever accedes, or is added to another and more principal object.

Accessory, or Accessary, in law, ſignifies a perſon guilty of a felonious offence, not principally, but by participation, as by command, advice, or concealment.

Acceſſories are of two kinds, viz. acceſſories before the fact, and acceſſories after it. An acceſſory before the fact is he that, being ſent at the time of the felony committed, procures, counſels, commands, or abets another to commit a felony. This is an offence greater than the acceſſory after; and therefore, in many caſes, clergy is taken away from acceſſories before it, which yet is not taken away from acceſſories after, as in petit treaſon, murder, robbery, and wilful burning. Acceſſories after the fact is, where a perſon, knowing the felony to be committed by another, receives, relieves, comforts, or aſſiſts the felon.

ACCIDENT, ſomething produced caſually, without any previous intention in the agent.

Accident, in metaphyſics, ſomething additional or ſuperadded to an object, not eſſentially belonging to it, and without which the object can ſubſiſt.

Accident, in heraldry, is an additional note or mark in a coat of arms, which may be either omitted or retained, without altering the eſſence of the armour.

Accident, among grammarians, implies a property attached to a word, without entering into its eſſential definition; for every word, notwithſtanding its ſignification, will be either primitive, derivative, ſimple, or compound, which are the accidents of words.

A word is ſaid to be primitive, when it is taken from no other word in the language in which it is uſed: thus *heaven*, *king*, *good*, are primitive words. It is ſaid to be derivative, when it is taken from ſome other word: thus *heavenly*, *kingdom*, *goodneſs*, *&c.* are derivatives. A ſimple word is eaſily diſtinguiſhed from a compound: thus *juſt*, *juſtice*, are ſimple words; *unjuſt*, *injuſtice*, are compound: *res* is a ſimple word as well as *publica*; but *reſpublica* is a compound.

Beſides theſe accidents, which are common to all ſorts of words, each particular ſpecies has its accidents: thus the accidents of the noun ſubſtantive are the gender, declenſion, and number: and the adjective has another accident, namely, the compariſon.

Accident, in logic, is when we join a confuſed and indeterminate idea of ſubſtance with a diſtinct idea of ſome mode; becauſe it is then capable of repreſenting every thing to which that mode can belong. Thus the idea of prudent will comprehend a prudent man, a prudent action, &c. and the idea of round, all round bodies: this forms the fifth univerſal, and is called accident, becauſe not eſſential to the thing to which it is attributed. But it ſhould be obſerved, that when we conſider two ſubſtances together, we may conſider one of them as the mode of the other: thus a dreſſed man may be conſidered as a whole, compoſed of the man and his clothes; but to be dreſſed, in reſpect to that man, is only a mode, under which we conſider him, notwithſtanding the different parts of his habit may be ſubſtances.

Accident, among phyſicians, ſignifies a revolution, occaſioned by ſome new cauſe, which adds ſtrength to the diſeaſe already exiſting. The moſt celebrated practitioners in the healing art recommend the utmoſt attention to the violence of accidents, becauſe their continuance may augment the diſtemper to ſuch a degree as to render it incurable.

ACCIDENTAL, in a general ſenſe, implies ſomething that happens by accident, or that is not eſſential to its ſubject.

Accidental, in philoſophy, is applied to that effect which flows from ſome cauſe intervening by accident, without being ſubject, or at leaſt without any appearance of being ſubject, to general laws, or regular returns. In this ſenſe *accidental* is oppoſed to *conſtant* and *principal*. Thus the ſun's place is, with reſpect to the earth, the conſtant and principal cauſe of the heat in ſummer, and the cold in winter; whereas winds, ſnows, and rains, are the accidental cauſes, which often alter and modify the action of the principal cauſe.

Accidental *Point*, in perſpective, is that point in the horizontal line where the projections of two lines parallel to each other meet the perſpective plane.

ACCIPENSER, in natural hiſtory, a genus of fiſhes, whoſe mouths are tubular and without teeth. They have only a ſingle hole or aperture of the gills on each ſide; the body is oblong, and generally furniſhed with ſeven fins. There are only two ſpecies of this fiſh, namely, the ſturgeon and huſo, or iſinglaſs fiſh. See Sturgeon and Isinglass.

ACCIPITER, in mythology, the name of a genus of birds, whoſe diſtinguiſhing characteriſtic is a crooked or hooked bill. This genus is ſubdivided into three claſſes, the parrot, the owl, and the hawk kinds.

Among the Romans, the term *accipiter* ſignified a hawk, and which, from its being very carnivorous, they conſidered as a bird of bad omen.

> *Odimus accipitrem quia ſemper vivit in armis.* Ovid.

Pliny, however, tells us, that in ſome caſes, particularly in marriage, it was eſteemed a bird of good omen; becauſe it never eats the hearts of other birds; intimating thereby, that no differences, in a married ſtate, ought to reach the heart.

The accipiter was worſhipped as a divinity by the inhabitants of Tentyra, an iſland in the Nile, being conſidered by them as the image of the ſun; and hence we find that luminary repreſented in hieroglyphics, under the figure of a hawk.

ACCISMUS, in antiquity, implies a feigned refuſal of what a perſon earneſtly deſires.

Accismus, in rhetoric, is a ſpecies of irony. See Irony.

ACCLAMATION, a token of joy or applauſe, whereby the public teſtify their eſteem and approbation.

The word is Latin, *acclamatio*, and compounded of *ad*, to, or at, and *clamo*, to ſhout, or cry aloud.

The forms of acclamation, among the ancients, were different among different nations. The Hebrews uſed to cry *Hoſannah*, and the Greeks *αγαθη τυχη*, good fortune. Herodotus mentions ſome magiſtrates at Athens who were elected by acclamation, though it was not indicated by ſhouts, but by holding up of hands. The Barbarians teſtified their approbation by a confuſed noiſe, or claſhing of their arms. Among the Romans there were three different kinds of acclamations, that of the people, that of the ſenate, and that of the aſſemblies of the learned.

The acclamations of the people were ſhewn at the public entries of emperors and generals; at the ſhews given by the magiſtrates; and at the triumphs of conquerors. Theſe acclamations were originally nothing more than the confuſed ſhouts of the multitude tranſported with joy; the ſimple undiſguiſed expreſſions of public approbation. But, under the emperors, this impetuous motion, to which the people abandoned themſelves as it were by enthuſiaſm, became an art, and a ſtudied harmony; a muſician ſet the tune, and the people giving two chears, alternately repeated the form of the acclamation. The moſt common forms were *feliciter*, *longiorem vitam*, *annos felices*: thoſe of triumph were verſes in praiſe of the conqueror, the ſoldiers and people crying out at certain intervals, *io triumphe*.

The acclamations of the ſenate, though more ſerious, had the ſame end, that of honouring, and often flattering, the prince. The forms generally uſed to teſtify their approbation of his propoſitions, were, *omnes*, *omnes*, *æquum eſt*, *juſtum eſt*.

It was cuſtomary for men of letters to recite their compoſitions in the Capitol, or ſome temple, before a numerous aſſembly; and the acclamations were there given nearly in the ſame manner as at the public ſhews.

ACCLIVIS, in anatomy, is the name by which ſome writers call the obliquus aſcendens.

ACCLIVITY, the ſlope or aſcent of a line or plane, conſidered in its aſcending direction.

The word is Latin, and compounded of *ad*, and *clivus*, a ſlope.

Some writers on fortification have uſed the term acclivity as ſynonimous with talus; but the latter properly ſignifies the ſlope in general, whether it be conſidered as aſcending or deſcending.

ACCLOYED, in farriery, ſignifies pricked. Thus a horſe's foot, when pricked with a nail in ſhoeing, is ſaid to be accloyed.

ACCOMMODATION, among divines, implies the application of what is ſaid of one perſon or thing to another. Thus the words of Iſaiah, delivered to the Jews of his time, are, by St. Paul, accommodated to that people who were contemporaries with the apoſtle.

The word is Latin, and compounded of *ad*, to, and *commodius*, commodious.

Accommodation, in philoſophy, is the application of one thing to another by analogy.

Accommodation, in law, ſignifies an amicable agreement between two contending parties.

ACCOMPANYMENT, in muſic, implies the inſtruments that accompany a voice to render the melody more agreeable.

The manner of accompanying depends more upon practice and taſte, than upon any rules that can be given.

Accompanyments, in painting, are the objects added either by way of ornament or probability. Thus dogs, guns, and game, are the proper accompanyments of a hunting piece, and tend greatly to ornament the picture.

ACCOMPLICE, in law, is a perſon who was privy to, or aſſiſted in, the perpetration of ſome crime. See Accessory.

The word is compounded of the Latin *ad*, to, *con*, together, and *plico*, to fold.

ACCOMPLISHMENT, in a general ſenſe, ſignifies the execution and ſucceſs of a thing we before propoſed to ourſelves.

The word is compounded of the Latin *ad*, and *compleo*, to finiſh, or fulfil.

The accompliſhment of the prophecies of the Old Teſtament, in the perſon of Our Saviour, very clearly ſhews that he was the Meſſiah.

The accompliſhment of a prophecy may be done two ways, either directly, or by accommodation; for one and the ſame prophecy may have ſeveral accompliſhments at different times: as, for inſtance, that of Our Saviour, touching the deſtruction of Jeruſalem, which muſt have a ſecond accompliſhment in the times which ſhall immediately precede the laſt judgment.

This principle is not, however, univerſal, and may even be dangerous in many reſpects, by falling into the ſyſtem of Grotius upon the accompliſhment of prophecies. We muſt therefore ſay, that the accompliſhment, or the literal ſenſe of the prophecy, is its direct accompliſhment, and that the figurative ſenſe of a prophecy is its accompliſhment by accommodation: this implies no more than that the prophecies have been literally accompliſhed in the perſon of Jeſus Chriſt, whom they prove to be the Meſſiah. As to the accompliſhment of accommodation, it is proved no further than it is contained, or clearly pointed out, in the Scriptures, or conſtantly delivered down to us by tradition; for we are not ignorant how far fanaticiſm, and the irregularity of imagination, may go in this matter, when we would interpret the ſenſe of prophecies, and fix the accompliſhment of them according to our own fancies. Thoſe who are perſuaded that the human mind is not of itſelf more capable of fixing the accompliſhment of a prophecy, than of predicting the future in a ſure and circumſtantial manner, ſhould always obſerve this rule, *omnis prophetia ſcripturæ propria interpretatione non fit.*

We ſhall, however, add, that there are prophecies partly accompliſhed in one ſenſe, and in reſpect of a certain object; and fully accompliſhed in another: ſuch are the predictions of the deſtruction of Jeruſalem, and ſome of thoſe in the Apocalypſe.

ACCOMPT. See Account.

ACCORD, in muſic, the ſame with concord. See Concord.

Accord, in law, implies an accommodation between contending parties, by means of an offer made by the one, and accepted by the other.

Accord, in painting, ſignifies the harmony that reigns among the lights and ſhades of a picture.

ACCORNED, in heraldry, is the term applied to every animal borne in an eſcutcheon, when its horns are of different colours from thoſe of the real animal; when it is ſaid to be accorned.

ACCOUNT, or Accompt, in arithmetic, a computation of the number of certain things, whether they relate to time, weight, meaſure, money, &c.

The word is compounded of the Latin *ad*, to, and *computus*, computation.

Account, is alſo uſed to ſignify the books in which merchants, &c. enter all their buſineſs. See Book-keeping.

Account *in company* is an account kept by traders in partnerſhip, containing all the articles relating to their joint trade.

Account, in law, ſignifies a writ or action which lies againſt a bailiff, or receiver, who refuſes to give a proper account to another appointed for that purpoſe.

The proceedings upon this action being difficult, dilatory, and expenſive, it is now ſeldom uſed, eſpecially if the party has any other remedy, as debt, covenant, caſe, or other action; or if the demand be of conſequence, and the matter of an intricate nature; for, in ſuch caſes, it is more adviſeable to have recourſe to a court of equity, where matters of account are more commodiouſly adjuſted, and more advantageouſly determined with regard to both parties; the plaintiff being in that court entitled to a diſcovery of books, papers, and the defendant's oath: and on the other hand, the defendant allowed to diſcount the ſums paid or expended by him, and all reaſonable allowances, and to diſcharge himſelf of ſums under forty ſhillings by his own oath, if by anſwer or other writing he charges himſelf with ſuch. He is likewiſe entitled, after the account is ſettled, to a decree in his favour, if any thing appears to be due to him on the balance.

Chamber of Accounts, the name of a ſovereign court in France, anſwering nearly to our Exchequer.

ACCOUNTANT, or Accomptant, a perſon appointed to keep the accounts of a company, office, &c. It alſo ſignifies one ſkilled in the nature of accounts, or who makes the ſtudy and practice of accounts his buſineſs.

Accountant-general is an officer in the Court of Chancery, appointed by act of parliament to receive all monies lodged in court, and convey the ſame to the bank of England for the better ſecurity.

ACCRETION, in natural hiſtory and philoſophy, is the increaſe or augmentation of a body by the addition of new parts. See Nutrition.

The word is Latin, *accretio*, and compounded of *ad*, to, and *creſco*, to grow.

Accretion, in the civil law, implies the property of a vague or unoccupied thing, acquired by its adhering to or following another thing already occupied.

ACCUSATION, in law, ſignifies the act of accuſing, or the charge brought againſt any one for a crime.

The word is Latin, *accuſatio*, and compounded of *ad*, to, and *cauſor*, to blame.

By Magna Charta, no man ſhall be impriſoned or condemned on any accuſation, without trial by his peers, or the law. None ſhall be vexed with any accuſation, but according to the law of the land: and no man may be moleſted by petition to the king, &c. unleſs it be by indictment or preſentment of lawful men, or by proceſs at common law. Promoters of ſuggeſtions are to find ſurety to purſue them, and if they do not make them good, ſhall pay damages to the party accuſed, and alſo a fine to the king. No perſon is obliged to anſwer upon oath to a queſtion whereby he may accuſe himſelf of any crime, &c.

ACCUSATIVE, in the Latin grammar, is the fourth caſe of nouns, and ſignifies the relation of the noun on which the action implied in the verb terminates; and hence, in ſuch languages as have caſes, theſe nouns have a particular termination called accuſative: as *Auguſtus vicit Antonium*, Auguſtus vanquiſhed Antony. Here *Antonium* is the noun, on which the action implied in the verb *vicit* terminates; and therefore muſt have the accuſative termination. Ovid, ſpeaking of the palace of the ſun, ſays, *Materiem ſuperabat opus.* The work ſurpaſſed the materials. Here *materiem* has the accuſative termination; becauſe it determines the action of the verb *ſuperabat*.

In the Engliſh language there are no caſes, except the genitive, the relation of the noun being ſhewn by the aſſiſtance of prepoſitions, as *of*, *to*, *from*, *&c.* By this means we are not embarraſſed with the trouble and difficulties attending other languages.

ACEPHALI, or Acephalitæ, in eccleſiaſtical hiſtory, a term applied to ſeveral ſects who refuſed to follow ſome noted leader. Thus the perſons who refuſed to follow either John of Antioch, or St. Cyril, in a diſpute that happened in the council of Epheſus, were termed *Acephali*, without a head, or leader. Such biſhops alſo as were exempt from the diſcipline and juriſdiction of their patriarch were ſtiled *Acephali*.

The word is Greek, and compounded of α, priv. and κεφαλη, a head.

ACER, in botany, the maple-tree. See Maple.

Acer *Majus*, the great maple, commonly called the ſycamore. See *Great* Maple.

ACERIA, in antiquity, an altar, erected by the Romans, near the gate of a perſon deceaſed, on which his friends daily offered incenſe till the time of his burial.

The Chineſe have ſtill a cuſtom ſimilar to this, of erecting an altar to a perſon immediately after his deceaſe, in ſome room of the houſe which is generally hung with mourning. An image, or repreſentation of the deceaſed, is laid upon the altar, and every one approaches it, bows four times, and offers oblations of perfumes.

ACETABULUM, in antiquity, a meaſure uſed by the ancients, equal to one eighth of our pint.

It ſeems to have acquired its name from a veſſel in which *acetum*, or vinegar, was brought to their tables, and probably contained about this quantity.

Acetabulum, in anatomy, a large cavity of a bone which receives another convex bone in order to admit of a circular motion in the joint thus articulated.

Thus the large cavity found in the oſſa innominata is particularly called the acetabulum, which receives the head of the femur, or thigh bone. It is formed by the juncture of the os ilium, iſchium, and pubes.

Acetabulum alſo ſignifies a kind of glandular ſubſtance, many of which are found in the placenta of ſome animals. See Cotyledon.

Acetabulum, in botany, a genus of ſea plants, whoſe leaves are ſhaped like a baſon.

ACETARY, a term uſed by Dr. Grew, for a certain part of the ſtructure of ſome fruits, on account of its ſourneſs.

ACETOSA, in botany, common ſorrel. It has a long, fibrous, yellowiſh bitter root, and long oval leaves placed alternately on the ſtalk, which is ſtriated a foot in length, and divided into ſeveral branches. The empalement of the flower is compoſed of three ſmall leaves bended backwards. The flower has three leaves, larger than thoſe of the empalement. In the center of the flower is a three cornered pointal, or piſtil, ſupporting three ſmall ſtyles, ſurrounded with ſix ſtamina. It afterwards becomes a triangular ſeed, incloſed by the petals of the flower. In ſhort, it agrees with the dock in all its characters, except in having an acid taſte. It is but a ſmall plant in the fields, but in the gardens produces large leaves. It muſt be ſown early in the ſpring, in a ſhady moiſt border; and, if the plants are afterwards removed into another ſhady border, they will produce ſtill larger leaves, and continue much longer. Sorrel is uſed in medicine to cool and quench thirſt; and the decoction of the leaves makes a uſeful drink in fevers. It is excellent againſt the ſcurvy, and in ſome cold countries they uſe a mixture of the juices of ſorrel and ſcurvy-graſs againſt this diſeaſe with ſucceſs. *Brookes's Natural Hiſt.*

Acetosa *Rotundifolia*, round-leaved or French ſorrel. This plant has the ſame character as the former, excepting the leaves, which are ſometimes almoſt round. This is the beſt ſort for kitchen uſe, and therefore is often planted in gardens. The roots are very apt to ſpread, by which means it is eaſily propagated, and muſt be planted at greater diſtances than the former, namely, a foot at leaſt. It is cooling like the former, quenches thirſt, and excites an appetite. The decoction of it is good in bilious fevers. *Brookes's Natural Hiſt.*

ACETOSE, or Acetous, an epithet applied to ſuch liquors, fruits, &c. as have a ſour taſte, or partake of the nature of vinegar.

ACETUM, vinegar. See the article Vinegar.

Acetum *diſtillatum*, diſtilled vinegar. See *diſtilled* Vinegar.

Spiritus Aceti, ſpirit of vinegar. See *Spirit* of Vinegar.

Acetum *Roſatum*, vinegar of roſes. See *Vinegar* of Roses.

Acetum *Radicatum*, a name given by the old chemiſts to what is now called tartarus regeneratus. See Tartarus *Regeneratus*.

ACHANE, a corn meaſure anciently uſed in Perſia: it was equal to forty-five Attic medini.

ACHAT, in law, implies a purchaſe or bargain. And hence probably purveyors were called *Achators*, from their making bargains.

ACHATES, in natural hiſtory, a precious ſtone generally called an agate. See Agate.

ACHE, or Ach, a ſevere pain in any part of the body, as the head ache, tooth ache, &c. See Head-Ache, Tooth-Ache, &c.

ACHERNER, in aſtronomy, a ſtar of the firſt magnitude in the ſouthern extremity of the conſtellation Eridanus. Its longitude is 11°. 48′ 20″. of Piſces, and its latitude 32°. 46′. 3″. S.

ACHILLEA, in the Linnean ſyſtem of botany, a genus of plants of the ſyngeneſia claſs, comprehending the millefolium and ptarmica of Tournefort.

ACHILLEAD, or Achilleis, the title of a famous poem, written by Statius, in which that poet intended to relate the whole life of Achilles; but was prevented by death from executing his purpoſe. The work contains only the infancy and education of the hero; and even that hiſtory is very imperfect.

This work is of the epic kind, but very deficient in the plan or fable, though Julius Scaliger has preferred Statius to all the heroic poets of Greece and Rome, Homer not excepted. It is however generally agreed, that Statius has treated his ſubject more like an hiſtorian than a poet, without confining himſelf to what conſtitutes a true epic poem. At the ſame time his diction and verſification, by ineffectually endeavouring to reach the ſublime, becomes tumid, and deviates into bombaſt. Nor is the entire hiſtory of the life of an hero a proper ſubject of an epic poem.

ACHILLES, an appellation ſometimes given to the principal argument made uſe of by each ſect of ancient philoſophers in defence of their ſyſtem.

Tendo Achilles, in anatomy, is the tendon formed by the tails of ſeveral muſcles, and inſerted into the os calcis. It has its name from the fatal wound Achilles is ſaid to have received in that part before the walls of Troy.

ACHOR, in phyſic, is a ſpecies of the herpes, and appears with a cruſted ſcab formed by a humour ſomewhat viſcid, and reſembling ichor, whence the ſore itſelf is called achor. It is occaſioned by a ſalt ſharp ſerum oozing through the ſkin.

ACHRONICAL, in aſtronomy, ſee the article Acronical.

ACID, a general name for every thing that affects the organs of taſte with a pungent ſourneſs.

Acids are the moſt ſimple of all ſaline ſubſtances with regard to their taſte; and by that particular they are chiefly known. They have alſo the property of turning all the blue and violet colours of vegetables red, which diſtinguiſhes them from all other ſalts.

The form under which acids moſt commonly appear, is that of a tranſparent liquor; though ſolidity is rather their natural ſtate. This is owing to their affinity with water; which is ſo great, that, when they contain but juſt as much of it as is neceſſary to conſtitute them ſalts, and conſequently have a ſolid form, they rapidly unite with that fluid the moment they come into contact with it: and, as the air is always loaded with moiſture and aqueous vapours, its contact alone is ſufficient to liquify acid ſalts; becauſe they unite with its humidity, imbibe it greedily, and by that means become fluid. We therefore ſay, they attract the moiſture of the air. This change of a ſalt from a ſolid to a fluid ſtate, by the ſole contact of the air, is alſo called deliquium; ſo that when a ſalt changes in this manner from a ſolid into a fluid form, it is ſaid to run *per deliquium*.

Acids in general have a great affinity with earths: that with which they moſt readily unite, is that called abſorbent earth. They ſeem to exert no action at all upon vitrifiable earths, ſuch as ſand, and ſome other kinds, at leaſt while they continue in their natural ſtate.

When an acid liquor is mixed with an abſorbent earth, for inſtance with chalk, theſe two ſubſtances inſtantly unite with ſo much impetuoſity, eſpecially if the acid liquor be thoroughly dephlegmated, that a great ebullition is immediately produced, attended with conſiderable hiſſing, heat, and vapours, which riſe the very inſtant of their conjunction.

From the combination of an acid with an abſorbent earth, there ariſes a new compound, which ſome chemiſts have called *ſal ſalſum*; becauſe the acid, by uniting with the earth, loſes its ſour taſte, and acquires another not unlike that of the common ſea-ſalt uſed in our kitchens; yet varying according to the different ſorts of acids and earths combined together. The acid at the ſame time loſes its property of turning vegetable blues and violet colours, red.

If we enquire what is become of its propenſity to unite with water, we ſhall find that the earth, which of itſelf is not ſoluble in water, hath, by its union with the acid, acquired a facility of diſſolving therein; ſo that our *ſal ſalſum* is ſoluble in water. But, on the other hand, the acid hath, by its union with the earth, loſt part of the affinity it had with water; ſo that if a *ſal ſalſum* be dried, and freed of all ſuperfluous humidity, it will remain in that dry ſolid form, inſtead of attracting the moiſture of the air, and running *per deliquium*, as the acid would do, if it were pure and unmixed with earth. This general rule, however, admits of ſome exceptions; and we ſhall have occaſion in another place to take notice of certain combinations of acids with earths, which ſtill continue to attract the moiſture of the air, though not ſo ſtrongly as a pure acid.

Univerſal or Vitriolic ACID is ſo called, becauſe it is in fact the acid which is moſt univerſally diffuſed through all nature, in waters, in the atmoſphere, and in the bowels of the earth. But it is ſeldom pure, being almoſt always combined with ſome other ſubſtance. That from which we obtain it with moſt eaſe, and in the greateſt quantity, is vitriol, a mineral which we ſhall conſider afterwards: and this is the reaſon why it is called the vitriolic acid, the name by which it is generally known. See VITRIOL.

When the vitriolic acid contains but little phlegm, yet enough to give it a fluid form, it is called oil of vitriol. See *Oil of* VITRIOL.

If the vitriolic acid contain much water, it is then called *Spirit of* VITRIOL. When it does not contain enough to render it fluid, and ſo is in a ſolid form, it is named the *Icy Oil of* VITRIOL. See each under its proper article.

When oil of vitriol highly concentrated is mixed with water, they ruſh into union with ſuch impetuoſity, that the moment they touch each other, there ariſes a hiſſing noiſe like that of red-hot iron plunged in cold water, together with a very conſiderable degree of heat proportioned to the degree in which the acid was concentrated.

If, inſtead of mixing this concentrated acid with water, you only leave it expoſed to the air for ſome time, it attracts and imbibes the moiſture. Both its bulk and its weight are increaſed by this acceſſion; and if it be under an icy form, that is, if it be concreted, the phlegm thus acquired, will ſoon reſolve it into a fluid.

The addition of water renders the vitriolic acid, and indeed all other acids, weaker in one ſenſe; that is, they leave on the tongue a much fainter taſte of acidity, and are leſs active in the ſolution of ſome particular bodies: but occaſions no change in the ſtrength of their affinities; it even, in ſome caſes, enables them to diſſolve ſeveral ſubſtances, which, when well dephlegmated, they are incapable of attacking.

The vitriolic acid, combined to the point of ſaturation with a particular abſorbent earth, the nature of which is not yet well known, forms a neutral ſalt that chryſtallizes. This ſalt is called *Alum*, and the figure of its chryſtals is that of an octahedron or ſolid of eight ſides. See ALUM.

The vitriolic acid, combined with certain earths, forms a kind of neutral ſalt called *Selenites*, which chryſtallizes in different forms, according to the nature of its earth. There are numberleſs ſprings of water impregnated with diſſolved *Selenites*; but when once this ſalt is chryſtalized, it is exceeding difficult to diſſolve it in water a ſecond time. See the article SELENITES.

If an alkali be preſented to the ſelenites, or to alum, theſe ſalts will be thereby decompoſed; that is, the acid will quit the earths, and join the alkali, with which it hath a greater affinity. And, from this conjunction of the vitriolic acid with a fixed alkali, there reſults another ſort of neutral ſalt, which is called *Arcanum duplicatum*, *Sal de duobus*, and *vitriolated Tartar*, becauſe one of the fixed alkalies moſt in uſe is called *Salt of Tartar*. See *Salt of* TARTAR.

The vitriolic acid is capable of uniting with the phlogiſton, or rather it has a greater affinity with it than with any other body: whence it follows that all compounds, of which it makes a part, may be decompoſed by means of the phlogiſton.

From the conjunction of the vitriolic acid with the phlogiſton, ariſes a compound called *Mineral Sulphur*; becauſe it is found perfectly formed in the bowels of the earth. It is alſo called ſulphur vivum, or ſimply, ſulphur. See SULPHUR.

Nitrous ACID, a particular kind of acid, which, combined with an alkaline ſalt, forms a body called Nitre. See NITRE.

It is not certainly known what conſtitutes the difference between the nitrous and the vitriolic acid, with regard to the conſtituent principles of each. The moſt probable opinion is, that the nitrous acid is no other than the vitriolic acid combined with a certain quantity of phlogiſton by the means of putrefaction. If this be fact, the phlogiſton muſt be united with the univerſal acid in another manner than it is in ſulphur, and in its volatile ſpirit; for the nitrous acid differs from them both in its properties. What increaſes the probability of this opinion, is, that the nitrous acid is found only in earths and ſtones which have been impregnated with matters ſubject to putrefaction, and which therefore muſt contain the phlogiſton; for it ſhould be obſerved, that all ſubſtances ſuſceptible of putrefaction, really contain the phlogiſton.

The nitrous acid, combined with certain abſorbent earths, ſuch as chalk, marble, boles, forms neutral ſalts which do not chryſtallize; and which, after being dried, run in the air *per deliquium*.

All thoſe neutral ſalts, which conſiſt of the nitrous acid, joined to an earth, may be decompoſed by a fixed alkali, with which the acid unites, and deſerts the earth; and from this union of the nitrous acid with a fixed alkali, reſults a new neutral ſalt, which is called *Nitre*, or *Salt-petre*. See NITRE.

The nitrous acid hath not ſo great an affinity with earths and alkalies, as the vitriolic acid hath with the ſame ſubſtances; whence it follows, that the vitriolic acid decompoſes all neutral ſalts ariſing from a combination of the nitrous acid with an earth or an alkali. The vitriolic acid expels the nitrous acid, unites with the ſubſtance which ſerved it for a baſis, and form therewith a neutral ſalt, which is either an alum, a ſelenites, or a vitriolated tartar, according to the nature of that baſis.

The nitrous acid, when thus ſeparated from its baſis by the vitriolic acid, is named *Spirit of Nitre*, or *Aqua Fortis*. If it be dephlegmated, or contain but little ſuperfluous water, it exhales in reddiſh vapours; theſe vapours, being condenſed and collected, form a liquor of a browniſh yellow, that inceſſantly emits vapours of the ſame colour, and of a pungent diſagreeable ſmell. Theſe characters have procured it the names of ſmoking ſpirit of nitre, and yellow aqua fortis. This property in the nitrous acid, of exhaling in vapours, ſhews it to be leſs fixed than the vitriolic acid; for the latter, though ever ſo thoroughly dephlegmated, never yields any vapours, nor has it any ſmell. See *Spirit of* NITRE, and AQUA *Fortis*.

Marine ACID, or the ACID *of Sea Salt*, an acid obtained from ſuch ſea-ſalt as is uſed in our kitchens.

It is not certainly known in what this acid differs from the vitriolic and the nitrous, with regard to its conſtituent parts. Several of the ableſt chymiſts, ſuch as Becher and Stahl, are of opinion that the marine acid is no other than the univerſal acid, united to a particular principle, which they call a mercurial earth; but it muſt be owned, that the truth of this opinion is ſo far from being proved by a ſufficient number of experiments, that the very exiſtence of ſuch a mercurial earth is not yet well eſtabliſhed; and therefore, that we may not exceed the bounds of our knowledge, we ſhall content ourſelves with delivering here the properties which characterize the acid in queſtion, and by which it is diſtinguiſhed from the two others already conſidered.

When it is combined with abſorbent earths, ſuch as lime and chalk, it forms a neutral ſalt that does not chryſtallize, and, when dried, attracts the moiſture of the air. If the abſorbent earth be not fully ſaturated with the marine acid, the ſalt thereby formed has the properties of a fixed alkali. The marine acid, like the reſt, hath not ſo great an affinity with earths, as with fixed alkalies.

When it is combined with the latter, it forms a neutral ſalt, which ſhoots into cubical chryſtals. This ſalt is inclined to grow moiſt in the air, and is conſequently one of thoſe which water diſſolves in equal quantities, at leaſt as to ſenſe, whether it be boiling hot or quite cold.

The affinity of this acid with alkalies and abſorbent earths is not ſo great as that of the vitriolic and nitrous acids with the ſame ſubſtances: whence it follows, that when combined therewith, it may be ſeparated from them by either of thoſe acids.

The acid of ſea-ſalt, thus diſengaged from the ſubſtance which ſerved it for a baſis, is called *Spirit of Salt*. See *Spirit of* SEA-SALT.

The acid of ſea-ſalt, like the other two, ſeems to have a greater affinity with the phlogiſton than with fixed alkalies. We are led to this opinion by a very curious operation, which gives reaſon to think that ſea-ſalt may be decompoſed by the proper application of a ſubſtance containing the phlogiſton.

From the marine acid, combined with a phlogiſton, reſults a kind of ſulphur, differing from the common ſort in many reſpects; but particularly in this property, that it takes fire of itſelf upon being expoſed to the open air. This combination is called *Phoſphorus*. See the article PHOSPHORUS.

From what has been ſaid of the union of the acid of ſea-ſalt with a fixed alkali, and of the neutral ſalt reſulting from that combination, it may be concluded that this neutral ſalt is no other than the common kitchen ſalt. But it muſt be obſerved, that the fixed alkali, which is the natural baſis of the common ſalt obtained from ſea-water, is of a ſort ſomewhat different from fixed alkalies in general, and hath certain properties peculiar to itſelf. See the article NATRON.

If the acid of ſea-ſalt be ſeparated from its baſis, by means of the vitriolic acid, it is eaſy to ſee that, when the operation is finiſhed, the ſalt we have been ſpeaking of muſt be the reſult. Glauber, a famous chymiſt, was the firſt who extracted the ſpirit of ſalt in this manner, examined the neutral ſalt reſulting from his proceſs, and, finding it to have ſome ſingular properties, called it his *Sal mirabile*, or wonderful ſalt: on this account it is ſtill called Glauber's *Sal mirabile*, or plainly Glauber's ſalt. See SAL *mirabile Glauberi*.

When the baſis of ſea-ſalt is combined with the nitrous acid to the point of ſaturation, there reſults a neutral ſalt, or a ſort of nitre, differing from the common nitre; firſt, in that it attracts the moiſture of the air pretty ſtrongly, and this makes it difficult to chryſtallize; ſecondly, in the figure of its chryſtals, which are parallelopipeds; and this has procured it the name of quadrangular nitre.

Common ſalt, or the neutral ſalt, formed by the combining the marine acid with this particular ſort of fixed alkali, has a taſte well known to every body. The figure of its chryſtals is exactly cubical. It grows moiſt in the air, and, when expoſed to the fire, it burſts before it melts into many little fragments, with a crackling noiſe; which is called the decrepitation of ſea ſalt.

That neutral ſalt mentioned above, which is formed by combining the marine acid with a common fixed alkali, and called *ſal febrifugum ſylvii*, hath alſo this property.

Vegetable ACID. See the articles TARTAR and VINEGAR.

Animal ACID. See ANALYSIS of *Animal Subſtances:*

ACIDS, in the materia medica, are ſuch medicines as are poſſeſſed of an acid quality; as vinegar, tartar, the juice of lemons, and other vegetable productions, ſpirit of vitriol, &c.

"All fermenting juices, ſays Dr. Cheyne, as acids
" plainly are, muſt be highly injurious to weak conſti-
" tutions; for, by meeting with crudities in the bowels,
" they muſt raiſe a new conflict and colluctation there,
" and ſo muſt blow up the cavities of the human body
" with acrid fumes and vapours, the great and ſore ene-
" mies to ſuch bowels." But we cannot help thinking that this cenſure is too general; and that the vinous acids ſhould have been excepted. It is indeed well known that, in the Weſt-Indies, where the violence of the heat renders it neceſſary to drink large quantities, and the want of proper liquors obliges them to drink much punch, the acid of the lemons and oranges, though in their full perfection, cauſes that nervous and mortal diſtemper, called the *dry belly ache*, as well as palſies, cramps, and convulſions. But we apprehend, that if cream of tartar was ſubſtituted inſtead of the acid of lemons and oranges, theſe terrible diſeaſes would be avoided, at leaſt as far as the acid can be ſuppoſed to cauſe them: and it ſhould be remembered that the ancient Romans were ſo fully perſuaded of the virtues of vinous acids, that the drink of their common ſoldiers was water mixed with vinegar, a compoſition which they called Poſca. Hippocrates ſays, that vinegar is refreſhing (οξος ψυκϑικον) for which reaſon it was given to reapers, and thoſe who worked in the field.

ACIDITY, that quality in bodies which renders them acid. See ACID.

ACIDULÆ, a name given to thoſe mineral waters which are ſuppoſed to be impregnated with ſome acid; an opinion which later obſervations have proved to be deſtitute of foundation. It is however ſtill uſed as an appellation of cold mineral waters, to diſtinguiſh them from thoſe that are hot. See *Medicinal* WATERS.

The word is a diminutive of *acidus*, which is formed from the Greek *ακη*, a point or edge.

ACINI, in botany, an appellation applied to grapes or berries growing in cluſters, to diſtinguiſh them from *baccæ*, or ſuch as grow ſingle.

ACINIFORMIS *Tunica*, in anatomy, the ſame with Uvea. See UVEA.

The word is compounded of the Latin *acinus*, a grape, and *forma*, ſhape.

ACKNOWLEDGMENT-MONEY, in law, implies a ſum of money paid to the tenant on the death of his landlord, as an acknowledgment of a new landlord.

ACLEA, in antiquity, ſignifies a place or field where oaks grow.

The word is compounded of the Saxon *ac*, an oak, and *leag*, a place.

ACLONIA, in botany, the name of a plant common in Guinea, where the inhabitants uſe it to cure the itch. Its leaves reſemble thoſe of the gum-tragacanth ſhrub, and is thought to be a ſpecies of the colutea.

ACKME, in a general ſenſe, implies the height, ſummit, or point of any thing.

The word is Greek, ακμη, implying the point or top, and ſeems to be a radix or root in that language.

Ackme, among phyſicians, ſignifies that ſtate of a diſeaſe when it is increaſed to its utmoſt violence.

ACNUA, in the agriculture of the ancient Romans, ſignified the length of one furrow, or the diſtance a plow goes before it is turned.

Acnua alſo ſignified a certain determinate meaſure, containing one hundred and twenty feet in length; and therefore may be properly called, in Engliſh, a furlong.

There were three ſorts of this meaſure among the ancients, the leaſt of which contained 120 feet in length, and 40 in breadth, being equal to a fourth part of the Roman jugerum or acre. The ſecond, which they generally called *actus quadratus*, contained 120 feet in length, and the ſame in breadth, being half the jugerum. The third contained 240 in length, and 20 in breadth, making the jugerum.

ACOEMETÆ, or Acoemeti, in eccleſiaſtical hiſtory, an ancient order of monks among the eaſtern chriſtians, who continued a perpetual courſe of divine ſervice; ſo that their churches were never ſilent.

The word is Greek, ακοιμηται, compounded of α priv. and κοιμαω, to ſleep.

They obtained this appellation, which properly ſignifies watchers, not from their never ſleeping, but from their performing divine ſervice continually night and day without intermiſſion; for, by dividing themſelves into three claſſes, each company officiated in their turn, and relieved the other.

The firſt monaſtery of the Acoemetæ was built by St. Alexander, on the banks of the Euphrates, about the year 430: but, during his life, a great number were erected by his diſciples. Alexander alſo eſtabliſhed another convent of Acoemetæ at Conſtantinople, which, after his death, was removed into Bithynia by John his ſucceſſor. John was ſucceeded by Marcellus, whom Nicephorus believed to be the inſtitutor, probably becauſe during his life this order of monks acquired, by their exemplary piety, the higheſt eſteem and veneration, and the number of their convents was prodigiouſly increaſed. Among others, one Studius, a nobleman of conſular dignity at Rome, became one of this order, renounced the world, and erected a famous monaſtery, which he dedicated to St. John the Baptiſt, calling it after his own name *Studium*, and the monks *Studitæ*. About a thouſand religious were ſettled in this houſe, which was a conſiderable time famous for a great many perſons eminent both in devotion and learning. But afterwards the Acoemetæ ſunk in their credit, by favouring the hereſy of the Neſtorians, and were at laſt condemned by the emperor Juſtinian, and pope John II. in the year 532.

Acoemetæ was alſo the name given to the Stilites, and other monks of Paleſtine.

There are ſtill a kind of Acoemetæ ſubſiſting in the Roman church, generally called the religious of the holy ſacrament, who keep up a perpetual adoration, ſome or other of them praying before the hoſt day and night.

ACOLIN, in natural hiſtory, is the name of a bird common in the Spaniſh Weſt-Indies. It is of the partridge kind; but not larger than the common ſtarling.

ACOLUTHI, or Acoluthists, in antiquity, was an appellation given to thoſe perſons who were ſteady and immoveable in their reſolutions: and hence the ſtoics, becauſe they would not forſake their principles, nor alter their reſolutions, acquired the title of Acoluthi.

The word is Greek, and compounded of α, priv. and κελευθος, way; as never turning from the original courſe.

Acoluthi, among the ancient chriſtians, implied a peculiar order of the inferior clergy in the Latin church; for they were unknown to the Greeks for above four hundred years. They were next to the ſub-deacon; and we learn, from the fourth council of Carthage, that the archdeacon, at their ordination, put into their hands a candleſtick with a taper, giving them thereby to underſtand, that they were appointed to light the candles of the church; as alſo an empty pitcher, to imply that they were to furniſh wine for the euchariſt. Some think they had another office, that of attending the biſhop wherever he went.

The word is Greek, and compounded of α, priv. and κωλυω, to hinder or diſturb.

The office of acoluthiſts, whatever the papiſts may advance to prove its apoſtolical inſtitution, is no longer in being in the church of Rome, but is changed into that of *Ceroferarii*, or taper-bearers, whoſe office it is to walk before the deacons, &c. with lighted tapers in their hands; an office very different from the acoluthiſts of the ancient church: and we may obſerve, in general, that the under-orders of the Roman bear no reſemblance to thoſe of the primitive church.

ACONEROBA, in botany, the name of a plant growing in Guinea, where it is greatly eſteemed for its virtues in the ſmall-pox. Its leaves reſemble thoſe of our bay, and grow in pairs.

ACONITE, the name of a genus of plants, known among us by the name of wolfsbane and monkſhood.

The flower of the aconite is of the polypetalous, anomalous kind, being compoſed of five irregular leaves, reſembling in ſome meaſure a man's head, with a helmet or hood on it. The upper petal repreſents the hood or helmet; the two lower ones ſtand for that part which covers the lower jaw; and the two wings ſeem adapted for covering the temples. From the center of the flower there ariſe two piſtils, reſembling feet, and received into the hollow of the upper petal, or hood; as is alſo another piſtil, which finally becomes a fruit, compoſed of ſeveral membranaceous vaginæ, collected into a head, and uſually containing angular and wrinkled ſeeds.

All the ſpecies of aconite are extremely acrimonious, and the only one ever uſed in medicine is called anthora. See the article Anthora.

ACONTIAS, in zoology, is a ſpecies of ſerpent, otherwiſe called jaculum, or the dart, from its vibrating its body in the manner of a dart.

The word is Greek, and derived from ακων, a dart.

Belon, or Bellon, met with it in the Iſle of Rhodes, and acquaints us that it is three palms in length, and about the thickneſs of a man's little finger; of a whitiſh aſh colour, except the belly, which is entirely white, and a few little ſpots like eyes upon the back. The neck is black, and from thence there run two white lines along the back to the tail. The ſpots, which are black, are no bigger than a lentil, and encompaſſed with a white circle. Authors affirm that they get upon trees, from whence they dart themſelves upon people as they paſs along, and that their bite is mortal. They are common in Egypt, Lybia, and the Iſlands of the Mediterranean ſea. Late authors mention different kinds of theſe ſerpents; and the following deſcriptions have been ſent to Europe from different parts of the world.

Seba ſpeaks of three kinds of darts, the firſt of which has a pointed tail, armed with two hard ſtrings like the forked tongues of ſome ſerpents. They lurk in hollow trees, where they wait for their prey, and dart upon it with great ſwiftneſs. This kind has a long head, large eyes, and jaws well furniſhed with ſharp teeth. The ſcales that cover the forehead and upper part of the body are uniform, regularly placed, and of a reddiſh blue colour, except a furrow in the middle, which is white; but the ſcales under the belly are of a pale yellow: mottled with red ſpots. This ſerpent was ſeen at Santa-cruz in America.

The dart of Amboyna is called by the Dutch ſpaitſlang, or the ſyringe ſerpent, becauſe it raiſes itſelf as ſwiftly as water ejected from a ſyringe. It is as thick as a man's arm, ſix feet in length, and covered with ſcales diſpoſed in the form of lozenges, tinged with a reddiſh brown, thoſe on the back and ſides of a ſea-green, and thoſe on the belly of a bright aſh colour. The ſkin is ſmooth, and the head of the middle ſize; the eyes are very large and ſhining; the teeth ſmall, and the tail long and pointed.

The acontia found in New Spain, is covered with yellow and reddiſh ſcales, placed in the form of lozenges, divided along the middle by ſtreaks running from the head to the end of the tail. The head is covered with yellow ſcales ſpeckled with red, and all its joints are of an orange colour; but the ſcales on the belly are of a reddiſh yellow. *Brookes's Nat. Hiſt.*

ACONTIAS, in natural hiſtory, is a name applied to a kind of comet or rather meteor, with a roundiſh or oblong head, and a long ſlender tail reſembling a dart or javelin; whence it has its name.

ACOPIS, in natural hiſtory, a precious ſtone tranſparent like glaſs, and ſpotted with a gold colour. *Pliny.*

The word is Greek, and compounded of α, priv. and κοπος, labour; becauſe oil, in which it had been boiled, was conſidered, by the ancients, as a remedy againſt wearineſs or laſſitude.

ACOPOS, in botany, is the name of a plant mentioned by Pliny, who ſays it is the anagris of Dioſcorides, and which Gerard conſiders as a ſpecies of trefoil.

ACORN, the fruit of the oak. See the article OAK.

ACORN, a genus of ſhell fiſh, of which there are ſeveral ſpecies.

The ſhells of theſe fiſh are of a longiſh ſhape, reſembling that of an acorn, and compoſed of ſeveral valves from ſix to twelve in number; but not moveable like thoſe of the bivalve kind, being fixed to each other by an intermediate ſubſtance.

The great furrowed ACORN-SHELL, *with a large mouth*, is the biggeſt of this kind, being about an inch and an half in height, and above an inch in diameter, where largeſt. It is broad at the baſe, and firmly fixed to a ſolid ſubſtance, and nearly of the ſame diameter at the top as at the baſe, where it is wide open. The mouth is not exactly round, nor the dyes even; it is compoſed of twelve valves, touching at the baſe, but receding from each other at the top. Theſe valves are furrowed longitudinally, and of a browniſh red; but the intermediate ſubſtance is of a lighter colour, and irregularly undulated in a tranſverſe direction. The inner ſurface is whitiſh, with a mixture of carnation and blue. The animal contained in this ſhell is of a triangular ſhape at the head, and has four pieces belonging to it, which ſerve to cloſe up the opening. It is found ſticking to the rocks in the Eaſt and Weſt-Indies.

The faſhioned ACORN-SHELL, *with a large mouth*, is uſually found in great cluſters, fixed to each other at the tops, which makes the ſurface of the whole appear like net-work, but there are large cavities underneath between their bodies. The ſhell is narroweſt at the baſe, where it is fixed to a ſolid body, and from thence becomes gradually wider to the top, where it is broad, open, and bent a little down at the edge, ſo as to appear ſomewhat like the ſhape of a bell. It is compoſed of eight firm, hard portions of a conical ſhape, connected by a firm ſhelly ſubſtance. The colour is of a browniſh grey, and the intermediate matter of a deeper brown. Theſe ſhells are brought from the American iſlands.

The Low ACORN-SHELL, *with a large mouth*, is three quarters of an inch high, and above half an inch in diameter. Theſe fiſh are found in large cluſters, and ſo cloſely connected, that the inner ſurface is more viſible than the outer. The colour of this ſhell is a pale whitiſh grey, with a mixture of brown, and a ſmall tinct of red. Each ſhell is compoſed of ſix parts, united together by a ſhelly ſubſtance. Theſe parts are full of furrows, and of a pale red, with a mixture of grey and brown. The ſhelly ſubſtance that unites them is of a paler red; and the largeſt part of the ſhell is near the baſe. The ſhape ſomewhat reſembles that of a drinking cup; whence it is, by ſome, called the cup-ſhell. It is found ſticking to the rocks and hard ſea-plants on the American ſhores.

The narrow-mouthed oval and greyiſh red ACORN-SHELL, is uſually found in cluſters of twenty or more together. They do not all ſtand upright, but are very cloſe at the baſe. A ſingle ſhell is about half an inch long, and a third of an inch in diameter, but ſomewhat narrower at the baſe than elſewhere. The edges at the top are drawn inward, yet leave a ſmall opening or mouth. It conſiſts of twelve portions, connected by a very ſmall ſhelly ſubſtance. Theſe valves are deeply furrowed, and of a duſky grey colour, tinctured with a paliſh red. It is brought from the Eaſt Indies and America.

The narrow-mouthed ſlender ACORN-SHELL is three quarters of an inch high, and one third of an inch in diameter, where largeſt, which is a little lower than the middle. The baſe is ſomewhat ſmaller, and the top much more ſo; for the edge is ſo contracted as to render the mouth ſmall. It conſiſts of eight portions connected by a thinner ſubſtance, and appear like ſo many ribs, of a roundiſh ſhape, riſing conſiderably in the middle. The colour is of a browniſh grey; but the intermediate matter conſiderably paler. It is common in the Eaſt Indies and on the coaſt of Africa.

The purple narrow-mouthed and ſlender ACORN-SHELL is three quarters of an inch high, and a little more than a third of an inch in diameter. It is largeſt at the baſe, from whence it grows gradually ſmaller to the top. Each ſhell is compoſed of ſix ribs, which touch each other at the baſe, and are connected by a thin ſhelly matter. The ribs are flatted with deep, but not regular, furrows, running longitudinally. The intermediate ſubſtance is undulated tranſverſly, and the edge ſo contracted as to form a narrow mouth. It is of a bright purple colour, though the ribs are deeper and more bluiſh, and the intermediate furrows more red.

The greyiſh-white furrowed ſlender ACORN-SHELL is ſeldom more than a third of an inch long, and two thirds leſs in its diameter. It is broadeſt at the baſe, and narroweſt at the top, where there is a ſmall mouth. The colour is of a greyiſh white, and the ſhell exceeding thin. It is compoſed of ſix portions, running taper from the baſe to the top. The furrows extend longitudinally, and are moſt diſtinct near the top. The intermediate matter is tranſverſly and irregularly undulated. It is common on the Engliſh ſhores.

The ſlender ACORN-SHELL, *with a narrow mouth*, is about half an inch in height, and hardly a quarter in diameter where largeſt, which is towards the middle, from whence it grows gradually ſmaller. The colour is of a duſky browniſh yellow on the ribs, and of a paler yellow between them. They are twelve in number, roundiſh and very narrow, ſtanding at ſmall diſtances, from each other. It is brought from the Eaſt Indies, and is found ſticking to the bottom of the ſhips that come from thence. *Brookes's Natural Hiſt.*

ACORUS, in the materia medica, a name ſometimes given to the great galangal. See GALANGAL.

ACORUS *Verus*, the true acorus. See CALAMUS *Aromaticus*.

ACORUS *Adulterinus*, or ACORUS *Vulgaris*. See GLADIOLUS *Lutius*.

ACOUSMATICI, in antiquity, a name given to thoſe diſciples of Pythagoras, who had not finiſhed their five years probation. See PYTHAGOREAN *Philoſophy*.

ACOUSTIC, an epithet applied to ſuch particulars as relate to the ear, or the ſenſe of hearing.

The word is formed from the Greek ακȣϛικος, and derived from ακȣω, to hear.

ACOUSTIC *Duct*, in anatomy, a name ſometimes given to the external paſſage of the ear. See EAR.

ACOUSTIC *Inſtrument*, a ſort of tube reſembling in ſome meaſure a horn, the ſmaller end of which is placed in the ear, by which means the ſound is augmented, and acts with a greater force on the organ of hearing.

ACOUSTIC *Medicines*, ſuch as are proper for the cure of deafneſs. See the article DEAFNESS.

ACOUSTIC *Nerve*, the ſame with auditorius, or the auditory nerve. See AUDITORIUS.

ACQUEST, or AQUIST, in law, implies ſuch goods as were acquired by purchaſe or donation; in contradiſtinction to ſuch deſcended by inheritance.

ACQUIETANDIS *Plegiis*, in law, is a writ that lies for a ſurety againſt a creditor who refuſes to acquit the complainant after the debt is paid.

ACQUIETANTIA *de ſhiris & hundredis*, in law, ſignifies the privilege of being free from ſuit and ſervice in ſhires and hundreds.

ACQUITTAL, in law, implies a deliverance, or the freeing a perſon from the ſuſpicion of guilt.

ACQUITTAL is alſo uſed to imply a freedom from entries and moleſtations of a ſuperior lord for ſervice iſſuing out of lands.

ACQUITTANCE, a releaſe or diſcharge in writing for a ſum of money, witneſſing that the party has paid the ſaid ſum.

No man is obliged to pay a ſum of money if the demandant refuſes to give an acquittance, which is a full diſcharge, and bars all actions, &c. An acquittance given by a ſervant for a ſum of money received for the uſe of his maſter, ſhall be a good diſcharge for that ſum, provided the ſervant uſed to receive his maſter's rents, debts, &c.

ACRAPITAMBA, in natural hiſtory, the name of a fiſh found on the coaſt of Braſil. It has an oblong body like a barbel, and grows to the length of two feet and better. The mouth is ſmall, furniſhed with teeth, and the eyes are large, with a red iris. The tail is about five inches long, and forked; and the ſcales are like thoſe of a carp, but of a blue purple colour. The lateral lines are of a gold colour, and an inch and half broad, running from the eyes to the tail: above theſe lines are golden ſpecks, and under them fine yellow lines running the whole length of the fiſh. The back-fin and the tail appear as if they were gilded, but thoſe on the belly and ſides are of a whitiſh yellow. The fins ſhine remarkably in the night. *Brookes's Natural Hiſt.*

ACRASIA, among phyſicians, implies the predominancy of one quality above another, either with regard to artificial mixtures, or the humours of the human body.

The word is Greek, and compounded of α, priv. and κεροννυμι, to mix; q. d. not mixed in a juſt proportion.

ACRE, a meaſure of land containing one hundred and ſixty ſquare poles or perches.

The word is formed from the Saxon *acher*, or the German *acker*, a field.

The French acre is equal to one and a quarter of the Engliſh; while that of Straſbourg is only about one half of the latter.

The word acre did not originally ſignify a determined quantity of land, but any open ground, eſpecially a wide champaign; and, in this antique ſenſe, it ſeems to be preſerved in the names of places, as Caſtle-acre, Weſt-acre, &c. When the word was applied to the meaſure of ground, the quantity was various till the thirty-third year of Edward I. when it was determined by act of parliament.

Acre-Tax, a tax levied upon lands at a certain rate by the acre, otherwiſe called acre-ſhot.

ACRID, an epithet applied to ſuch things as are of a ſharp, pungent, diſagreeable taſte.

ACRIDOPHAGI, in antiquity, the inhabitants of a kingdom in Ethiopia, ſaid to have lived on locuſts.

The word is Greek, and compounded of αχρις, a locuſt, and φαγω, to eat.

ACRIMONY, that quality in things which renders them acrid.

Acrimony *of the Humours*, a malignant quality which the fluids of the human body often acquire from a great variety of cauſes; particularly from a ſtagnation, or too violent a motion.

ACRIVIOLA, in botany, the ſame with *naſturtium indicum*. See Nasturtium.

ACROAMATIC, or Acroatic, a name given to thoſe lectures of Ariſtotle, as were calculated for his favourite diſciples and intimate friends; in contradiſtinction to his exerotic lectures, which were adapted to common hearers.

The word is Greek, ακροαματικος, and derived from ακροαμαι, to hear.

Acroamatic is alſo uſed in a more general ſenſe for any thing that is ſublime or abſtruſe: thus we read of Acroamatic philoſophy, theology, &c.

ACROATIC. See Acroamatic.

ACROMION, in anatomy, is a name given to the epophiſe or upper part of the ſcapula, or ſhoulder-blade, produced by an emiennce called epinus.

The word is Greek, and compounded of ακρος, extremity, and υμος, the ſcapula.

ACRONYCAL, in aſtronomy, is an appellation given to the riſing of a ſtar above the horizon at ſun-ſet; or its ſetting at ſun-riſing; for, in either caſe, the ſtar is ſaid to riſe or ſet acronycal.

The word is Greek, and compounded of ακρος, extremity, and νυξ, the night.

ACROSPIRE, the vulgar name for what the botaniſts call the germ of a plant.

ACROSPIRED, in malt-making, is a term applied to ſuch grains of the barley as ſhoot or ſprout out both at the blade and root-end. See Malt.

ACROSTIC, in poetry, a kind of poetical compoſition diſpoſed in ſuch a manner, that the initial letters of the verſes form the name of ſome perſon, kingdom, place, motto, &c.

The word is compounded of the Greek ακρος, extremity, and στιχος, verſe.

The acroſtic is conſidered by the critics as a ſpecies of falſe wit, and is therefore very little regarded by the moderns.

Acrostic is alſo a name given by ſeveral authors to two epigrams in the Anthologia, one of which is in honour of Bacchus, and the other of Apollo.

ACROSTICUM, in botany, is a name given by Linnæus to the ruta muraria of Tournefort, a diſtinct ſpecies of moſſes.

ACROSTOLIUM, among the ancients, ſignified the ornament placed on the extremity of the prows of their ſhips.

The word is Greek, ακροστολιον, and compounded of ακρος, extremity, and στολος, the prow.

ACROTERIA, in architecture, are ſmall pedeſtals upon which globes, vaſes, or ſtatues, are placed at the ends or center of pediments, or frontiſpieces. The height of the acroteria at the extremities ſhould be only one half of that of the tympanum; whereas that in the center ought to be one eighth more.

Acroteria alſo ſignify the figures placed as ornaments or crownings on the tops of churches: and ſometimes thoſe ſharp pinnacles, ſtanding in rows about flat buildings, with rails and baluſters, are called acroteria.

ACT, in a general ſenſe, implies whatever is performed either by the body or mind.

The word is Latin, *actus*, and derived from *ago*, to perform.

Act, in dramatic poetry, ſignifies a certain diviſion, or part of a play, deſigned to give ſome reſpite both to the actors and ſpectators.

The Romans were the firſt that divided their theatrical pieces into acts; for no ſuch diviſions appear in the works of the firſt dramatic poets. Their pieces indeed conſiſted of ſeveral parts or diviſions, which they called protaſis, epitaſis, cataſtaſis, and cataſtrophe; but theſe diviſions were not marked by any real interruptions on the theatre. Nor does Ariſtotle mention any thing of acts in his Art of Poetry. But in the time of Horace all regular and finiſhed pieces were divided into five acts.

> *Neuve minor, neu ſit quinto productior actu*
> *Fabula, quæ poſci vult & ſpectata reponi.*

The firſt act, according to ſome critics, beſides introducing upon the ſtage the principal characters of the play, ought to propoſe the argument or ſubject of the piece; the ſecond to exhibit this to the audience, by carrying the fable into execution: the third to raiſe obſtacles and difficulties: the fourth to remove theſe, or raiſe new ones in the attempt: and the fifth to conclude the piece, by introducing ſome accident that may unravel the whole affair.

But is it really neceſſary that a dramatic piece ſhould conſiſt of neither more nor leſs than five acts? The abbé Vatry is of opinion, that ſome pieces may, with propriety, conſiſt only of three acts, and others even of more than five; becauſe it is no ways eſſential that a tragedy ſhould conſiſt of fifteen or ſixteen hundred verſes. Among the ancients we find ſome that have no more than a thouſand; and, among the moderns, others which conſiſt of two thouſand. In the firſt caſe, three intervals or reſpites would be ſufficient; whereas in the ſecond, according to the opinion of the abbé d'Aubignac, five would not be enough: the diviſion into five acts is then an arbitrary rule, which may be violated without ſcruple. Tragedies, in general, ought indeed to conſiſt of five acts, and Horace had ſufficient reaſon to give a precept for that purpoſe; but it may be at the ſame time as neceſſary for a poet to divide his pieces into three, four, or ſix acts, as to ſpin out uſeleſs acts, which were, perhaps, before too long and embarraſſed with epiſodes, or crouded with incidents not eſſential to the plot. M. Voltaire has already got the better of that ancient prejudice in his *Death of Cæſar*, which, though an excellent tragedy, conſiſts of no more than three acts; and we have, in the Engliſh language, ſome of the ſame kind no way inferior to M. Voltaire's.

Acts are divided into ſcenes; and Voſſius remarks, that among the ancients, an act never contained more than ſeven ſcenes. We are very ſenſible that, in order to keep up a proper proportion between the length of the ſeveral acts, the number of ſcenes ſhould not be too much multiplied; but there is no fixed rule as to their number.

ACTS *of the Apoſtles*, one of the ſacred books of the New Teſtament, containing the hiſtory of the infant church, during the ſpace of twenty-nine or thirty years, from the aſcenſion of our Lord to the year of Chriſt 63.

It was wrote by St. Luke, and addreſſed to Theophilus, the perſon to whom that evangeliſt had before dedicated his Goſpel. We here find the accompliſhment of ſeveral of the promiſes made by our Saviour, his aſcenſion, the deſcent of the Holy Ghoſt, the firſt preaching of the apoſtles, and the miracles whereby their doctrines were confirmed; an admirable picture of the manners of the primitive Chriſtians; and, in ſhort, every thing that paſſed in the church till the diſperſion of the apoſtles, who ſeparated themſelves in order to propagate the Goſpel throughout the world. From the period of that ſeparation St. Luke quits the hiſtory of the other apoſtles, who were then at too great a diſtance from him, and confines himſelf more particularly to that of St. Paul, who had choſen him for the companion of his labours. He follows that apoſtle in all his miſſions, and even to Rome itſelf; for it appears that the Acts were publiſhed in the ſecond year of St. Paul's reſidence in that city, or the thirty-ſixth year of the Chriſtian æra, and in the ninth or tenth of Nero's reign. The ſtile of this work, which was originally compoſed in Greek, is much purer than that of the other canonical writers; and it is obſervable, that St. Luke, who was much better acquainted with the Greek than with the Hebrew language, always in his quotations from the Old Teſtament, makes uſe of the Septuagint verſion. The council of Laodicea places the Acts of the Apoſtles among the canonical books, and all the churches have acknowledged it as ſuch without any controverſy.

ACT, in the univerſities, ſignifies a theſis maintained in public by a candidate for a degree, or to ſhew the capacity and proficiency of a ſtudent.

The candidates for a degree of bachelor and maſter of arts are to hold philoſophical acts; and thoſe for bachelor of divinity theological acts, &c.

At Oxford, the time when maſters or doctors complete their degrees is alſo called the *act*, which is held with great ſolemnity. At Cambridge they call it the *commencement*.

ACT *of Faith*, in the Romiſh church, is a day appointed by the inquiſition for the puniſhment of heretics, and the abſolution of the innocent.

The criminals are firſt led to church, where their ſentence, either of condemnation or abſolution, is pronounced, and the criminals ſurrendered up to the ſecular power. This is the laſt ſcene of a court which is at once a diſhonour to religion, and a diſgrace to humanity.

ACT, in philoſophy, an effective application of ſome power or faculty.

In this ſenſe, act ſtands oppoſed to power, or the capacity of acting, not the exertion of that capacity. The word act is indeed properly and primarily only applicable where the power might exiſt, without being exerted: but the ſchoolmen extend it further, defining it by the preſence of any power or perfection, even though it could not be abſent; in which ſenſe God himſelf is ſaid to be a moſt pure act, becauſe his perfections are always and neceſſarily preſent.

ACT, in logic, is particularly underſtood of an operation of the human mind.

Thus to diſcern and examine are acts of the underſtanding; to judge and affirm are acts of the will.

There are voluntary and ſpontaneous acts; the former are produced by the operation of the ſoul; the latter without its privity or participation.

ACT *of Parliament* is a poſitive law, conſiſting of two parts, the words of the act, and its true ſenſe and meaning; which being joined, make the law. The words of *Acts of Parliament* ſhould be taken in a lawful ſenſe. Caſes of the ſame nature are within the intention, tho' without the letter of the act; and ſome acts extend by equity to things not mentioned therein.

ACTIAN *Games*, in antiquity, were ſolemn games inſtituted, or at leaſt reſtored, by Auguſtus, in memory of the victory he obtained over Mark Anthony at Actium.

Stephanus, and ſome other authors after him, pretend that they were celebrated every three years; but the more general opinion, founded upon the teſtimony of Strabo, who lived in the time of Auguſtus, is, that they were held only every five years, and celebrated in honour of Apollo, ſince called Actius.

ACTIAN *Years*, in chronology, a ſeries of years reckoned from the æra of the battle of Actium, otherwiſe called the æra of Auguſtus.

ACTION, in a general ſenſe, implies nearly the ſame thing with act. See ACT.

Grammarians, however, obſerve ſome diſtinction between *action* and *act*; the former being generally reſtricted to the common or ordinary tranſactions; whereas the latter is uſed to expreſs thoſe which are remarkable. Thus we ſay, it is a good *action* to comfort the unhappy; it is a generous *act* to deprive ourſelves of what is neceſſary for their ſake. The wiſe man propoſes to himſelf an honeſt end in all his *actions*; a prince ought to mark every day of his life with ſome *act* of greatneſs.

The abbé Girard makes a further diſtinction between the words *action* and *act*. The former, according to him, has more relation to the power that acts than the latter; whereas the latter has more relation to the effect produced than the former: and hence the one is properly the attribute of the other. Thus we may properly ſay, "Be ſure to preſerve a preſence of mind in all your *actions*; and take care that they are all *acts* of equity."

ACTION, in mechanics, implies either the effort which a body or power makes againſt another body or power, or the effect itſelf of that effort.

As it is neceſſary in works of this kind to have a particular regard to the common language of mechanics and philoſophers, we have given this double definition: but the proper ſignification of the term is the motion which a body really produces, or tends to produce in another; that is, ſuch is the motion it would have produced, had nothing hindered its effect.

All power is nothing more than a body actually in motion, or which tends to move itſelf; that is, a body which would move itſelf if nothing oppoſed it. The action therefore of a body is rendered evident to us by its motion only, and conſequently we muſt not fix any other idea to the word action, than that of actual motion, or a ſimple tendency to motion. The famous queſtion relating to *vis viva*, and *vis mortua*, owes, in all probability, its exiſtence to an inadequate idea of the word action; for had Leibnitz and his followers obſerved, that the only preciſe and diſtinct idea we can give to the word force or action, reduces it to its effect, that is, to the motion it actually produces or tends to produce, they would never have made that curious diſtinction. See FORCE.

Quantity of ACTION, a name given by M. de Maupertuis, in the Memoirs of the Pariſian Academy of Sciences for 1744, and in thoſe of Berlin for 1746, to the product of the maſs of a body by the ſpace which it runs through, and by its celerity. He lays it down as a general law, "that in the changes made in the ſtate of a body, the quantity of action neceſſary to produce ſuch change is the leaſt poſſible." This principle he applies to the inveſtigation of the laws of refraction, of equilibrium, &c. and even to the ways of acting, employed by the

Supreme Being. In this manner M. de Maupertuis attempts to connect the metaphyſics of final cauſes with the fundamental truths of mechanics, to ſhew the dependence of the colliſion of both elaſtic and hard bodies upon one and the ſame law, which before had always been referred to ſeparate laws; and to reduce the laws of motion, and thoſe of equilibrium, to one and the ſame principle.

The ſame year that M. de Maupertuis communicated the idea of his principle, profeſſor Euler printed a work, entitled, *Methodus inveniendi lineas curvas maximi vel minimi proprietate gaudentes*; in a ſupplement to which he demonſtrates, that, in the trajectories which bodies deſcribe by central forces, the velocity multiplied by what the foreign mathematicians call the element of the curve, always makes a minimum, which is an application of the ſaid principle to the motion of the planets.

It appears from the Memoir of 1744, that it was the reflections of M. de Maupertuis on the laws of refraction which led him to the theorem here mentioned. The principle which M. de Fermat, and after him M. Leibnitz, made uſe of for accounting for the laws of refraction, is ſufficiently known. Thoſe mathematicians pretended that a particle of light in its paſſage from one point to another, through two mediums, in each of which it moves with a different velocity, muſt do it in the ſhorteſt time poſſible: and, upon this principle, they have demonſtrated, by geometry, that the particle cannot go from one point to the other in a right line; but, having reached the ſurface which ſeparates the two mediums, it muſt alter its direction in ſuch manner, that the ſine of its incidence ſhall be to the ſine of its refraction, as its velocity in the firſt medium is to its velocity in the ſecond; whence they deduced the well-known law of the conſtant ratio of the ſines. See SINE and REFRACTION.

This explanation, though very ingenious, is liable to one great difficulty, namely, that the particle muſt approach towards the perpendicular in that medium where its velocity is the leaſt, and conſequently reſiſts it the moſt, which ſeems contrary to all the mechanical explanations of the refraction of bodies hitherto advanced, and of the refraction of light in particular. Sir Iſaac Newton's method of accounting for it is the moſt ſatisfactory of any hitherto offered, and gives a clear reaſon of the conſtant ratio of the ſines, by aſcribing the refraction to the attractive force of the mediums: whence it follows, that the denſeſt mediums, whoſe attraction is the ſtrongeſt, ſhould cauſe the ray to approach the perpendicular; a fact confirmed by experiment. Now the attraction of the medium could not cauſe the ray to approach towards the perpendicular, without increaſing its velocity, as may be eaſily demonſtrated. According to Newton, therefore, the refraction muſt be towards the perpendicular when the velocity is increaſed, which is contrary to the law of de Fermat and Leibnitz.

M. de Maupertuis has attempted to reconcile Sir Iſaac Newton's explanation with metaphyſical principles. Inſtead of ſuppoſing, as the above gentlemen do, that a particle of light proceeds from one point to another in the ſhorteſt time poſſible, he aſſerts that a particle of light paſſes from one point to another, in ſuch a manner, that the quantity of action is the leaſt poſſible. This quantity of action, ſays he, is a real expence, in which nature is always frugal. In virtue of this philoſophical principle, he diſcovers, that not only the ſines are in a conſtant ratio, but alſo that they are in the inverſe ratio of the velocities (agreeable to Sir Iſaac's explanation), and not in the direct ratio, as had been pretended by de Fermat and Leibnitz.

It is remarkable that of the many philoſophers who have treated on the ſubject of refraction, none ſhould fall upon ſo ſimple a manner of reconciling metaphyſics with mechanics; ſince no more is neceſſary than the making a ſmall alteration in the calculus founded upon M. de Fermat's principle. In reality, according to that principle, the time, that is, the ſpace divided by the velocity, ſhould be a minimum: ſo, calling the ſpace run through in the firſt medium S, with the velocity V, and the ſpace run through in the ſecond medium s, with the velocity v, we ſhall have $\frac{S}{V} + \frac{s}{v}$ = a minimum; that is, $\frac{\dot{S}}{V} + \frac{\dot{s}}{v} = 0$. Now it is eaſy to perceive, that the ſines of incidence and refraction, are to each other as $\dot{S}$ to $-\dot{s}$; whence it follows, that thoſe ſines are in the direct ratio of the velocities V, v, which is agreeable to M. de Fermat's rule. But, in order to have thoſe ſines to be in the inverſe ratio of the velocities, it is only ſuppoſing $\dot{V} S + \dot{v} s = 0$, which gives $S \times V + s \times v =$ a minimum. See MINIMUM.

In the Memoirs of the academy of Berlin, above cited, may be ſeen the other applications M. de Maupertuis has made of this principle. And we will add, that whatever may be determined with regard to the metaphyſical baſis of this principle, and even to the conception he has annexed to the quantity of action, it will ſtill hold good, that the product of the ſpace by the velocity is a minimum in the moſt general laws of nature.

ACTION, in poetry, is the ſubject or fable of the poem.

Critics generally diſtinguiſh two kinds, the *principal*, and the *incidental*. The principal action is what is generally called the fable, and the incidental an epiſode. See EPISODE.

As poems are divided into epic and dramatic, ſo each of theſe has alſo its particular action. That of the dramatic poem ought to be one, intricate, unravelled, and complete: but at the ſame time much ſhorter than that of an epic poem.

The action of an epic poem ought to be great, one, entire, marvellous, and of a competent duration.

Firſt, it ought to be great, that is, noble and intereſting; a common, ordinary adventure not furniſhing, from its own ſtock, the inſtructions intended to be conveyed by an epic poem. The action muſt be important and heroic. Thus, in the Æneid, a hero eſcaped from the ruins of his country, wanders a long time with the remainder of his fellow citizens, who had choſe him for their leader, and, in ſpight of Juno's anger, who purſues him without intermiſſion, he arrives in a country which the Fates had promiſed him; defeats very formidable enemies; and, after ſurmounting a thouſand difficulties, with a ſagacity equal to his valour, he there lays the foundation of a powerful empire. Thus the conqueſt of Jeruſalem by the Cruſaders; that of the Indies by the Portugueze; and the reduction of Paris by Henry the Great, in ſpight of the utmoſt efforts of the League, are the ſubjects of the poems of Taſſo, Camoëns, and M. de Voltaire: whence it is eaſy to conclude, that a common ſtory, an amorous intrigue, or ſome other ſimilar adventure, which affords a foundation for romances, can never become the fable of an epic poem; becauſe it requires nobleneſs and majeſty in the ſubject.

There are two methods of rendering the epic action intereſting: firſt, by the dignity and importance of the perſonages; this is the artifice of Homer, who has nothing elſe important in his models; every other particular might happen to common perſons. The ſecond is the importance of the action in itſelf, as the eſtabliſhment or abolition of ſome religion or ſtate; ſuch is the ſubject choſen by Virgil, and in this he doubtleſs excels Homer. The action of the Henriade reunites, in a pleaſing manner, this double advantage. But Milton, in both particulars, excels them all.

F. le Boſſu adds a third method for rendering the action intereſting, viz. the giving the readers an higher idea of the perſonages of the poem than what they commonly entertain of mankind; and by comparing the heroes of the poem with the preſent race of mortals.

The action ought to be one, that is, the poet ought to confine himſelf to one ſingle illuſtrious enterprize, executed by his hero, and not take the whole hiſtory of his life. The Iliad is no more than the hiſtory of the anger of Achilles, and the Odyſſey that of Ulyſſes's return to Ithaca. Homer would neither deſcribe the entire life of the latter, nor the whole of the Trojan war. On the contrary, Statius, in his Achilleid, as well as Lucan in his Pharſalia, has heaped together too many ſingle events, in order to give their works the name of epic poems. They may indeed be called heroic, becauſe they treat of heroes; but we muſt be careful not to confound the unity of the hero with the unity of the action. The life of man is full of inequality, and his deſigns inceſſantly changing, either from the inconſtancy of his paſſions, or the unforeſeen accidents of life. He who would deſcribe the whole man would form but an odd picture, a contraſt of oppoſite paſſinos, without either order or connection. Epic poetry therefore is not the praiſe of an hero, whom we propoſe as a model, but the recital of ſome great and illuſtrious action, which is given as an example.

It is the ſame of poetry as in painting, the unity of the principal action does not hinder us from introducing ſeveral particular incidents, and thoſe incidents are called epiſodes. The deſign is formed from the beginning of the poem; the hero of it attains his end by ſurmounting every obſtacle; and it is the recitals of thoſe oppoſitions which make the epiſodes. However, all thoſe epiſodes depend upon the principal action, and are ſo connected with it, and ſo united with each other, that we never loſe ſight either of the hero or the action which the poet propoſes to celebrate; at leaſt, we ought inviolably to purſue that rule, if we intend to preſerve the unity of the action.

As to the integrity or entireneſs of the action, it muſt, according to Ariſtotle, have a beginning, a middle, and an end; a precept which, though in itſelf very obſcure, is explained by F. le Boſſu in the following manner: The beginning, ſays he, comprehends thoſe cauſes which influence the action, and the reſolution that ſome perſon takes to perform it; the middle is the effect of thoſe cauſes, and the difficulties which attend their being carried into execution; and the end is the unravelling and ceſſation of thoſe difficulties.

The poet, adds the ſame author, ſhould begin his action in ſuch a manner as to enable the reader to underſtand whatever is to follow; and the rather, as ſuch a beginning neceſſarily requires a ſequel. Theſe two principles, taken reverſely, may likewiſe ſerve for the end; that is, the end muſt leave nothing to be expected, and neceſſarily be the ſequel of ſomething which went before. In ſhort, the beginning muſt be connected with the end by means of the middle, which is the effect of ſomething that preceded it, and the cauſe of that which follows.

Two oppoſite plans are remarkable in the cauſes of an action. The firſt, and principal, is that of the hero; the ſecond comprehends the deſigns which oppoſe his project. Thoſe oppoſite cauſes likewiſe produce contrary effects, viz. endeavours on the hero's part to execute his plan, and contrary efforts on the part of thoſe who oppoſe him. As the cauſes and deſigns, both of the hero and the other perſonages of the poem, make the beginning of the action; ſo the contrary efforts make the middle of it, when the knot or intrigue is formed, and in which the greateſt part of the poem conſiſts.

The removing of the obſtacles conſtitutes the unravelling; and this unravelling may be brought about two ways, either by an acknowledgement, or without it, though the latter takes place only in tragedy: whereas in an epic poem, the different effects produced by the unravelling, and the different conditions in which it leaves the perſonages of the poem, divide the action into ſo many branches. If it alters the fate of the principal perſonages, we ſay there is a peripetia, and then the action is complicated: if there be no peripetia, and the unravelling worked up by paſſing from a ſtate of trouble to a ſtate of repoſe, we ſay, the action is ſimple.

The action of an epic poem ought to be marvellous; that is, full of bold actions, which have however an air of probability. Such is the intervention of heathen deities in the poems of the ancients, and that of the paſſions perſonified in thoſe of the moderns. But tho' the poet may ſometimes go beyond nature, he ought never to ſhock reaſon. An action may be either ſagaciouſly or ridiculouſly marvellous.

With regard to the duration of the action of an epic poem, Ariſtotle obſerves, that it is leſs confined than that of tragedy. The latter ought to be included in the ſpace of one day, or, as they ſay, between two ſuns; but an epic poem is not confined in reſpect to time. In fact, tragedy is replete with violent paſſions, and nothing that is violent can be of long duration; but virtues and habitudes, which are not acquired inſtantaneouſly, are proper for an epic poem, and conſequently its action ought to have a greater extent. F. le Boſſu lays it down as a rule, that the more violent the paſſions of the principal perſons are, the leſs time the action ought to laſt; and conſequently that the action of the Iliad, the ſoul whereof is Achilles's anger, laſts but ſeven and forty days; whereas that of the Odyſſey, where prudence is the prevailing quality, laſts eight years and a half; and that of the Æneid, where the principal perſonage is a pious and humane hero, nearly ſeven years.

But the rule of the above author is not inconteſtable, nor are his ſentiments, either with regard to the duration of the Odyſſey or that of the Iliad, exact; for though the epopee may include in its narration the actions of ſeveral years, yet the critics are generally of opinion, that the time of the principal action, from the place where the poet begins his narration, ſhould not be longer than one year, as the time of the action of a tragedy ought to be at moſt but one day. Ariſtotle and Horace, however, ſay nothing of this matter: but the examples of Homer and Virgil prove it. The duration of the Iliad is but forty-ſeven days: the Odyſſey does not commence till the departure of Ulyſſes from the iſland of Ogygia: and the Æneid at the tempeſt which threw Æneas upon the coaſt of Carthage. Now, reckoning from theſe two epochs, the action of the Odyſſey is but of two months continuance, and that of the Æneid one year. It is true that Ulyſſes, while with Alcinoüs, and Æneas, while he ſtays with Dido, relate their paſt adventures; but theſe recitals are introduced merely as ſuch, in the duration of the principal action, and the courſe of years which were taken up by thoſe events make no part of the duration of the poem; as in tragedy, the events related in the protaſis, and which only tend to explain the dramatic action, make no part of its duration; therefore the error of F. le Boſſu is ſufficiently evident.

ACTIONS, in ethics, are the voluntary actions of a man, conſidered in reſpect to the imputation of their effects in common life.

By voluntary actions we underſtand thoſe which depend upon the human will, conſidered as a free agent, without whoſe determination, cauſed by ſome of its immediate acts, and preceded by the knowledge of the underſtanding, they cannot be performed; and conſequently the exiſtence or non-exiſtence of them is in the power of every perſon.

Every voluntary action includes two particulars; the matter of the action, and its form. The firſt is the motion itſelf of the natural faculty, or the actual uſe of that faculty conſidered wholly in itſelf; the other is the dependence, or that motion of a decree of the will, in virtue whereof we conceive the action, as produced by a free cauſe, capable of determining itſelf. The actual uſe of the faculty, wholly conſidered in itſelf, ſhould be rather called the action of the will than a voluntary action; the latter being aſſigned only to the motion of the faculties, conſidered as dependant on a free determination of the will: but we likewiſe conſider voluntary actions, either abſolutely, or in themſelves, as phyſical motions, though produced by a decree of the will, ſo far as their effects may be imputed to man. When voluntary actions include, in their ideas, that reflected view, we call them human actions; and as a perſon is ſaid to be moral or immoral, according as the actions have either a good or bad tendency, that is, according as they agree or diſagree with the law, which is their rule. And hence human actions have likewiſe the title of morals, or moral actions.

Human actions, conſidered in the latter acceptation, include, in their eſſence, two particulars; their matter, and their form. The matter comprehends ſeveral particulars, as,

1. The phyſical motion of one of the natural faculties; for inſtance, of the motive faculty of the ſenſitive

appetite, of the exterior and interior ſenſes, &c. We might alſo place in this claſs the acts of the will themſelves, conſidered purely and ſimply in their natural exiſtence, ſo far as they are the effects flowing from a phyſical faculty.

2. The defect of ſome phyſical motion it is capable of producing; for we are equally obnoxious and puniſhable for the ſins of omiſſion as for thoſe of commiſſion.

3. It is not only our proper motions and habitudes, or the abſence of either in our own perſon, that can conſtitute the matter of our moral actions; but alſo the motions, the habits, and their abſence, which we find in others, provided the whole could and might be directed by our own will.

4. It is not the action of beaſts, or the operations of vegetables, and inanimated bodies in general, that can furniſh the matter of any moral action, ſince theſe ſpecies of beings are ſuſceptible of being directed by our will; and hence we ſee the reaſon why the owner of an ox that puſhes with his horns, was, by the Levitical law, obliged to make good the damage done by that beaſt, provided the owner was previouſly appriſed of the vicious nature of the creature.

5. The actions of another, of which we are the paſſive ſubject, may be the cauſe of a moral action, at leaſt ſo far as we have given room to commit ſuch action. Thus a woman, who has been violated, is conſidered as in ſome degree culpable, if ſhe imprudently expoſed herſelf by going to places where ſhe had no real buſineſs, and by that means put herſelf into the power of the raviſher.

The eſſence therefore of moral actions conſiſts in their imputability, if we may be allowed to apply that term to the quality whereby the effects of voluntary actions may be imputed to the agent as their author; and hence the agent is called the moral cauſe.

ACTION, in the military art, implies an engagement between two armies, or between two different bodies of troops. It is alſo uſed to ſignify ſome memorable act performed by ſome officer or commander.

ACTION, in law, denotes either the right of demanding, in a legal manner, what is any man's due; or the proceſs brought for recovering the ſame.

ACTIONS are either criminal or civil.

Criminal ACTIONS are to have judgment of death, as appeals of death, robbery, &c. or only judgment for damage to the injured, fine to the king, and impriſonment.

Under the head of criminal actions may likewiſe be ranked penal actions, which lie for ſome penalty or puniſhment, on the party ſued, whether it be corporal or pecuniary.

Alſo actions upon the ſtatute, brought on breach of any ſtatute, or act of parliament; by which an action is given that did not lie before; as where a perſon commits perjury to the prejudice of another, the injured party ſhall have an action upon the ſtatute. And laſtly, popular actions, ſo called, becauſe any perſon may bring them on behalf of himſelf and the crown, by information, &c. for the breach of ſome penal ſtatute.

Civil ACTIONS are divided into real, perſonal, and mixt.

Real ACTION is that whereby a man claims a title, lands, tenements, &c. in fee, or for life; and this action is either poſſeſſory, or anceſtral; poſſeſſory, where the lands are a perſon's own poſſeſſion or ſeiſin; anceſtral, when they were in the poſſeſſion or ſeiſin of his anceſtors.

Perſonal ACTION, is that brought by one man againſt another, upon any contract for money or goods, or on account of treſpaſs, or other offence committed; and thereby the debt, goods, chattels, &c. claimed.

Mixt ACTION, one lying as well for the thing demanded as againſt the perſon who has it; and on which the thing is recovered with damages for the wrong ſuſtained: ſuch is an action of waſte ſued againſt a tenant for life, the place waſted being recoverable, with treble damages, for the wrong done.

All actions ſeem to be temporary. A real action may be preſcribed againſt in five years after a fine levied, or recovery ſuffered. Writs of formedon for any title to lands in being, muſt be ſued out within twenty years. Actions of debt, account, detinue, trover, and treſpaſs, are to be brought within ſix years; of aſſault and battery within four years; and of ſlander within two years, after cauſe of action, and not afterwards. However, it ought to be obſerved, that the right of action in theſe caſes is ſaved to infants, feme coverts, and perſons in priſon, or beyond ſea, &c. ſo as they commence their ſuits within the time limited after their imperfections are removed.

Actions may be brought againſt all perſons whatever; but thoſe who are attainted of high treaſon or felony, or outlawed or excommunicated perſon, &c. cannot bring any action till pardoned, abſolved, &c. A feme covert muſt ſue with her huſband, and infants by their guardians.

ACTION *upon the Caſe*, a general action which lies for the redreſs of wrongs and injuries done without force, and which, by law, are not provided againſt.

This at preſent is the moſt frequent of all actions, being brought in all caſes, where no certain form has been eſtabliſhed; and the reaſon why it is called an action upon the caſe, is becauſe the whole cauſe or caſe is ſet forth in the writ. It may be brought as well where there is another action, as where no other lies.

ACTION *upon the Caſe for Words*, is brought where a perſon is injured in his reputation; and for words which affect the life, office, trade, &c. or tend to the loſs of preferment in marriage, or otherwiſe; or to the diſinheritance or other damage of a perſon.

Prejudiced ACTION, otherwiſe called *preparatory*, one which ariſes from ſome doubt in the principal; as, where one ſues his younger brother for lands deſcended from the father, on which it is objected to him that he is a baſtard; here this point of baſtardy is to be firſt tried or adjudged before the principal cauſe can proceed.

ACTION *of a writ*, is when a perſon pleads ſome matter by which is ſhewn, that the plaintiff had no cauſe to have the writ brought, though, perhaps, he may have another writ for the ſame matter. It is hence called a plea to the action of the writ, in contradiſtinction from a plea to the action.

ACTION, among phyſicians, is applied to the functions of the human body, whether vital, animal, or natural.

Vital actions are thoſe without which life could not be maintained. Such is the motion of the heart and lungs.

Under animal actions are comprehended the ſenſes, imagination, judgment, and voluntary motions, without which we could not live comfortably.

Laſtly, natural actions are thoſe, which, though not ſo immediately neceſſary to life but that we may live ſome time at leaſt without them, yet are abſolutely neceſſary to our well being: ſuch is digeſtion.

ACTION, in commerce, is a term uſed abroad for a certain part or ſhare of a public company's capital ſtock. Thus, if a company has 400000 livres capital ſtock, this may be divided into 400 actions, each conſiſting of 1000 livres. Hence a man is ſaid to have two, four, &c. actions, according as he has the property of two, four, &c. thouſand livres, capital ſtock.

The transferring of actions abroad is performed much in the ſame manner as ſtocks are with us. See STOCKS.

ACTION, in oratory, implies the expreſſion of the countenance, voice, geſture, &c. and which ought to be accommodated to the ſubject.

Action, ſays Cicero, is the eloquence of the body; it has two parts, the voice and the geſture; the one ſtrikes the ears, and the other the eyes: the two ſenſes, adds Quintilian, whereby we convey our ſentiments and paſſions into the ſouls of the hearers. Each paſſion has a tone of voice, an air and a geſture peculiar and proper to it.

The ancients uſed the word pronunciation in the ſame ſenſe; and this Demoſthenes conſidered as the ſecond requiſite in eloquence, laying it down as an acknowledged truth, that a middling diſcourſe, delivered with all the force and graces of action, will have a greater effect on the audience than the moſt eloquent diſcourſe deſtitute of that powerful charm.

Action, in horſemanſhip, implies the motion of the various parts of a horſe in doing his paces, &c.

Action *of the Mouth*, in horſemanſhip, ſignifies the motion of a horſe's mouth in champing on his bit, whereby he throws out a great deal of foam, which keeps his mouth always freſh. It is a mark of fire and vigour.

Action, in painting and ſculpture, is the attitude or poſition of the ſeveral parts of the face, body, and limbs of ſuch figures as are repreſented, and whereby they ſeem to be really actuated by paſſions. Thus we ſay, the action of ſuch a figure finely expreſſes the paſſions with which it is agitated: we alſo uſe the ſame expreſſion with regard to animals.

ACTIONARY, or Actionist, ſignifies the proprietor of an action, or of a ſhare in the foreign funds, or capital ſtock of a company.

ACTIVE, an epithet applied to that body or power which communicates motion to another: and, in this acceptation, the term *active* is oppoſed to *paſſive*.

Sir Iſaac Newton juſtly obſerves that the vis inertiæ, &c. of all bodies muſt have a tendency to diminiſh the quantity of motion in the univerſe; and conſequently that there is a neceſſity for certain active principles to recruit it: among which he places the cauſes of gravity and fermentation. He adds, that we find very little motion in the univerſe that does not flow from theſe principles: and, as the cauſe of gravity always ſubſiſts without being in the leaſt diminiſhed by a continual exertion of its force, it becomes a perpetual ſource of action.

Active *Principles*, in chemiſtry, are thoſe ſuppoſed to act of themſelves, without any neceſſity for the action of others.

The chemiſts, in general, diſtinguiſh the principles of bodies into *active* and *paſſive*. The former are ſpirit, oil, and ſalt; and thoſe of the latter, water and earth. But we can by no means admit of this diſtinction; becauſe, as thoſe principles are merely relative, they may become active in ſome reſpects, and paſſive in others. Nor does there appear the leaſt reaſon for placing water in the claſs of paſſive principles. Mr. Homberg, and ſeveral other chemiſts, make only one active principle, namely, ſulphur or fire, which they aſſert to be the ſource of every action in the univerſe. See Fire.

Active, in medicine, is applied to ſuch remedies as have a quick and lively action, or which exert their force ſuddenly and with vigour.

Active, in grammar, is applied to ſuch words as expreſs an action; and is therefore oppoſed to paſſive. The active performs the action, as the paſſive receives it. The fire *burns*, and the wood is *burned*. *Burns* is therefore an *active*, and *burned* a *paſſive* term.

Verbs are divided into active and paſſive: the former implies that the ſubject of the verb performs the action, as, *I love*; and the latter that the ſubject receives the action, as, *I am loved*.

We ſay that verbs have an active and a paſſive voice; that is, a ſucceſſion of terminations which expreſs an active ſenſe, and another ſeries of terminations that imply a paſſive ſenſe. This is undoubtedly juſt with regard to the Greek and Latin languages; but the Engliſh verbs have only an active voice, and it is by means of a periphraſis, and not by the aſſiſtance of a particular termination, that we expreſs a paſſive ſenſe.

ACTIVITY, the power of acting, or the active faculty.

Sphere of Activity, is that ſpace through which any body extends its virtue or influence.

ACTIUS, in mythology, is a ſirname of Apollo, from Actium, where he was worſhipped.

ACTOR, in a general ſenſe, implies every perſon that acts.

Actor, with regard to the Theatre, ſignifies a perſon who plays a part, or repreſents ſome perſon or character, in a dramatic performance. The women are called actreſſes, but comprehended under the general name of actors.

The drama conſiſted originally of nothing more than a ſimple chorus, who ſung hymns in honour of Bacchus; ſo that the primitive actors were only ſingers and muſicians.

Theſpis was the firſt that, in order to eaſe this unformed chorus, introduced a declaimer, who repeated ſome heroic or comic adventure. Eſchylus, finding a ſingle perſon tireſome, attempted to introduce a ſecond, and changed the ancient recitals into dialogues. Before his time, the actors daubed themſelves with the dregs of wine, and, being drawn upon a tumbrel, amuſed the ſpectators. Eſchylus was the firſt projector of theatres. He alſo dreſſed his actors in a more majeſtic manner, and introduced the cothurnus or buſkin.

Sophocles added a third, in order to repreſent the various incidents in a more natural manner: and here the Greeks ſtopped; at leaſt we do not find in any of their tragedies above three perſons in the ſame ſcene; perhaps they looked upon it as a rule of the dramatic poem never to admit more than three ſpeakers at a time on the ſtage; a rule which Horace has expreſſed in the following verſe:

Nec quarta loqui perſona laboret.

This however did not prevent their increaſing the number of actors in comedy. Before the opening of a play, they named their actors in full theatre, together with the parts they were to perform. The moderns have ſometimes brought a greater number of actors upon the ſtage, in order to increaſe the buſineſs by the variety of perſons; but this has often occaſioned a confuſion in the conduct of the piece.

The ancient actors were maſked, and obliged to raiſe their voice extremely, in order to make themſelves heard by the innumerable crowd of people who filled the amphitheatres: they were accompanied with a player on the flute, who played a prelude, gave them the tone, and played while they declaimed.

Actors were highly honoured at Athens, and deſpiſed at Rome, where they were not only denied all rank among the citizens, but even when any citizen appeared upon the ſtage, he was expelled his tribe, and deprived of the right of ſuffrage by the cenſors. Cicero, indeed, eſteems the talents of Roſcius, but he values his virtues ſtill more; virtues which diſtinguiſhed him ſo remarkably above all others of his profeſſion, that they ſeemed to have excluded him from the theatre. The French have, in this reſpect, adopted the ideas of the Romans; and the Engliſh thoſe of the Greeks.

Actor, in law, implies the proctor or advocate in civil courts or cauſes.

ACTORUM *Tabulæ*, in ancient hiſtory, were tables inſtituted by Servius Tullius, in which the births of children were regiſtered. They were kept in the treaſury of Saturnus.

ACTRESS, a woman who performs or acts ſome character on the ſtage.

ACTUAL, an epithet applied to ſuch things as truly and abſolutely ſubſiſt. Thus philoſophers uſe the terms actual heat, actual cold, &c. in oppoſition to virtual or potential; and divines, that of actual grace in oppoſition to habitual. See Heat, Cold, Grace, &c.

Actual *Sin*, that which is committed by the perſon himſelf, in oppoſition to original ſin, or that he contracted from being a child of Adam.

ACTUARIÆ *Naves*, in antiquity, were a kind of ſhips deſigned principally for ſwift ſailing.

ACTUARY, or Actuarius, a clerk whoſe buſineſs it is to regiſter the acts and conſtitutions of the convocation.

Among the ancient Romans the actuary was a notary, ſcribe, or clerk, who kept an account of the proviſions and corn delivered out to each ſoldier.

ACTUS, among the ancient architects, ſignified a meaſure in length equal to 120 Roman feet.

Actus, in ancient agriculture, implied the length of one furrow, or the diſtance a plough goes before it turns.

Actus *Minimus*, ſignified a quantity of land 120 feet in length, and four in breadth, equal to one fourth of the jugerum.

Actus *Major*, or Actus *Quadratus*, was a piece of ground in the form of a ſquare, whoſe ſide was equal to 120 feet, equal to half the jugerum.

ACTUS *Intervicenalis* implied a ſpace of ground four feet in breadth, left between the lands as a path or way.

ACUANITES, in eccleſiaſtical hiſtory, is the name given to one of the branches of the Manichees. See MANICHEES.

ACULEI, in natural hiſtory, the ſpines or prickles found upon ſeveral objects both in the animal and vegetable kingdom.

ACULER, in the manege, is ſaid of a horſe when in working upon volts, he does not go far enough forward at every motion, by which means his ſhoulders take up too little ground, and his croupe comes too near the center of the volt.

ACUS, in natural hiſtory, the name of two diſtinct genuſes of fiſhes, one called, in Engliſh, the needle or tobacco-pipe fiſh, and the other the gar-fiſh.

The former is about a foot and a half in length, but not thicker than a man's finger. It has two very ſmall fins near the gills and another on the back. See plate I. *fig.* 14.

The latter, often called the acus of Oppian, is alſo long and ſlender, and the back of a bluiſh green colour. The under mandible is longer than the upper, and both furniſhed with ſharp teeth. See plate I. *fig.* 15.

ACUTE, an epithet applied to ſuch things as terminate in a ſharp point or edge. And in this ſenſe it ſtands oppoſed to obtuſe.

The word is derived from the Greek *ακη*, a point or edge.

ACUTE *Angle*, in geometry, is that which is leſs than a right angle. See ANGLE.

ACUTE-ANGLED *Triangle*, is a triangle whoſe three angles are all acute.

ACUTE-ANGLED *Cone* is, according to the ancients, a right cone, whoſe axis makes an acute angle with its ſide.

ACUTE-ANGLED *Section of a Cone*, among the ancients, ſignified an ellipſis formed by a plane cutting an acute-angled cone. But Appollonius demonſtrated that ſuch a ſection might be made in any cone whatever.

ACUTE, in muſic, is applied to a ſound or tone that is ſharp or high, in compariſon of ſome other tone. In this ſenſe, *acute* ſtands oppoſed to *grave*.

ACUTE *Accent*. See the article ACCENT.

ACUTE *Diſeaſe*, among phyſicians, is that which moves with velocity to a criſis, and is attended with danger; and in this ſenſe *acute* ſtands oppoſed to *chronical*.

AD, in grammar, a Latin prepoſition, expreſſing the relation one thing bears to another. It is frequently uſed in the compoſition of Engliſh and French words, as well as thoſe of the Latin.

ADAGE, a proverb, or popular ſentence, containing ſome remarkable obſervation.

The word is formed from the Latin *adagium*, which, according to Scaliger, is compounded of *ad*, and *agor*.

Eraſmus has made a very large and valuable collection of the Greek and Roman adages; and Mr. Ray has done the ſame with regard to the Engliſh.

ADAGIO, in muſic, ſignifies the firſt and ſloweſt of the four principal degrees of time eſtabliſhed in the Italian muſic. When it is repeated, it ſignifies ſtill ſlower time.

The word is an Italian adverb, and ſignifies ſlowly, leiſurely, &c.

ADAMANT, a name given by ſome naturaliſts to the diamond. See the article DIAMOND.

ADAMI *Pomum*, Adam's apple; in anatomy, a protuberance in the fore part of the throat.

ADAMI *Pomum*, in botany, the name of a ſpecies of orange common in Italy.

ADAMICA *Terra*, in natural hiſtory, a ſalt, glutinous, fat, and mucilaginous ſubſtance, reſembling a jelly, found at the bottom of the ſea.

ADAMITES, in eccleſiaſtical hiſtory, the name of a ſect of ancient heretics, ſuppoſed to have been a branch of the Baſilidians and Carpocratians.

Epiphanius tells us, that they were called Adamites from their pretending to be re-eſtabliſhed in the ſtate of innocence, and to be ſuch as Adam was at the moment of his creation, whence they ought to imitate him in his nakedneſs. They deteſted marriage, maintaining that the conjugal union would never have taken place upon earth had ſin been unknown; and that the privilege of enjoying women, in common, was one of the rights which flowed from their eſtabliſhment in original purity.

This obſcure and deteſtable ſect did not at firſt laſt long; but it was revived in the twelfth century by one Tandamus, ſince known by the name of Tanchelin, who propagated his errors at Antwerp, in the reign of the emperor Henry V. He maintained that there ought to be no diſtinction between prieſts and laymen; and that fornication and adultery were meritorious actions. Tanchelin had a great number of followers, and was conſtantly attended by three thouſand of theſe profligates in arms. His ſect did not however continue long after his death: but another appeared under the name of Turlupins, in Savoy and Dauphiny, where they committed the moſt brutal actions in open day.

About the beginning of the fifteenth century, one Picard, a native of Flanders, ſpread theſe errors in Germany and Bohemia, particularly in the army of the famous Ziſca, notwithſtanding the ſevere diſcipline he maintained. Picard pretended that he was ſent into the world as a new Adam, to re-eſtabliſh the law of nature; and which, according to him, conſiſted in expoſing every part of the body, and having all the women in common. This ſect found alſo ſome partizans in Poland, Holland, and England: they aſſembled in the night; and it is aſſerted, that one of the fundamental maxims of their ſociety was contained in the following verſe:

Jura, perjura, ſecretum prodere noli.

Some learned men are of opinion, that the origin of the Adamites was much earlier than the eſtabliſhment of Chriſtianity, being perſuaded that Maacha, mother of Aſa, king of Judah, was high prieſteſs of Priapus; and that, in the nocturnal ſacrifices which the women performed to that obſcene idol, they appeared ſtark naked. But, however that be, the motives of the Adamites were very different from thoſe of the votaries of Priapus; for they borrowed, from paganiſm, only the ſpirit of debauchery, not the worſhip of that heathen god.

ADAPTERS, or ADOPTERS, among chemiſts, are veſſels in the form of hollow globes, having two mouths or apertures diametrically oppoſite to each other; one of which admits the neck of the retort; and the other is received, either by the mouth of another adopter, or into the mouth of the receiver.

ADAR, the name of the twelfth month of the eccleſiaſtical, and the ſixth of the civil year among the Hebrews. It conſiſts of twenty-nine days, and anſwers to the latter end of our February and the beginning of March.

The Jews faſt on the ſeventh of this month, on account of the death of Moſes; on the thirteenth in imitation of the Jews of Suſa, who then faſted to avert the evils with which they were threatened by Haman; on the fourteenth they celebrate the feaſt of Purim, in commemoration of their deliverance from the intended cruelty of Haman.

As the lunar year, which the Jews followed in their calculations, is ſhorter than the ſolar, by about eleven days, which at the end of three years make a month, they then intercalate a thirteenth month, which they call *Veader*, or the ſecond Adar.

ADARCE, among the ancients, was a kind of ſaltiſh concretion, found on reeds, graſs, &c. in the marſhes of Galatia. Its ſubſtance is lax and porous, like that of the baſtard ſpunge, and is conſidered as a deterſive, and proper for diſſipating tetters, freckles, and other cutaneous blemiſhes.

ADARCON, a Jewiſh gold coin, worth about fifteen ſhillings ſterling.

ADARME, in commerce, a ſmall Spaniſh weight, uſed at Buenos Ayres, and other parts of South America, nearly equal to our dram.

ADARTICULATION, a term uſed by ſome anatomiſts to ſignify that ſpecies of articulation generally called arthrodia. See ARTHRODIA.

ADATIS, in commerce, a name given to the muſlins brought from the Eaſt Indies. The fineſt are thoſe of Bengal, and run about three quarters wide.

ADDER, the vulgar name for the viper. See VIPER.

ADDER-STUNG, cattle are ſaid to be adder-ſtung when their udders are bit by the adder, or the hedge-hog. The general method of curing this is by an ointment compoſed of dragon's blood, barley-meal, and the white of eggs.

ADDER's-TONGUE, in botany, the Engliſh name of the ophiogloſſum See OPHIOGLOSSUM.

ADDICE, or ADZE, a kind of crooked ax, much uſed by ſhipwrights, coopers, &c.

ADDICTION, in the Roman law, a transferring, or making over, goods, &c. to another, either by ſale, or the ſentence of a court of judicature.

The word is formed from *addico*, one of the words uſed by the Roman judges when they allowed the delivery of the thing or perſon on whom judgment had paſſed. Hence the goods, thus adjudged by the prætor, were called *bona addicta*, and the debtors delivered up in the ſame manner to their creditors, *ſervi addicti*.

ADDITAMENT, ſomething added to another. Thus phyſicians call the ingredients added to a medicine already compounded, additaments.

ADDITION, in a general ſenſe, implies the uniting ſeveral things together, or adding one thing to another.

ADDITION, in arithmetic, the firſt of the four fundamental rules or operations of that ſcience, and conſiſts in finding a certain number equal to two or more numbers taken together, or in finding the moſt ſimple expreſſion of a number according to the eſtabliſhed notation; the number ſo found being called their ſum.

The algebraic ſign or character of addition is +, commonly pronounced *plus*. Thus 4 + 5 ſignifies the ſum or aggregate of 4 and 5, in reading which we ſay, four *plus* five.

The addition of ſingle numbers, or thoſe conſiſting of one digit only, is very eaſy. For example, it is evident that 5 and 8, or 5+8, make 13.

In compound numbers, addition is performed by writing down the given numbers in vertical columns, placing units under units, tens under tens, hundreds under hundreds, &c. and then taking ſeparately the ſum of all the columns. This will be rendered very plain, by an example. Suppoſe it were required to add together the numbers 2376 and 143, ſet them down in the proper ranks under each other, in the following manner:

$$\begin{array}{rl} 2376 & \\ 143 & \\ \hline 2519 & \text{ſum, or total.} \end{array}$$

Begin by adding the units, ſaying, 3 and 6 make 9, which write down under the column of units; then proceeding to the column of tens, ſay 4 and 7 make 11 (tens), which are equivalent to 1 hundred and 1 tens, ſet down therefore 1 ten under the column of tens, and keep 1 hundred in your memory to be carried to the column of hundreds; where ſay 1 (hundred) and 1 make 2, and 3 make 5 (hundreds), which therefore write under the column of hundreds; laſtly, proceeding to the column of thouſands, where there is but one digit or figure, write it under that column, and the ſum or total of theſe numbers collected, will be 2519, as above.

So that, to perform this operation, all the units of the firſt column muſt be collected or added; and if the ſum of the units does not exceed 9, ſuch ſum muſt be written under the column of units; but if it be greater than 9, the number of tens muſt be kept in memory to be carried to the next column of tens; and, in caſe there be any units over and above the tens, they muſt be ſet under the column of units; but if there be no overplus, then 0 muſt be put there, to ſignify that there are no units, and the tens only are to be carried to the next column of tens, where the ſame method is to be ſtrictly obſerved as in the foregoing; becauſe 10 units make 1 ten, 10 tens 1 hundred, 10 hundreds 1 thouſand, &c.

Thus to add together the numbers 76948 + 24630 + 1462 + 536; place them as in the former example:

$$\begin{array}{rl} 76948 & \\ 24630 & \\ 1462 & \\ 536 & \\ \hline 103576 & \text{ſum.} \end{array}$$

And, having drawn a line under them, ſay 6 and 2 make 8, and 8 make 16; where there are 1 ten and 6 units; write therefore 6 under the column of units, and keep in mind 1 (ten) to be carried to the column of tens, where ſay 1 (ten) and 3 make 4, and 6 make 10, and 3 make 13, and 4 make 17 (tens), equal to 1 hundred and 7 tens; wherefore, under the column of tens, write 7, and carry 1 hundred to the column of hundreds, where the operation is to be purſued, ſaying 1 (hundred carried) and 5 make 6, and 4 make 10, and 6 make 16 and 9 make 25 (hundreds), equal to 2 thouſands and 5 hundreds; wherefore place 5 under the column of hundreds, and carry 2 (thouſands) to that of thouſands, where ſay 2 (thouſands) and 1 make 3, and 4 make 7, and 6 make 13, equal to 13 thouſand; write therefore 3 under the column of thouſands, and carry 1 to the column of tens of thouſands, where ſay 1 (ten thouſand) and 2 make 3, and 7 make 10 (tens of thouſands, equal to 1 hundred thouſand); you muſt therefore write 0 under the column of tens of thouſands, to ſignify that there are none of that denomination, and place before it 1, which finiſhes the operation, and makes the ſum total 103576.

ADDITION *of different Denominations*. When the numbers are of different denominations, or when they contain, for example, pounds, ſhillings, and pence; or, yards, feet, and inches, &c. care muſt be taken to place pence under pence, ſhillings under ſhillings, pounds under pounds, &c. and work as before. Suppoſe, for inſtance, the following numbers were to be added, 240 *l.* 14 *s.* 6 *d.* + 86 *l.* 10 *s.* 4 *d.* + 4 *l.* 9 *s.* 3 *d.* diſpoſe them in the following manner:

$$\begin{array}{rrrl} \pounds. & s. & d. & \\ 240 & 14 & 6 & \\ 86 & 10 & 4 & \\ 4 & 9 & 3 & \\ \hline 331 & 14 & 1 & \text{ſum.} \end{array}$$

And, having drawn a line under, begin with the pence, ſaying 3 and 4 make 7, and 6 make 13 pence, equal to 1 ſhilling and one penny; write therefore 1 penny under the column of pence, and carry 1 ſhilling to the column of ſhillings, and ſay 1 and 9 make 10, and 4 make 14 ſhillings, equal to 4 ſhillings, and 1 to be carried to the tens of ſhillings, where ſay 1 and 1 make 2, and 1 make 3 (tens of ſhillings), which exceeding 1 pound by 1 ten ſhillings, ſet down 1 in the column of tens of ſhillings, and carry the ſuperfluous 2 tens of ſhillings, equal to 1 pound, to the column of units of pounds, and then add up the ſeveral numbers of pounds as has been before directed, and the ſum total will be found to be 331 *l.* 14 *s.* 1 *d.*

ADDITION *of Decimals* is performed in the ſame manner as that of whole numbers, as may be ſeen in the following example:

$$\begin{array}{r@{,}l} 475 & 673 \\ 126 & 73 \\ 32 & 067 \\ 1 & 333 \\ \hline 635 & 803 \end{array}$$

See the article DECIMAL.

In the addition of vulgar fractions, when two or more fractions are to be added into one ſum, reduce all the given fractions to ſimple fractions, of one unit, and one denominator, if they are not ſo already; then the ſum of the numerators, being made a numerator to the common denominator, make the fractional ſum ſought; which may be farther reduced as the caſe admits. See FRACTIONS.

Addition *of Algebra*, or the addition of indeterminate quantities, deſigned by letters of the alphabet, is performed by joining the quantities with their proper ſigns, and reducing thoſe which are capable of reduction, that is, ſimilar magnitudes. See SIMILAR and ALGEBRA.

Thus a, added to the quantity b, makes $a+b$, and a joined with $-b$, makes $a-b$, $-a$ and $-b$, makes $-a-b$, $7a$ and $9a$ makes $7a+9a=16a$; for $7a$ and $9a$ are ſimilar magnitudes.

When algebraical magnitudes, required to be added together, are compounded of ſeveral terms, of which ſome are ſimilar; for inſtance, if the polynomial $3a^2b^3-5cs^4-4dr+2s$, were to be added to the polynomial $-s+4cs^4-a^2b^3+4dr$, write down firſt one of theſe polynomials, juſt as it is given.

$$\begin{array}{l} 3a^2b^3-5cs^4-4dr+2s \\ \underline{-a^2b^3+4cs^4+4dr-s} \\ \underline{a^2b^3-cs^4 \quad * \quad +s} \text{ ſum.} \end{array}$$

Then diſpoſe the other polynomial under it in ſuch a manner that the ſimilar terms may fall directly under one another; draw a line under both thus diſpoſed, and, reducing ſucceſſively the ſimilar terms to their moſt ſimple expreſſion, the ſums of the two polynomials will be found to be $2a^2b^3-cs^4+s$, placing an aſteriſk or o under ſuch terms as totally deſtroy each other.

Note, ſuch quantities are called ſimilar, in algebra, as have the ſame letters, and preciſely the ſame number of letters; ſo $5abd$ and $2abd$ are ſimilar magnitudes, the former ſignifying that the magnitude abd is taken 5 times, and the ſecond that it is taken 2 times, in the whole; therefore it is taken 7 times, and therefore ſhould be written $7abd$, inſtead of $5abd+2abd$; and as the expreſſion $7abd$ is more ſimple than $5abd+2abd$, it is ſaid in this caſe to be reduced to the moſt ſimple expreſſion.

In order to diſcern ſimilar algebraic magnitudes readily, there is no need of giving attention to their coefficient; but the letters ſhould be written in alphabetical order. Notwithſtanding $2bad$, be the ſame thing as $2abd$ or $2dba$, yet care ſhould be taken not to invert the order of the alphabet; we ſhould not write $2abd$ inſtead of $2bad$, or of $2bda$. This ſerves to make the computation the clearer, $5abd$ and $2abd$ appear more like ſimilar magnitudes than $5bad$ and $2bda$, which yet are the ſame as the former. The quantities $3b^2c$ and $4b^2c$, are likewiſe ſimilar magnitudes; but the magnitudes $4a^3f$ and $2a^3$ are not ſimilar, though they have the common quantity a^3, it being eſſential to ſimilar magnitudes, to have the ſame letters and the ſame number of letters.

Obſerve farther, that poſitive quantities, or thoſe affected with the ſign $+$, are directly oppoſite to negative quantities, or thoſe preceded by the ſign of $-$: thus when the quantities propoſed to be added are ſimilar and affected with contrary ſigns, they wholly or partly deſtroy one another; that is, in caſe one be greater than the other, there is deſtroyed in the greateſt a part equal to the leaſt, and what remains is the difference between the greateſt and the leaſt, affected with the ſign of the greateſt.

Now as this operation, or reduction, falls always upon the coefficients: it is manifeſt that $5df$ and $-3df$, are reducible to $+2df$, ſince $+5df$ ſhews that the quantity df is taken 5 times, and $-3df$ alſo ſhews that the ſame quantity df is 3 times retracted: but the ſame quantity taken 5 times, and ſubducted 3 times, is the ſame as if taken but twice.

In like manner $+5fm$ and $-6fm$, will be reduced to $1fm$, or ſimply to fm; for $-6fm$ is the quantity fm 6 times ſubducted, and $+5fm$ is the ſame quantity taken 3 times; the remaining quantity fm muſt therefore be negative, and conſequently muſt be $-fm$. See NEGATIVE.

There are no algebraic quantities incapable of addition under the above rules; thus $\frac{3a}{c}+\frac{5a}{c}=\frac{8a}{c}$, $2\sqrt{ac}+7\sqrt{ac}=9\sqrt{ac}$; $6\sqrt{ab-xx}+7\sqrt{ab-xx}=13\sqrt{ab-xx}$. Alſo $6\sqrt{3}+7\sqrt{3}=13\sqrt{3}$. And farther, $a\sqrt{ac}+b\sqrt{ac}=(a+b)\sqrt{ac}$, by adding together the magnitudes a, b, which multiply the quantity $\sqrt{ac}$.

In like manner $\frac{2a+3c\sqrt{3axx-x^3}}{a+x}+\frac{3a\sqrt{3axx-x^3}}{a+x}=\frac{\overline{5a+3c}\times\sqrt{3axx-x^3}}{a+x}$, as $2a+3c+3a=5a+3c$.

Poſitive or affirmative fractions, having the ſame denominator, are added, by adding together their numerators, and placing the common denominator under the ſum: thus, $\frac{2ax}{b}+\frac{3ax}{b}=\frac{5ax}{b}$; $\frac{8a\sqrt{cx}}{2a+\sqrt{cx}}+\frac{17a\sqrt{cx}}{2a+\sqrt{cx}}=\frac{25a\sqrt{cx}}{2a+\sqrt{cx}}$; and $\frac{aa}{c}+\frac{bx}{c}=\frac{aa+bx}{c}$. See FRACTION.

Negative quantities are added exactly in the ſame manner as affirmative ones: ſo $-\frac{4ax}{b}$ and $-\frac{11ax}{b}=-\frac{15ax}{b}$; $-a\sqrt{ax}$ and $-b\sqrt{ax}=-\overline{a-b}\times\sqrt{ax}$.

When a negative quantity is to be added to an affirmative one, the affirmative muſt be diminiſhed by the negative, or the negative by the affirmative: ſo $+3-2=1$; $\frac{11ax}{b}$: and $-\frac{4ax}{b}=\frac{7ax}{b}=$ likewiſe $+2\sqrt{ac}$ and $-7\sqrt{ac}=-5\sqrt{ac}$.

Addition *of Irrationals*, or *Surds*. In theſe operations it muſt be obſerved, that if the ſurds are not of the ſame denomination, they muſt be made to be ſo: in which caſe, if they are commenſurable to each other, add the rational quantities without connecting them by any ſign; and to the ſum put the radical ſign. Thus $\sqrt{8}+\sqrt{18}=\sqrt{4\times2}+\sqrt{9\times2}=2\sqrt{2}+3\sqrt{2}=5\sqrt{2}=\sqrt{50}$. On the contrary, $\sqrt{5}$ and $\sqrt{7}$ being incommenſurables, their ſum will be $\sqrt{7}+\sqrt{5}$. See INCOMMENSURABLE and SURD.

Addition *of Logarithms*. See LOGARITHMS.

Addition *of Ratios*, is the ſame with compoſition of ratios. Se RATIO.

Additions, among diſtillers, ſignify all ſuch things as are added to the waſh or liquor, while fermenting, to increaſe the quantity and vinoſity of the ſpirit, or to give it a particular flavour. See DISTILLATION.

Additions, in law, denote the titles given to a man beſides his chriſtian and ſurname, implying his eſtate, degree, myſtery, trade, place of abode, &c.

Theſe additions were ordained to prevent one man's being moleſted inſtead of another, and that each individual might be certainly known, and bear his own burden.

Additions, in heraldry, ſignify ſome things added to a coat of arms as marks of honour, and therefore directly oppoſite to abatements.

ADDITIONAL, in a general ſenſe, implies ſomething added to the uſual ſum or quantity.

Additional *Duties*, in commerce, ſignify thoſe duties which are charged upon certain commodities, over and above what they uſed to pay formerly.

ADDITIVE, ſomething to be added. Thus we ſay additive quantities, ratios, equations, &c.

ADDRESS, in a general ſenſe, implies the conducting any affair with ſkill and propriety.

Address, in a particular acceptation, ſignifies a congratulation, petition, requeſt, or remonſtrance, preſented to the king in the name of ſome conſiderable body of men.

Address, in commerce, is the direction wrote on the back of a letter or packet, ſent by the poſt or ſome meſſenger.

The addreſs ſhould contain the name, quality, and place of abode, of the perſon to whom the letter or packet, is to be delivered, together with the province, county, city, town, or place, where the party reſides.

ADDUCTION, in anatomy, the action of the adductors, or adducent muſcles.

ADDUCTORS, or **Adducent** *Muſcles*, in anatomy, a general name for ſuch muſcles as ſerve to draw one part of the body towards another; and conſequently are antagoniſts to the abductors.

The word is formed from the Latin, *ad*, to, and *duco*, to lead, or draw.

Adductor *Indicis*, is a muſcle of the index, or fore-finger, ariſing from the internal part of the firſt bone of the thumb, and terminating in the firſt bone of the fore-finger, which it draws towards the thumb.

Adductor *Oculi*, is a muſcle of the eye, which, by its action, draws the pupil towards the noſe. It is alſo called Bibitorius, becauſe it directs the eye towards the cup in drinking.

Adductor *Pollicis*, is a muſcle of the thumb which riſes tendinous in common with the adductor indicis, and aſcends obliquely towards a broad termination at the ſuperior part of the firſt bone in the thumb: its uſe is to bring the thumb near the fore-finger.

Adductor *Pollicis Pedis*, is a muſcle of the great toe. It ariſes from the inferior part of the os cuneiforme tertium, and is inſerted into the internal part of the oſſa ſeſamoideia of the great toe, which it draws nearer the reſt.

ADELLA, or Adena, the Italian name of a fiſh, thought to be peculiar to the river Po, in Italy. It ſometimes increaſes to the weight of one thouſand pounds, and is taken with a monſtrous large hook faſtened to the end of a chain; and they are obliged to draw it out of the water with a yoke of oxen. It differs from a ſturgeon, both in being a river-fiſh, and in its bulk. When it arrives at a certain ſize, it loſes the barbs it had before, like thoſe of a ſturgeon. The fleſh of a ſturgeon is firm, and of a pleaſant taſte; but that of this fiſh is ſoft, and not ſo agreeable. The mouth is like that of a ſturgeon, but much larger, and divided a little obliquely; beſides, it is not ſo pointed as in a ſturgeon; add to this, that the colour of the back is whitiſh, and has a wooly appearance. *Brookes's Natural Hiſt.*

ADELPHIANI, in eccleſiaſtical hiſtory, a ſect of heretics, who always faſted on Sundays.

ADEMPTION, in the civil law, implies the revocation of a grant, donation, or the like.

ADENANTHERA, in botany, a genus of plants, whoſe flower is of a campanulated form, and conſiſts of five leaves. It is one of the decandria-claſs of Linnæus, with a long compreſſed pod, containing ſeveral round ſeeds.

ADENOGRAPHY, a deſcription of the glands.

The word is Greek, αδηνογραφια, compounded of αδην, a gland, and γραφω to deſcribe.

We have a treatiſe wrote by Wharton, entitled Adenography, printed in twelves, at London, in the year 1656; and another work under the ſame title, wrote by Nuck, and printed in octavo, at Leyden, in 1691; a ſecond edition of it was publiſhed in 1722.

ADENOIDES, glandulous, or of a glandular form; an epithet applied to the proſtatæ. See Prostatæ.

The word is Greek, and compounded of αδην, a gland, and ειδος, reſemblance.

ADENOSUS *Abſceſſus*, in ſurgery, a hard crude tumour, reſembling a gland, and very difficult to be reſolved.

ADEONA, in mythology, the name of a goddeſs invoked by the Romans when they ſet out upon a journey.

ADEPHAGIA, in mythology, the goddeſs of gluttony, to whom the Sicilians paid a religious worſhip.

ADEPS, in anatomy, ſignifies properly the hard fat, or ſuet, found in the abdomen, and diſtinguiſhed from pinguedo; but moſt writers uſe the two terms indifferently.

ADEPTS, a name given to thoſe alchymiſts who pretend to have diſcovered the philoſophers ſtone, and the univerſal remedy.

The word is formed from the Latin *adipiſcor*, to obtain; becauſe, according to Paracelſus, both the one and the other of the above ſecrets muſt be obtained from heaven.

ADEQUATE, in a general ſenſe, implies ſomething exactly correſponding to, or expreſſive of, another.

Adequate *Ideas*, are thoſe ideas which perfectly repreſent all the parts or properties of another. See Idea.

ADER, in natural hiſtory, the name of a very curious ſhell, of a fine ſky-blue colour, with yellow rays one over another towards the bottom. It is very ſmall, being never above a quarter of an inch in length, and three twelfths of an inch broad. It is pointed at the top, and has ſlight folds near the hinge, where there is alſo a ſmall cavity. Each valve has about fifty deep furrows running longitudinally from the top to the oppoſite extremity. The edges are all round decorated with ſmall teeth, equal in number with the furrows. When the cruſt is taken off, it appears to be of a ſhining violet colour. The ſhell on the inſide is generally white, though ſometimes of a dark violet. *Brookes's Nat. Hiſt*

ADESSENARIANS, in eccleſiaſtical hiſtory, a ſect of Chriſtians who maintained the real preſence in the euchariſt; but in a ſenſe different from what the Roman church calls tranſubſtantiation. Nor were the Adeſſenarians agreed among themſelves with regard to the mode in which the real preſence exiſted: ſome being perſuaded that the body of Chriſt is in the bread; others that it is about the bread; ſome that it is with the bread; and others that it is under the bread.

ADFECTED *Equations*, in algebra, is an equation wherein the unknown quantity is found in two or more different powers. Thus $x^3 - px^2 + 9x - r = 0$; and $x^4 + x^3 - 19x^2 - 49x - 30 = 0$, are adfected equations. See Equation.

ADFILIATION, a cuſtom uſed among the ancient Goths, and other northern nations, whereby the children of a former marriage were put upon the ſame footing with thoſe of the ſecond. This cuſtom is ſtill retained in ſome parts of Germany, under the title of *einkindſchafft*.

ADHATIDA, in botany, a genus of plants, whoſe flower conſiſts of a ſingle leaf divided into two lips, of which the upper is bent backwards, and the lower again divided into three ſegments. The piſtil, which is fixed into the lower part of the flower, in the manner of a nail, becomes a fruit or capſule, flat and divided into two cells, containing ſeveral ſmall compreſſed ſeeds.

ADHESION, in a general ſenſe, implies the ſticking or adhering of two bodies together, either by their own proper action, or by the compreſſion of ſome external fluid.

The word is Latin, *adheſio*, and compounded of *ad* to, and *hæro*, to cleave.

Anatomiſts often find in diſſections, adheſions of the lungs to the ſides of the thorax, pleura, or diaphragm; or of the heart to its pericardium, &c.

Adhesion, in philoſophy. See the article Attraction *of Coheſion*.

Adhesion, among logicians, implies the maintaining ſome tenet, merely on account of its ſuppoſed advantage, without conſidering whether it be ſupported by any poſitive evidence.

ADJACENT, an epithet applied to ſuch things as adjoin to or are ſituated near each other.

The word is formed from the Latin, and compounded of *ad*, to, and *jacio*, to caſt.

ADIANTHUM, maidenhair, in the materia medica, is an evergreen plant, with ſlender, ſmooth, ſhining, blackiſh ſtalks; producing no manifeſt flower. The ſeeds are a fine duſt, lying in roundiſh ſpecks about the edges of the backs of the leaves, which curl over and cover them. There are two ſpecies of this plant diſtinguiſhed by botaniſts in the following manner:

Adianthum *Verum*, or *Capillus Veneris*, true maidenhair. This plant is about half a foot high, with ſeveral pinnæ of little roundiſh ſinuated or nearly triangular leaves towards the tops of the ſtalks.

Adianthum *Canadenſe*, Canada madenhair; larger, with ſpreading branches.

The firſt ſort grows wild in Italy, and the ſouthern parts of France, from whence the dry leaves are ſometimes brought to us. The ſecond, a native of America, is cultivated in ſome of our gardens.

The leaves of both the maidenhairs have a ſlight ſweetiſh, roughiſh taſte, and a pleaſant, but weak ſmell, very perceptible when boiling water is poured on them. They readily give out to the water the whole of their ſmell, taſte, and medicinal virtue: the infuſions are not ungrateful; particularly that of the Canada ſort, whoſe flavour is both pleaſanter and ſtronger than that of the other. Infuſions or decoctions of them, inſpiſſated, yield a moderately rough, bitteriſh, mucilaginous extract. Rectified ſpirit of wine extracts their taſte and flavour, and gains from them a deep green colour, but diſſolves little of the mucilaginous ſubſtance, in which a conſiderable part of their virtue conſiſts: the extract obtained by inſpiſſating the tincture, is leſs in quantity, and ſtronger in taſte, than that made with water.

Maidenhair has long been held in eſteem againſt diſorders of the breaſt; for promoting expectoration, ſoftening recent coughs, and allaying the tickling in the throat occaſioned by defluxions of the rheum. For theſe purpoſes, a ſyrup of the true ſort, flavoured with a little orange-flower water, has been uſually brought from France; and a ſyrup of the Canada ſort, made with maple ſugar, is ſometimes received from America. The virtue of the maidenhair is obtainable, however, to much better advantage, by drinking an infuſion of the herb as tea, ſweetened either with ſugar, or by the addition of a little liquorice. The Engliſh maidenhair has been commonly ſubſtituted in the pectoral ſyrups and infuſions made among us: the Canada ſpecies, which appears to be ſuperior to both, is ſaid to have been long made uſe of in France, and has lately been introduced into practice in this country. *Lewis's Hiſtory of the Materia Medica.*

ADIAPHORISTS, in eccleſiaſtical hiſtory, a name given in the ſixteenth century to the moderate Lutherans, or thoſe that embraced the opinions of Melancthon, whoſe pacific diſpoſition was far from being ſuitable to the extreme vivacity of Luther. Since the year 1548, the name Adiaphoriſts has been applied to thoſe Lutherans who ſubſcribed to the Interim publiſhed by Charles V. at the diet of Augſburg.

The word is formed from the Greek, αδιαφορος, indifferent; compounded of α, priv. and διαφορος, different.

ADIAPHOROUS, an epithet given by Mr. Boyle to a ſpirit diſtilled from tartar, and ſome other vegetable ſubſtances. It is ſaid to be, in ſeveral reſpects, different from any other ſpirit, and to be neither acid nor alkaline.

ADJECTIVE, in grammar, a word which expreſſes ſome quality or other accident belonging to the ſubſtantive.

But as every quality ſuppoſes a ſubſtance, of which it is the quality; it follows, that every adjective ſuppoſes a ſubſtantive. If we ſay, the *fine* touches you; the *true* ought to be the ſubject of our enquiries; the *good* is preferable to the *handſome*, *&c.* it is evident that we conſider theſe qualities ſo far only as they are attached to ſome ſubſtance or agent: the *fine*, that is, the ſubſtance which is fine; the *true*, or that which is true, &c. In theſe examples the *fine*, the *true*, *&c.* are not merely adjectives: they are adjectives uſed ſubſtantively; they denote any agent whatſoever, provided that agent be fine, true, good, &c. It therefore follows, that theſe words are both adjectives and ſubſtantives at the ſame time; they are ſubſtantives becauſe they denote an agent; they are adjectives becauſe they aſſign a certain qualification to the agent.

There are as many ſpecies of adjectives as there are ſpecies of qualities, manners, and relations, which the human mind can conſider in the objects.

We do not know the eſſence of the ſubſtances themſelves, we know them only by the impreſſions they make upon our ſenſes; and therefore we give the object ſuch and ſuch qualities as are proper to the ſenſe thoſe impreſſions affect: if the eyes are affected, we ſay that the object is coloured; that it is either white, black, red, blue, &c. If it affects the taſte, we denominate it either ſweet, bitter, ſour, unſavory, &c. If it regards the ſenſe of feeling, the object is either rough, ſmooth, hard, ſoft, fat, oily, dry, &c. Conſequently the words white, black, red, blue, ſweet, bitter, ſour, unſavory, &c. are ſo many qualifications given to objects, and therefore ſo many adjectives; and becauſe theſe impreſſions are cauſed by the action of phyſical objects upon our ſenſes, we may properly call theſe words by the name of phyſical adjectives.

At the ſame time it will be neceſſary to obſerve, that there is nothing in the object ſimilar to the ſentiment they excite in us; all we can infer from hence is, that ſuch objects have the property of exciting in us ſuch a ſenſation, or ſuch a ſentiment, according to the diſpoſition of our organs, and the laws of univerſal mechaniſm. A needle, for inſtance, is ſuch an object, that if the point of it be forced into the ſkin, the party will feel a ſenſation of pain; but this ſenſation will be peculiar to the perſon affected, and not at all to the needle; we may ſay the ſame of every other ſenſation.

Beſides the phyſical, there are alſo metaphyſical adjectives, which are equally numerous, and from which we might form as many different claſſes as there are kinds of contemplations under which the mind may conſider phyſical and metaphyſical objects.

As we are accuſtomed to qualify phyſical beings, in conſequence of the immediate impreſſions they make upon us; ſo we alſo qualify metaphyſical and abſtract beings in conſequence of ſome conſiderations of our mental faculty, with reſpect to theſe beings. The adjectives that expreſs theſe ſpecies of contemplations are what we call metaphyſical adjectives. Perhaps the following examples will better explain what we mean by metaphyſical adjectives.

Let us ſuppoſe a row of trees in the midſt of a vaſt plain, and that two perſons are juſt entered this row, one at the one end, and the other at the other; each of thoſe, obſerving the trees of this row, ſays, this is the firſt; ſo that the tree which each perſon calls the firſt, is the laſt with regard to the other. Thus firſt and laſt, together with the other nouns of ordinal number, are nothing more than metaphyſical adjectives; or more properly, adjectives of relation and numeral affinity.

The nouns of cardinal numbers, ſuch as two, three, &c. are alſo metaphyſical adjectives, becauſe they ſerve to qualify a collection of individuals.

Great and little are alſo metaphyſical adjectives; for any object, whatſoever it be, is neither great nor little conſidered in itſelf; it acquires thoſe appellations only from its relation to ſome other object: that to which we have given the name of great, has cauſed in our mind a different impreſſion from what we call little; it is the perception of this difference which occaſions us to invent the names of great, little, leſs, &c.

Different, ſimilar, alike, are likewiſe metaphyſical adjectives, which qualify the ſubſtantives in conſequence of certain particular contemplations of the mind. The word different, for inſtance, qualifies a noun, when we feel it has not made impreſſions in our mind ſimilar to thoſe of another. Where two objects are ſo formed that we perceive they are diſtinct, though in ſome particulars they make ſimilar impreſſions on our mind, we ſay that they are ſimilar in theſe particulars, becauſe in that reſpect we find ourſelves affected in the ſame manner: ſimilar therefore is a metaphyſical adjective.

If we walk round a fortified city, we ſhall perceive that it is incloſed within its bulwarks; we obſerve a country bounded on the one ſide by a river, on the other by a foreſt; we ſee a picture incloſed in its frame, the extent whereof we can even meaſure, and the limits of which we plainly perceive: we place a book or a guinea upon a table, and obſerve that they occupy only a ſmall extent upon it; that the table fills but a ſmall ſpace of the chamber, and that the chamber itſelf is furrounded with walls; in ſhort, all bodies appear to be bounded by others, beyond which there is ſtill ſpace; theſe bodies therefore are bounded, terminated, and ended: thus bounded, terminated, and ended, are nothing more than metaphyſical adjectives; becauſe they imply only the bounds and knowledge of a further extenſion.

On the other hand, if we apply ourſelves to reckon any number whatſoever, whether it be the number of the ſands on the ſea ſhore, or of the leaves of all the trees growing upon the face of the earth, we ſhall perceive that this number can be increaſed, till at laſt, tired with innumerable additions, which are always poſſible, we ſay, that this number is infinite, or ſuch that we cannot perceive its limits, becauſe we can always increaſe the ſum total. The ſame may be ſaid of all extended bodies, the boundaries of which our imaginations can always remove, at laſt, to infinite extenſion; the term infinite, therefore, is a metaphyſical adjective.

Perfect is again another metaphyſical adjective: cuſtom ſhews us, that there are beings that have advantages of which others are deſtitute: we find that the former are therefore in that reſpect of more value than the latter: plants, flowers, and trees, are worth more than common ſtones; animals have qualities ſtill more preferable to thoſe of plants; and man has knowledge which raiſes him above animals. If we examine attentively two pictures of the ſame perſon, one whereof recals to our mind, in a very forcible manner, the image of that perſon, while the other excites only a faint idea; we ſay, that the picture ſpeaks, or that it is perfect, at leaſt, with reſpect to the other.

AD INQUIRENDUM, in law, is a writ commanding enquiry to be made about ſomething connected with a cauſe depending in the king's courts.

ADJOURNMENT, the putting off a court, or other meeting, till another day.

The word is formed from the Latin, *ad* to, and the French *jour*, a day, q. d. to another day.

There is a difference between the adjournment and the prorogation of the parliament; the former not only being for a ſhorter time, but alſo done by the houſe itſelf; whereas the latter is an act of royal authority.

ADIPOSE, an epithet applied by phyſicians, anatomiſts, &c. to ſeveral cells, ducts, and the like, as belonging to the fat of bodies.

The word is Latin, *adipoſa*; and derived from *adeps*, fat.

ADIPOSE *Membrane*, *Adipoſa Membrana*, in anatomy, is a particular membrane, inveſting the human body immediately under the ſkin, and ſuppoſed to be the baſis of the fat which is depoſited in its cells.

This is not however a ſingle membrane, but a congeries of a great number of membranous laminæ, joined irregularly to each other at different diſtances, ſo as to form numerous interſtices of different capacities communicating with one another.

ADIT *of a Mine*, the paſſage, or opening, through which the miners paſs into the mine.

The word is Latin, *aditus*, and ſignifies a way or paſſage.

ADJUDICATION, in law, implies the act of adjudging, or determining, a cauſe in favour of ſome perſon.

The word is Latin, *adjudicatio*, and compounded of *ad*, to, and *judico*, to give ſentence.

ADJUNCT, among philoſophers, ſignifies ſomething added to another, without being any neceſſary part of it. Thus water abſorbed by cloth or a ſpunge, is an adjunct, but no neceſſary part of either of theſe ſubſtances.

The word is Latin, *adjunctum*, and compounded of *ad*, to, and *jungo*, to join.

ADJUNCT, in metaphyſics, ſome quality belonging to either the body or mind, whether natural or acquired. Thus thinking is an adjunct of the mind, and growth an adjunct of the body.

ADJUNCT, in rhetoric and grammar, implies an epithet, or adjective, added for enlarging and augmenting the energy of a diſcourſe.

ADJUNCT is alſo uſed to ſignify a collegue, or ſome perſon aſſociated with another, as an aſſiſtant.

AD JURIS REGIS, in law, is a writ which lies for a clerk preſented to a living by the king.

ADJUTAGE, in hydraulics, is a tube fitted to the mouth of a jet d'eau. See the article AJUTAGE.

ADJUTANT, in military affairs, an officer whoſe buſineſs is to aſſiſt the major, and thence often called the aid-major.

The word is derived from the Latin *adjuvo*, to aſſiſt.

ADUTORIUM, among phyſicians, implies ſome medicine, generally a topical or external application, preſcribed as an aſſiſtant to another of more efficacy.

ADJUTORIUM, in anatomy, is a name given to a bone of the arm, generally called the humerus. See the article HUMERUS.

ADMEASUREMET, in law, is a writ for the adjuſting the ſhares of ſomething to be divided.

The word is formed from the Latin, *admenſuratio*, compounded of *ad*, and *metior*, to meaſure.

ADMINICLE, a term uſed, in our old law books, to imply any aid, help, aſſiſtance, or ſupport.

The word is Latin, *adminiculum*, and derived from *adminiculor*, to prop, or ſupport.

Antiquarians call the attributes of Juno, repreſented on medals, by the name of adminicles.

ADMINISTRATION, in a general ſenſe, implies the direction of government, or direction of affairs.

The word is Latin, *adminiſtratio*, and derived from *adminiſtro*, to manage or govern.

ADMINISTRATION, in law, ſignifies the office of an adminiſtrator.

ADMINISTRATOR, in law, ſignifies the perſon to whom the goods, effects, or eſtate, of one who died inteſtate, are intruſted, and for which he is accountable when required.

The biſhop of the dioceſe, where the party dies, is regularly to grant adminiſtration; but if the inteſtate has goods in ſeveral dioceſes, adminiſtration muſt be granted by the archbiſhop in the prerogative court.

ADMINISTRATRIX, a woman who acts as adminiſtrator.

ADMIRAL, a great officer, or magiſtrate, who has the government of a navy, and the hearing of all maritime cauſes.

Authors are divided with regard to the origin and denomination of this important officer, whom we find eſtabliſhed in moſt kingdoms that border on the ſea. Some borrow it from the Greeks, the captain of the ſeas, under the emperors of Conſtantinople, being called αμηραλιος, *admiralius*, a Greek term, compounded of αλμηος, *ſalina*, or αλμη, ſalt water, and αρχος, *princeps*; in regard his juriſdiction lay on the ſea, which the Latins call *ſalum*: but it is to be obſerved, that this officer had not the ſupreme adminiſtration of naval affairs; that immediately belonged to the dux magnus, or grand general, to whom the admirals were ſubordinate, in quality of Protocomes, firſt count or aſſociate. Others are of opinion, that this word is derived from the Arabic, Emir ol, i. e. great or high lord, and the Greek αλμος, marine; and accordingly we frequently find Emir, in Zonaras, Cedrenus, Nicetas, and other Greeks of that time, uſed in the ſenſe of a commander.

But Sir Henry Spelman, with more reaſon, thinks it paſt doubt that both the name and dignity were derived from the Saracens, and, by reaſon of the holy wars, brought amongſt us; for admiral, in the Arabian language, ſignifies a prince, or chief ruler, and was the ordinary title of the governors of cities, provinces, &c. and that therefore they called the commander of the navy by that name, as a name of dignity and honour. And, indeed, there are no inſtances of admirals in this part of Europe before the year 1284, when Philip of France, who had attended St. Lewis in the wars againſt the Saracens, created an admiral.

Du Cange aſſures us, that the Sicilians were the firſt, and the Genoeſe the next, who gave the denomination of admiral to the commanders of their naval armaments, and that they took it from the Saracen or Arabic Emir, a general name for every commanding officer. As for the exact time when the word was introduced among us, it is uncertain; ſome think it was in the reign of Edward I. Sir Henry Spelman is of opinion that it was firſt uſed in the reign of Henry III. becauſe neither the laws of Oleron, made in 1266, nor Bracton, who wrote about that time, make any mention of it; and that the term admiral was not uſed in a charter in the eighth of Henry III. wherein he granted this office to Richard de Lacey, by theſe words *Maritimam Angliæ*; but in the fifty-ſixth year of the ſame reign, not only the hiſtorians, but the charters themſelves, very frequently uſe the word admiral.

Anciently there were generally three or four admirals appointed in the Engliſh ſeas, all of them holding the office *durante bene placito*; and each of them having particular limits under their charge and government;

as admirals of the fleet of ſhips, from the mouth of the Thames northward, ſouthward, or weſtward.

Beſides theſe, there were admirals of the Cinque ports, as in the reign of Edward III. when one William Latimer was ſtiled *admiralis quinque portuum*; and we ſometimes find that one perſon has been admiral of the fleets to the ſouthward, northward, and weſtward: but the title of *admiralis Angliæ* was not frequent till the reign of Henry IV. when the king's brother had that title given him, which in all commiſſions afterwards was granted to the ſucceeding admirals. It may be obſerved, that there was a title above that of admiral of England, which was, *locum tenens regis ſuper mare*, the king's lieutenant general of the ſea; this title we find mentioned in the reign of Richard II.

Before the uſe of the word admiral was known, the title of *cuſtodes maris* was made uſe of.

Lord high-ADMIRAL *of England*, in ſome ancient records called *capitanus maritimarum*, an officer of great antiquity and truſt, as appears by the laws of Oleron, ſo denominated from the place they were made at by Richard I. The firſt title of admiral of England, expreſsly conferred upon a ſubject, was given by patent of Richard II. to Richard Fitz-allen, jun. earl of Arundel and Surry: for thoſe who before enjoyed this office were ſimply termed admirals, though their juriſdiction ſeems as large, eſpecially in the reign of Edward III. when the court of admiralty was firſt erected.

This great officer has the management of all maritime affairs, and the government of the royal navy, with power of deciſion in all maritime caſes, both civil and criminal: he judges of all things done upon or beyond the ſea, in any part of the world; upon the ſea-coaſts, in all ports and havens, and upon all rivers below the firſt bridge from the ſea. By him, vice-admirals, rear-admirals, and all ſea-captains are commiſſioned; all deputies for particular coaſts, and coroners to view dead bodies found on the ſea-coaſts, or at ſea: he alſo appoints the judges for his court of admiralty, and may impriſon, releaſe, &c.

All ports and havens are *infra corpus comitatus*, and the admiral hath no juriſdiction of any thing done in them. Between high and low water-mark, the common law and the high admiral have juriſdiction by turns, one upon the water, and the other upon the land. The admiral hath power to arreſt ſhips in great ſtreams, and during the ſame voyages, every commanding officer and ſoldier of ſhips of war, ſhall obſerve the commands of the admiral, &c. on pain of death, or other puniſhment.

The lord-admiral has power, not only over the ſeamen ſerving in his ſhips of war, but over all other ſeamen, to arreſt them for the ſervice of the ſtate; and, if any of them run away, without leave of the admiral, he hath power to make a record thereof, and certify the ſame to the ſheriffs, mayors, bailiffs, &c. who ſhall cauſe them to be apprehended and impriſoned.

To the lord high-admiral belong all penalties and amercements of all tranſgreſſions at ſea, on the ſea-ſhore, in ports and havens, and all rivers below the firſt bridge from the ſea; the goods of pirates and felons condemned or enſlaved, ſea-wrecks, goods floating on the ſea, or caſt on the ſhore, (not granted to lords of manors adjoining to the ſea), and a ſhare of lawful prizes; alſo all great fiſhes, commonly called royal fiſhes, except whales and ſturgeons: to which add a ſalary of 7000 l. a year.

It appears that anciently the admirals of England had juriſdiction of all cauſes of merchants and mariners, happening not only upon the main ſea, but in all foreign parts, within the king's dominions, and without them; and were to judge them in a ſummary way, according to the laws of Oleron, and other ſea laws. In the time of Edward I. and king John, all cauſes of merchants and mariners, and things ariſing upon the main ſea, were tried before the lord admiral; by all which, and divers other laws, not only the power of the admiral is declared, but the original from whence it is derived, namely, from the legiſlative power of the parliament, and not from the ſingle perſon of the king, or any other council whatever.

In ſhort, this is ſo great an office, in point of truſt, honour, and profit, that it has uſually been given to princes of the blood, or the moſt eminent perſons among the nobility. We have had no high-admiral for ſome years, the office being put in commiſſion, or under the adminiſtration of the lords commiſſioners of the admiralty, who by ſtatute have the ſame power and authority as the lord high-admiral.

ADMIRAL alſo implies the commander in chief of any ſingle fleet, or ſquadron, or, in general, any flag officer whatever. The commander of a fleet carries his flag at the main-top-maſt head.

Vice ADMIRAL is the commander of the ſecond ſquadron, and carries his flag at the fore-top-maſt head.

Rear ADMIRAL is the commander of the third ſquadron, and carries his flag at the mizzen-top-maſt head.

Vice ADMIRAL is alſo an officer appointed by the lords commiſſioners of the admiralty. There are ſeveral of theſe officers eſtabliſhed in different parts of Great Britain, with judges and marſhals under them, for executing juriſdiction within their reſpective limits. Their decrees however are not final, an appeal lying to the court of admiralty in London.

ADMIRAL is alſo an appellation given to the moſt conſiderable ſhip of a fleet of merchantmen, particularly the veſſels employed in the cod-fiſhery of Newfoundland.

ADMIRAL, in natural hiſtory, is the name of a beautiful ſhell of the voluta kind, greatly admired by the curious.

There are four ſpecies of this ſhell diſtinguiſhed by the names of grand admiral, vice-admiral, orange-admiral, and extra-admiral. The firſt is extremely beautiful, of an elegant white enamel, variegated with bands of yellow, which, in ſome meaſure, repreſent the colours of the flags in ſhips of war. It is of a very curious ſhape, and finely turned about the head; but its diſtinguiſhing character is a denticulated line running along the center of the large yellow band; and this diſtinguiſhes it from the vice-admiral, though the head of the latter is alſo leſs elegantly formed. See plate I. *fig.* 12. where A is the admiral, and B the vice-admiral.

The orange-admiral has more yellow than any of the others, and the bands of the extra-admiral run into one another.

ADMIRALTY properly ſignifies the office of lord high-admiral, whether diſcharged by one ſingle perſon, or by joint commiſſioners, called lords of the admiralty.

Court of ADMIRALTY is a ſovereign court, held by the lord high-admiral, or lords of the admiralty, where cognizance is taken in all maritime affairs, whether civil or criminal.

All crimes committed on the high-ſeas, or on great rivers below the firſt bridge next the ſea, are cognizable in this court only, and before which they muſt be tried by judge and jury. But in civil caſes the mode is different, the deciſions being all made according to the civil law.

ADMIRATION, in grammar, a mark or character importing ſomething wonderful, or worthy of admiration. It is marked thus (!).

The word is Latin, *admiratio*, and compounded of *ad*, at, and *miror*, to wonder.

ADMISSION, among eccleſiaſtical writers, implies the act of a biſhop's admitting, or allowing, a clerk to be able, or properly qualified, for ſerving a cure.

The word is Latin, *admiſſio*, and compounded of *ad*, to, and *mitto*, to ſend.

ADMONITION, in eccleſiaſtical hiſtory, ſignified a part of diſcipline, conſiſting chiefly in warning an offender of the irregularities obſervable in his conduct, and adviſing him to be more careful for the future.

The word is Latin, *admonitio*, and compounded of *ad*, and *monito*, to admoniſh.

ADNATA, in natural hiſtory, is a general name for whatever things grow on animal or vegetable bodies, whether they are inſeparable, as hair, horns, &c. or only aſcititious, as the various epifitical plants.

The word is Latin, and compounded of *ad*, and *nato*, to ſwim or float with.

ADNATA *Tunica*, in anatomy, one of the tunics or coats of the eye, otherwiſe called conjunctiva and albuginea.

It is the ſame part with that termed the white of the eye, and formed by the tendinous expanſions of the muſcles which move that organ. See the article EYE.

ADNATA, or ADNASCENTA, among gardeners, ſignify thoſe off-ſets, which proceed, by a new germination under the earth, from the lilly, narciſſus, hyacinth, and other flowers, and afterwards grow to the roots.

ADNOUN, a term uſed by ſome grammarians to denote the adjective. See the article ADJECTIVE.

The word is formed from the Latin, *adnomen*, and compounded of *ad*, to, and *nomen*, a noun, or name.

AD OCTO, a phraſe uſed, by ancient philoſophers, to imply the higheſt degree of perfection, the eighth being conſidered as the ſummit, or apex.

ADOLESCENCE, the flower of youth, or that part of human life intercepted between infancy and manhood.

The word is Latin, *adoleſcentia*, and derived from *adoleſco*, to grow or increaſe.

ADONAI, one of the names of God, uſed by the ſacred writers.

The word is in the plural number, and properly ſignifies *my lords*.

ADONIA, in antiquity, were feſtivals celebrated in honour of Venus, and in memory of the beloved Adonis. See ADONIS.

ADONAIS, a name given by the ancient botaniſts to the anemony, from an idle ſuppoſition of its having owed its origin to the tears ſhed by Venus, in lamenting the death of her favourite Adonis. See ANEMONY.

ADONIC, a ſort of verſe uſed by the Greek and Latin poets conſiſting of two feet, the firſt of which is a dactyle, and the ſecond a ſpondee, or trochee.

It was originally uſed in the lamentations for the death of Adonis, and from that circumſtance acquired its name. Its principal uſe among the poets, however, is only as a concluſion to the Sapphic verſe; as in the following:

> *Scandit æratas vitioſa naves*
> *Cura, nec turmas equitum relinquit*
> *Ocyor cervis & agente nimbos*
> *Ocyor euro.* HORAT.

ADONIS, in mythology, a pagan divinity, worſhipped in ſeveral places, particularly at Athens, where there were feſtivals inſtituted to him, called Adonia, and at Alexandria, where his image was carried about the city with great ſolemnity. He was a beautiful young ſhepherd, and ſon of Cynaras, king of Cyprus, by his own daughter Myrrha. The goddeſs Venus fell in love with this youth, and often came down to meet him on mount Libanus, where he was at laſt ſlain in the chace of a wild boar.

ADONIS, in zoology, a ſmall fiſh of a cylindrical ſhape, and about ſix inches long, ſuppoſed by Mr. Ray to be the excochis.

ADONIS *Flos*, in botany, a genus of polyandrious plants, called in Engliſh, pheaſant's eye, or red maithers. The leaves reſemble thoſe of fennel, or chamomile; the flower is of the roſaceous kind, or compoſed of ſeveral petals diſpoſed in the form of a roſe; and the ſeeds are contained in oblong capſules.

ADOPTIANS, *Adoptiani*, ancient heretics, the followers of Felix of Urgel, and Elipand of Toledo, who, towards the end of the eighth century, advanced the notion, that Jeſus Chriſt is the ſon of God, not by nature, but by adoption.

ADOPTION, an act by which any one takes another into his family, owns him for his ſon, and appoints him for his heir.

The word is Latin, *adoptio*, and derived from *adopto*, to chuſe.

The cuſtom of adoption was very common among the ancient Romans; yet it was not practiſed, but for certain cauſes expreſſed in the laws, and with certain formalities uſual in ſuch caſes: they firſt learnt it from the Greeks, among whom it was called *Υιοθεσια*.

This adoption was a ſort of imitation of nature, intended for the comfort of thoſe who had no children; wherefore he that was to adopt was to have no children of his own, and to be paſt the age of getting any; nor were eunuchs allowed to adopt, as being under an actual impotency of begetting children; neither was it lawful for a young man to adopt an elder, becauſe that would have been contrary to the order of nature; nay, it was even required that the perſon who adopted ſhould be eighteen years older than his adopted ſon, that there might at leaſt appear a probability of his being the natural father.

ADOPTION, in an eccleſiaſtical ſenſe, is applied to the paſſion of our Saviour, and the communication of the merits of his death, which being applied to us by baptiſm, we become the *adopted* children of God, and have a part in the inheritance of heaven. This is the doctrine taught by St. Paul in ſeveral places, particularly in Rom. viii. 15. Gal. iv. 45.

ADOPTIVE is an epithet applied, in a general ſenſe, to every thing adopted ether by ourſelves, or enjoyed by the conceſſion of another. Thus we ſay, adoptive children, adoptive arms, &c.

ADORATION, a part of worſhip the pagans gave their pretended deities: the poſture for this religious regard was putting their hand to their mouth, and kiſſing it.

The word is Latin, *adoratio*, and compounded of *ad*, to, and *os oris*, the mouth.

Adoration, in the Holy Scriptures, is taken not only for that veneration or worſhip due to God alone, but likewiſe for thoſe marks of outward reſpect which are paid to ſuperiors. Adoration of both kinds is generally attended with bowing the body very low, and ſometimes with proſtration, or throwing one's ſelf on the earth.

The election of popes is performed two ways, by adoration, and by ſcrutiny. In election by adoration, the cardinals ruſh haſtily, as if agitated by ſome ſpirit, to the adoration of ſome one among them, to proclaim him pope. When the election is carried by ſcrutiny, they do not adore the new pope till he is placed on the altar.

ADOSCULATION, a termed uſed, by Dr. Grew, to imply a kind of impregnation, without intromiſſion; and in this manner he ſuppoſes the impregnation of plants is effected by the falling of the farina fœcundans on the piſtil.

ADOSSEE, in heraldry, implies any two animals placed back to back.

AD QUOD DAMNUM, in law, a writ which ought to be iſſued before the king grants certain liberties, as a fair, market, or the like; ordering the ſheriff to enquire what damage is like to be the conſequence of ſuch a grant.

ADRACANTH, the ſame with tragacanth. See the article TRAGACANTH.

ADRACHNE, a name given by ſome botaniſts to a ſpecies of the arbutus, or ſtrawberry-tree. See ARBUTUS.

ADRAMMELECH, in mythology, a deity worſhipped by the inhabitants of Sepharvaim, a people planted in the Holy Land by the kings of Aſſyria, after Salmanazar had taken Samaria, and put a final period to the kingdom of Iſrael. The worſhippers of Adrammelech burnt their children in the fire to the honour of that idol.

It is a Perſian word, and ſignifies, "the magnificent "king."

ADRAMUS, in mythology, is the name of a deity peculiar to Sicily, and was worſhipped in the city of Adram, which thence obtained its name.

ADRASLIA, in antiquity, a kind of Pythian games, celebrated at Argos.

ADRIANISTS, in eccleſiaſtical hiſtory, a ſect of heretics divided into two branches; the firſt were diſciples of Simon Magus, and flouriſhed about the year 34. Theodoret is the only perſon who has preſerved their name and memory; but he gives us no account of their origin. Probably this ſect, and the ſix others which ſprung from the Simonians, took their name from the particular diſciples of Simon. The ſecond were the followers of Adrian Hamſtead, the anabaptiſt, and held ſome particular errors concerning Chriſt. *Bingham's Antiq.*

ADSTRICTION, among phyſicians, implies a too great rigidity and cloſeneſs of the emunctories of the body, particularly in the pores of the ſkin, whereby inſenſible perſpiration is obſtructed.

The word is Latin, *adſtrictio*, and compounded of *ad*, to, and *ſtringo*, to bind.

AD TERMINUM *Qui præteriit*, in law, is a writ of entry which lies for the leſſor or his heirs, if after the expiration of a leaſe, whether it be for years or life, the leſſee, or other occupier of the land, &c. refuſes to quit the premiſes.

ADVANCED, in a general ſenſe, implies ſomething placed or ſituated before another.

ADVANCED *Ditch*, in fortification, is the ditch ſurrounding the glacis or eſplanade of a place.

ADVANCED *Guard*, in military affairs, denotes the firſt line of an army marching towards an enemy. But it is more particularly uſed to ſignify a ſmall party of horſe ſtationed before the main guard.

ADVANCER, among ſportſmen, denotes one of the ſtarts, or branches of a buck's attire, between the back antler and the palm.

ADUAR, a kind of ambulatory village, conſiſting of tents, which the Moors and Arabians move from one place to another as ſuits their conveniency, or the country affords paſture for the cattle and flocks.

ADVENT, a feſtival in the Chriſtian church; being the four Sundays immediately preceding Chriſtmas.

In the Ambroſian office, Advent has ſix weeks, and St. Gregory, in his Sacramentary, allows it five. It is appointed to employ the thoughts of Chriſtians on the firſt Advent, or coming of Chriſt in the fleſh, and his ſecond Advent, or coming to judge the world. The primitive Chriſtians practiſed great auſterity during this ſeaſon. At firſt they faſted three days in the week, but were afterwards obliged to faſt every day.

ADVENTITIOUS, whatever advenes, or is extrinſically added to a body or thing. Thus adventitious matter is that which is joined fortuitouſly to a body.

ADVENTITIOUS, among civilians, implies ſuch goods or effects as are acquired accidentally, or by the liberality of a ſtranger. It alſo ſignifies thoſe effects which a perſon acquires by collateral, not by direct, ſucceſſion.

AD VENTREM *Inſpiciendum*, in law, is a writ commanding a woman to be ſearched, whether ſhe be or be not with child by a former huſband, on her with-holding lands from the heir.

ADVERB, in grammar, is a word joined to a verb, adjective, &c. and ſolely applied to the uſe of qualifying and reſtraining the latitude of their ſignification.

The word is Latin, *adverbium*, and compounded of *ad*, to, and *verbum*, a verb, q. d. a word added to a verb.

Adverbs, though very numerous, may be reduced to certain claſſes, the principal of which are thoſe of order, of place, of time, of quantity, of quality, of manner, of affirmation, of doubting, of compariſon, and of interrogation.

ADVERBIAL, ſomething belonging to adverbs. Thus we ſay, adverbial expreſſions, and adverbial numbers.

ADVERSARIA, a kind of common-place book, uſed by men of letters for entering whatever occurs to them worthy of notice either in reading or converſation.

The word is Latin, and compounded of *ad*, to, and *verto*, to turn.

ADVERSARY, in a general ſenſe, denotes an enemy, or one that oppoſes another.

The word is formed from the Latin prepoſition, *adverſus*, againſt, compounded of *ad*, againſt, and *verto*, to turn.

ADVERSARY, in law, ſignifies either of the contending parties, conſidered as oppoſing each other.

Letter of ADVICE, in commerce, implies a letter ſent by the drawer of a bill of exchange, or the remitter of goods, &c. to his correſpondent, informing him that he has drawn ſuch a bill, or ſent ſuch a quantity of merchandize by ſuch a ſhip, or other conveyance.

No perſon ſhould either accept or pay a bill of exchange without ſuch letter of advice, which ſhould contain the name of the perſon in whoſe favour it is drawn, the date of the bill, and the ſum drawn for.

ADULTERATION, in a general ſenſe, ſignifies the act of debaſing, by ſome improper mixture, ſomething that was pure and genuine.

The word is Latin, *adulteratio*, and derived from *adultero*, to debaſe.

ADULTERATION *of Coin*, is the making it of a baſer metal, or adding a greater proportion of alloy than is uſed in the genuine and ſtandard coin. All nations have conſidered this action as a capital offence.

ADULTERATION, in pharmacy, is the act of uſing ingredients of leſs virtue in a medicinal compoſition, in order to ſave expence. This pernicious practice has greatly impeded the progreſs of the healing art, and too often proved of fatal conſequence to the patient. We wiſh ſuch ungenerous practice, to call it by no harſher name, was baniſhed from the world; but this we fear will never be the caſe, at leaſt till private emolument ſhall be leſs purſued than the good of mankind in general.

ADULTERY, the crime committed by married perſons, whether man or woman, who, in violation of their marriage vow, have carnal commerce with another beſides the perſon to whom they plighted their faith.

The Moſaic law commanded that both the man and the woman who had been guilty of adultery ſhould be put to death.

The Greeks as well as the Romans enacted ſevere laws againſt adulterers. Solon, the wiſe law-giver of the Lacedemonians, made it lawful to kill the adulterer, and enacted that the woman ſhould be puniſhed, by ſtripping her of the ornaments belonging to her quality, by baniſhing her from all religious aſſemblies, and indeed from all ſociety in general. The Thurians had an expreſs law, that perſons guilty of this crime ſhould be repreſented upon the ſtage, and conſequently expoſed to public infamy.

Among the primitive Chriſtians, adulterers were not admitted to the communion till they had done ſeven years penance in faſting and ſackcloth, in ſevere afflictions and ſorrow, according to the diſcipline of thoſe ages.

The Saxons formerly burnt the adultereſs, and erected a gibbet over her aſhes, whereon they hanged the adulterer.

Among the Danes and Saxons in England, the puniſhment of an adulterer was the ſame with that of a murderer. At preſent adultery is conſidered as a ſpiritual offence, and therefore the injured party can only bring his action of damages againſt the adulterer; while all the puniſhment the adultereſs receives is the being divorced from her huſband, and ſtripped of her dower. But perhaps the laying a heavy fine upon the man, and ſtripping the woman of her riches, is a more probable method of preventing the frequency of adultery than more ſevere methods.

ADULTERY, in the language of ſcripture, ſometimes implies idolatry, or the worſhipping of falſe gods.

ADVOCATE, among the Romans, implied a perſon ſkilled in their law, and who undertook the defence of cauſes at the bar.

The word is Latin, *advocatus*, and compounded of *ad*, to, and *voco*, to call; q. d. a perſon called in to the aſſiſtance of another.

The Romans had a very high opinion of the profeſſion of advocates; ſo that the ſeats at their bar were crouded with ſenators and conſuls; and the ſame voices that commanded the people, were alſo employed in defending them. The emperors therefore preferred the gown to the ſword, giving the advocates the title of Comites, Honorati Clariſſimi, and even Patroni, thinking their clients were not leſs obliged to them, than the freedmen were to their maſters for giving them their liberty. But this order in proceſs of time greatly debaſed itſelf, the bar became venal, and the advocates mercenary. The tribune Cynicus, therefore, procured a law to be paſſed, forbidding advocates to take money from their clients; but this was found ineffectual, and the venality of the advocates continued, notwithſtanding the utmoſt efforts of the tribune.

The word advocate is ſtill uſed in countries where the civil law obtains, to imply thoſe who plead the cauſe of clients at the bar. In Scotland there is a college of advocates, conſiſting of one hundred and eighty perſons, appointed to plead all actions before the lords of ſeſſion.

Lord ADVOCATE, one of the officers of ſtate in Scotland, who pleads in all cauſes of the crown, or wherein the king is concerned.

Advocate, in eccleſiaſtical hiſtory, ſignifies a perſon whoſe function it was to defend the laws and revenues of the church and its religious communities.

Conſiſtorial Advocates, are officers of the apoſtolic chamber, who plead in the conſiſtories at Rome.

Fiſcal Advocate, in Roman antiquity, was an officer of ſtate under the Roman emperors, who pleaded in all cauſes wherein the fiſcus or treaſury was concerned.

ADVOWEE, in law, ſignifies the patron of a church, or the perſon who has the right of preſentation to a benefice.

ADVOWSON, in law, the right of patronage, or of preſenting to a vacant benefice.

Advowſons are either appendant or in groſs; the former depend upon, and paſs as appurtenances to a manor or lands; but the latter is a right of preſentation ſubſiſting by itſelf, and belonging to a perſon, without any relation to manors or lands.

In both caſes, however, advowſons are equally the property of the patrons as their landed eſtate; and may accordingly be granted away by deed or will, and become aſſets in the hands of executors.

ADUST, among phyſical writers, is a term applied to ſuch fluids of the human body as are become of a hot and fiery nature.

The word is Latin, *aduſtus*, and compounded of *ad*, and *uro*, to burn.

ADUSTION, in the healing art, implies an inflammation of the parts about the brain and its membranes, attended with a hollowneſs of the eyes, a pale colour, and dryneſs of the body.

ADY, in botany, the name of a ſpecies of palm-tree, found in the iſland of St. Thomas. The fruit reſembles a lemon both in ſize and ſhape, and contains an aromatic kernel, whence an oil is expreſſed, which is uſed inſtead of butter by the inhabitants.

ADYTUM, in antiquity, the moſt retired and ſacred part of the heathen temples, into which none but the prieſts were ſuffered to enter, and from whence oracles were delivered.

The word is Greek, αδυτον, inacceſſible, and compounded of α, priv. and δυνω, or δυω, to enter.

ADZE, a kind of crooked ax uſed by ſhipwrights, coopers, &c.

Æ, among grammarians, a diphthong or double vowel, compoſed of A and E.

Grammarians are not agreed with regard to the uſe of this diphthong in the Engliſh language; ſome being for retaining it in all words where it was uſed by the ancients, and others for laying it totally aſide, and ſupplying its place with the ſingle E. Mr. Johnſon is of the latter opinion, and obſerves, that it ſeems not properly to have any place in the Engliſh alphabet.

ÆACEA, in antiquity, were ſolemn feaſts and games celebrated at Ægina, in honour of Æacus, who, on account of the ſtrict juſtice he diſpenſed upon earth, was feigned to have been appointed one of the judges in hell.

ÆCHMALOTARCH, in antiquity, a title given to the principal leader and governor of the Hebrew captives reſiding in Chaldæa, and the neighbouring countries.

The word is Greek, αιχμαλωταρχης, and compounded of αιχμη, war, and αλωτος, a captive.

The Jews themſelves called this magiſtrate *Roſch-galuth*, chief or prince of the captivity, and pretend that there has always been a continual ſucceſſion of theſe princes, from the time the Hebrews were carried away captive from Judea, to this day. But Baſnage aſſures us, that there was no æchmalotarch before the end of the ſecond century; and Prideaux has ſhewn, that the æchmalotarch, at preſent, is nothing more than the head of their religion, like the epiſcopus Judæorum in England, the alarch at Alexandria, and the ethnarch at Antioch.

ÆDILE, *Ædilis*, among the ancient Romans, implied a magiſtrate, whoſe chief buſineſs conſiſted in ſuperintending edifices of all kinds, eſpecially thoſe which belonged to the public, as temples, aqueducts, bridges, &c.

They had alſo the care of the high-ways, public places, weights, and meaſures. The prices of proviſions were alſo fixed by the ædiles, who likewiſe took cognizance of debauchees, puniſhed lewd women, and ſuch perſons as frequented gaming houſes. They had the cuſtody of the plebiſcita, or orders of the people; inſpected all comedies, and other pieces of wit; and were obliged to exhibit magnificent games to the people at their own expence.

There were originally only two ædiles, who were choſen out of the common people; but perſons of this claſs being unable to ſupport the enormous expence attending their office, two others were created out of the patrician order: theſe took upon themſelves the charges of the games, and were called *ædiles curules*, or *majores*, as the two pelebians were ſtiled *minores*.

Julius Cæſar, in order to eaſe theſe four magiſtrates, increaſed their number to ſix, calling the two additional ones *ædiles cereales*, from their having the inſpection of all manner of grain committed to their care.

ÆGILOPS, in ſurgery, an abſceſs formed in the corner of the eye next the noſe.

The word is Greek, αιγιλωψ, and compounded of αιξ, a goat, and ωψ, an eye; becauſe the patient afflicted with an ægilops has a caſt in the diſeaſed eye, reſembling that of a goat.

In the beginning of this diſorder, a tumour with, and ſometimes without, an inflammation, appears often ſuperficially; but at others ſeated ſo deep, that unleſs the part be preſſed with the finger, it cannot be perceived. The matter contained in this tumour is ſo ſharp and purulent, that it corrodes not only the ſkin, but even the lachrymal ducts, the fat ſeated near the ſinuſes of the eye, and ſometimes the bones called oſſa plana, as well as the adjacent bones of the noſe, frequently cauſing a dangerous caries. Sometimes the inferior and ſuperior lachrymal ducts are ſo totally eroded, that the tears, mixed with the matter, continually flow into the eye, from the puncta lachrymalia, and at laſt cauſe a true fiſtula lachrymalis.

As the inflammation in the ægilops tends rather to ſuppuration than reſolution, the tumour muſt be brought to maturation as ſoon as poſſible, leſt it generate into a troubleſome fiſtula. The applications proper for this purpoſe are emollient cataplaſms, or plaſters of diachylon with the gums. But as ſoon as the matter is known to be formed, the lower part of the tumour ſhould be opened with a knife or lancet, the matter gently preſſed out, and the ulcer carefully deterged and healed in the common manner. If the ulcer breaks ſpontaneouſly, as it often does, and the aperture be ſo ſmall that the matter cannot diſcharge itſelf, it ought immediately to be enlarged with a piece of prepared ſpunge or gentian root, or with the knife. After which it muſt be treated like other ulcers. If the bone be found to be carious, it will be proper to dreſs it with lint dipt in ſpirit of vitriol, or the eſſence of euphorbium. And over the common dreſſings, a compreſs dipt in lime-water muſt be applied, till the caries is removed, and the wound fit for healing. *Heiſter's Surgery.*

ÆGIS, in mythology, implies the ſhield of Jupiter and Pallas, or Minerva.

The word is Greek, αιγις, and derived from αιξ, αιγος, a ſhe-goat; becauſe Jupiter covered his ſhield with the ſkin of Amalthea, the name of the goat that ſuckled him.

It is added that Jupiter, having made a preſent of this buckler to Minerva, the goddeſs fixed the head of Meduſa on the middle of the ſhield, by which means all thoſe who looked on it were turned into ſtone.

ÆGOLETHRON, in botany, the name of a plant which, Pliny ſays, grows in Pontus, and whoſe flowers, in a moiſt ſpring, acquire a poiſonous quality.

The word is Greek, and compounded of αιξ, a goat, and ολεθρος, deſtruction; becauſe it kills thoſe goats which feed upon its leaves.

Tournefort deſcribes a plant by the name of *Chamædodendros Pontica maxima, meſpili folio, flore luteo*, which he takes for the ægolethron of Pliny, and which he found in Aſia. He adds, that the inhabitants of thoſe parts have a tradition, probably founded on repeated obſervations, that the honey which the bees extract from the flowers of this plant, ſtupifies thoſe that eat it, and cauſes a vomiting. This is conformable to what Dioſcorides and Pliny relate of the honey extracted from the ægolethron. We find a ſtrange effect produced by this honey recorded by Xenophon, in his account of the famous retreat of the ten thouſand Greeks under his command. He tells us, that in the neighbourhood of Trebezonde, the ſoldiers finding great plenty of honey, excellent in flavour, eat greedily of it, and were all ſeized with a ſtrange giddineſs, ſome wallowing upon the ground like men dead drunk, while others were ſeized with a kind of phrenzy; ſo that the ground appeared like a field of battle, covered with dying men, every mortal ſymptom appearing in the objects thus affected. Theſe ſymptoms, however, diſappeared in about twenty-four hours, nature throwing off the morbific matter by violent vomitings and purgings.

ÆGYPTIACUM, in pharmacy, the name of a detergent ointment greatly uſed by ſurgeons in cleanſing old and foul ulcers.

It is compounded of verdigriſe, honey, and vinegar, boiled to a proper conſiſtence. Authors are not agreed with regard to the origin of the name. Aetius ſays the appellation was acquired from an Ægyptian phyſician, who uſed a compoſition of this kind, at leaſt one wherein verdigriſe was a principal ingredient, in the cure of an achor. But Dr. Quincy is of opinion, that it owes its name to the colour of the compoſition, which is a duſky brown, reſembling that of the ſkins of the Ægyptians.

Mel ÆGYPTIACUM, the ſcum of the above ointment taken off while the medicine is boiling to a proper conſiſtence: It is of nearly the ſame properties, and uſed in the ſame intentions as the former.

ÆLURUS, in mythology, a deity worſhipped by the ancient Ægyptians, under the form of a cat, or of a man, with the head of that animal.

F. Montfaucon has given a figure of this ancient deity, on the head of which is a large vaſe, crowned with a globe. The head is alſo encircled with rays, it being the cuſtom among that people to repreſent all their deities as having ſome relation to the ſun. They had likewiſe a goddeſs, whom they repreſented under the figure of a woman with the head of a cat.

The Ægyptians had ſo ſuperſtitious a regard for this animal, that the killing it, whether by accident or deſign, was puniſhed with death: and Diodorus relates, that, in the time of extreme famine, they choſe rather to eat one another, than touch theſe ſacred animals.

AEM, or AAM. See AAM.

ÆNIGMA, a dark or perplexed queſtion, in which ſome well known object is concealed under an obſcure deſcription.

The word is Greek, *αινιγμα*, and derived from *αινος*, an obſcure propoſition.

ÆNIGMATICAL, ſomething belonging to, or delivered in, the perplexed manner of an ænigma.

ÆOLIC *Dialect*, among grammarians, one of the five dialects of the Greek tongue, uſed by the inhabitants of Æolia.

ÆOLIC *Verſe*, in proſody, is a verſe conſiſting of an iambus, or ſpondee, then of two anapeſts, ſeparated by a long ſyllable, and laſtly of another ſyllable.

ÆOLIPILE, in hydraulics, is a hollow ball of metal, generally uſed in courſes of experimental philoſophy, in order to ſhew that it is poſſible to convert water into an elaſtic ſteam or vapour, by heat.

The inſtrument, therefore, conſiſts of a ſlender neck, or pipe, having a narrow orifice inſerted into the ball by means of a ſhouldered ſkrew. This pipe, being taken out, the ball is filled almoſt full of water, and the pipe being again ſcrewed in, the ball is placed on a pan of kindled charcoal, where it is well heated, and there iſſues from the orifice a vapour, with prodigious violence and great noiſe, which continues till all the included water is diſcharged. The ſtronger the fire is, the more elaſtic and violent will be the ſteam; but care muſt be taken that the ſmall orifice of the pipe be not, by any accident, ſtopped up; becauſe the inſtrument would in that caſe infallibly burſt in pieces, with ſuch violence as may greatly endanger the lives of the perſons near it.

Another way of introducing the water is to heat the ball red hot when empty, which will drive out almoſt all the air, and then by ſuddenly immerging it in water, the preſſure of the atmoſphere will force in the fluid, till it is nearly full. Some have imagined, that the æolipile may be employed as bellows to blow up a fire, by being heated before it; but experience ſoon convinced them of their miſtake; for they found that the blaſt, inſtead of kindling, totally extinguiſhed the fire.

The body of this inſtrument conſiſts of two parts, A and B (See plate VII. *fig.* 2.) ſoldered together. On the upper part is faſtened the pipe C D, whoſe orifice at D is about one fourth, or one fifth in diameter. Des Cartes and others have uſed this inſtrument to account for the natural cauſe and generation of the wind; and hence it was called *Æolopila*, q. d. *pila Æoli*, the ball of Æolus, or god of the winds. This inſtrument waas not unknown among the ancients; for it is mentioned by Vitruvius, lib. I. cap. 6. F. Merſennus, prop. 29. of his *Phænom. Pneumat.* has alſo mentioned it; and Varenius, in his *Geograph.* cap. xix. uſes it to ſhew the rarefaction of the air by fire.

ÆOLUS, in mythology, the pagan god of the winds. He was the ſon of Hippotas, by Menecla, the daughter of Hyllus, king of Lipara. He dwelt in the iſland Strongyle, one of the ſeven iſlands that are called Æolian, as being all under the dominion of Æolus. Others ſay, that his reſidence was in the iſland Lipara: others again place him at Rhegium, in Italy. But all agree in giving him an abſolute authority over the winds, which they ſay he confined in a vaſt cavern, and let looſe whenever he pleaſed.

Harp of ÆOLUS, a muſical inſtrument, ſo contrived that, being properly placed in a current of air, emitted thro' an aperture in the window of an apartment, produces admirable muſic merely by the wind playing on the ſtrings. This inſtrument is mentioned by father Kircher; but owes its perfection to Mr. Oſwald of London.

ÆON, a Greek word, properly ſignifying the age or duration of any thing.

ÆON, among the followers of Plato, was uſed to ſignity any virtue, attribute, or perfection; and hence they repreſented the Deity as an aſſemblage of all poſſible æons, and called him pleroma, a Greek term, ſignifying fullneſs.

The Valentinians, who, in the firſt ages of the church, blended the conceits of the Jewiſh cabaliſts, the Platoniſts, and the Chaldean philoſophers, with the ſimplicity of the Chriſtian doctrine, invented a kind of Theogony, calling the ſelf originated Deity, or God the father, by the names of *Bythus*, i. e. profound or unfathomable; and "the "moſt high and ineffable father:" and the ſeveral ſubordinate deities, by different appellations; but included all under the general name of æons. See the article VALENTINIANS.

ÆQUATION.	See	EQUATION.
ÆQUATOR.		EQUATOR.
ÆQUINOX.		EQUINOX.
ÆQUINOCTIAL.		EQUINOCTIAL.

ÆRA, in chronology, is a fixed point of time from which chronologers reckon. Æras are either Chriſtian, Jewiſh, Heathen, or Mahometan. Chriſtian æras are deduced either from the birth of Chriſt, from the emperor Diocleſian, or the beginning of the world. Chronologers differ as to the true point of time in which Chriſt was born: ſome place it two years, others four, and ſome five, before the vulgar æra, which is that in general uſed among the Chriſtians.—For the different æras, or epochas, uſed by chronologers, ſee the article EPOCHA.

AERIAL, an epithet applied to every thing partaking of the nature of air, or that is connected with, or belongs to, the air.

The word is formed from the Greek, *αηρ*, air.

AERIAL *Tides*. See TIDES.

AERIANS, in eccleſiaſtical hiſtory, a ſect of heretics who ſeparated themſelves from the church party in the reign of Conſtantine the Great, and during the pontificate of Julius I. about the year 342. They had their name from one Aerius, a preſbyter, who, thinking himſelf neglected by not being advanced to the dignity of a biſhop, went over to the Arian party; but held ſome opinions peculiar to himſelf, as, that there was no diſtinction, founded in Scripture, between preſbyter and biſhop. He alſo aſſerted that we are not obliged to obſerve the ſtated feaſts of the church, admitted thoſe only into his ſect who lived in continence, and condemned marriage as unlawful.

AEROGRAPHY, a deſcription of the air.

The word is Greek, and compounded of αηρ, air, and γραφω, to deſcribe.

AEROLOGY, an account of the nature and properties of the air.

The word is Greek, and compounded of αηρ, air, and λογος, a diſcourſe.

AEROLOGICE, among phyſicians, implies that part of medicine which relates to the air, its properties, and uſes in the animal œconomy, and its efficacy in preſerving and reſtoring health.

AEROMANCY, a ſpecies of divination among the ancients, performed by obſerving the air, winds, &c.

The word is Greek, and compounded of αηρ, air, and μαντεια, divination.

AEROMANCY, is alſo uſed by ſome writers to ſignify the art of foretelling the various changes of the air and weather, by means of barometers, hydrometers, thermometers, &c.

AEROMETRY, the ſcience of meaſuring the air.

The word is Greek, and compounded of αηρ, air, and μετρεω, to meaſure. It comprehends not only the doctrine of the air itſelf, conſidered as a fluid body, but alſo its preſſure, elaſticity, rarefaction, and condenſation. See ELASTICITY, RAREFACTION, and CONDENSATION.

The term is at preſent not much in uſe, this branch of natural philoſophy being more frequently called pneumatics. See PNEUMATICS.

Baron Wolfius, late profeſſor of mathematics at Hall, having reduced ſeveral properties of the air to geometrical demonſtrations, firſt publiſhed at Leipſic, his Elements of Aerometry in German, and afterwards more enlarged in Latin, which have been ſince inſerted in his *Curſus Mathematicus,* in five vols. in 4to.

ÆRUGINOUS, an epithet applied to ſuch particulars as reſemble ærugo, or the ruſt of copper, either with regard to taſte or colour.

ÆRUGO, in natural hiſtory, properly ſignifies the ruſt of copper, whether natural or artificial. The former is found about copper mines, and the latter made by corroding copper plates with acids. See the article VERDIGRISE.

ÆS, in natural hiſtory, ſignifies copper. It is alſo uſed for money coined of that metal.

ÆS, ÆSCULANUS, or ÆRES, in mythology, the deity who preſides over the coinage of copper money. He is repreſented with a ſceptre in his left hand, and a balance in his right.

ÆS *Uſtum*, a chemical preparation, made of thin leaves of copper, ſulphur, and nitre, placed *ſtratum ſuper ſtratum* in a crucible, and ſet in a charcoal fire, till all the ſulphur is conſumed; after which, the copper is taken out of the crucible and reduced to powder. Some quench the leaves of copper in vinegar, and repeat the calcination.

Its principal uſe is in colouring glaſs, to which it gives a beautiful tincture. The ſurgeons uſe it as a deterſive; and ſome have given it internally; but it is certainly a very dangerous medicine, and ſhould be avoided.

ÆSALON, in natural hiſtory, a ſpecies of long-winged-hawk, generally called, in Engliſh, the merlin. See MERLIN.

ÆSCHNA, in natural hiſtory, the name of a four-winged water-fly, with a long body, hairy near the tail.

ÆSCHYNOMENOUS, an epithet ſometimes applied to a genus of vegetables, generally called ſenſitive plants, which contract their leaves on the approach of the hand, as if ſenſible of the touch.

The word is Greek, αισχυνομενος, and derived from αισχυνομαι, to be aſhamed.

ÆSCULANUS, in mythology. See ÆS.

ÆSCULAPIUS, in mythology, the god of phyſic. The poets ſay he was ſon of Apollo, by the nymph Coronis; who, afterwards favouring a Thracian youth, named Iſchys, was ſtruck through with darts by Apollo: but he, repenting the action, opened her womb, and, taking out the child, called him Æſculapius, and committed the care of his education to Chiron.

Snake of ÆSCULAPIUS, *Anguis Æſculapii,* in natural hiſtory, is a harmleſs kind of a ſerpent, of an oblong ſhape, an ell in length, and of a yellowiſh, or rather porraceous, colour, except on the back, where it is brown. Both jaws are armed with many very ſharp teeth, and on the neck are two ſmall eminences. Theſe ſerpents are very common in Spain, Italy, and other warm countries.

Seba has mentioned the following ſeven ſorts of æſculapian ſerpents: the firſt has the whole body encircled from the head to the tail, with broad brown and black ſtreaks; and the ſcales that cover the body are of an aſh colour, and grey, mixed with white.

The Braſil ſerpent, variegated with divers colours, is defended with ſtrong ſcales of a dull blue colour, mixed with black, and finely undulated. The head is curiouſly mottled and ſpeckled, and the tranſverſe ſcales on the belly are moſtly white.

The æſculapian ſerpent of Panama in America has a bluiſh violet coloured body, and the belly is of a paler blue, with tranſverſe large white ſcales, joined cloſe together, except at the bending of the back, where they are all ſeparated. The head is covered with long broad uniform ſcales. The mouth is armed with ſharp crooked teeth; and it lives upon mice and ſmall birds. Its excrements ſmell like muſk.

The argoli is an American ſerpent, of the æſculapian kind. The ſcales are rhomboidal, and of a greyiſh black, with large bay brown ſpots, ſome of which are round, and others oblong; but the belly is whitiſh, and the tail terminates in a point.

Another ſpecies of argoli is of the ſame kind. Its ſcales are of a whitiſh aſh colour, diſpoſed in a beautiful manner, and more exactly than in the former. The tail is blunt at the end, and the head and eyes ſhining, and fiery.

The æſculapian ſerpent of Braſil is near three ells in length, with the head covered with large beautiful ſcales, and the neck ſurrounded by a narrow collar. The ſcales on the body are white, and in the ſhape of lozenges, each being marked in the middle with a ſmall black furrow. From the neck to the tail there are large red and brown ſpots, which are longiſh near the head, and ſhorter as they approach to the tail. The mouth is armed with very ſmall teeth.

The æſculapian ſerpent, of the Eaſt-Indies, is very large, and the upper part of the body is covered with yellow ſcales, ſhaded with duſky brown, and ſhine remarkably. It is encircled with bay brown ſtreaks, ſome of which are narrow, others broad. The ſcales on the ſides, and under the belly, are of a yellowiſh aſh colour; the head is little, ſhort, and prettily variegated with black and brown; the forehead is marked with two whitiſh ſpots, and the neck is ſurrounded with a white ring. The teeth are very ſmall, the body is round and fleſhy, and the tail blunt. *Brookes's Natural Hiſt.*

ÆSNECY, in law, ſignifies the priority of age among coparceners. See COPARCENERS.

ÆSTIVAL, ſomething belonging to, or connected with, the ſummer. Thus the æſtival ſolſtice is the ſame with the ſummer ſolſtice.

The word is Latin, *æſtivus,* and derived from *æſtas,* ſummer.

ÆSTUARY, in geography, implies an arm of the ſea, running a conſiderable way into the land.

The word is Latin, *æſtuarium,* and derived from *æſtus,* a tide or eddy, there being generally very ſtrong tides in theſe inlets.

ÆSTUARY, among phyſicians, implies a vapour-bath, or any other contrivance for conveying heat to the whole, or any particular part of the body.

The word in this ſenſe is derived from *æſtus,* heat.

ÆTHER, in philoſophy, a very thin elaſtic fluid, readily pervading the pores of all bodies, and expanded through every part of ſpace.

The word is Greek, αιθηρ, and derived from αιθω, to burn; becauſe the ancient philoſophers ſuppoſed it to be of the nature of fire.

Philoſophers have always been greatly divided in their opinions, with regard to this ſubtile fluid; and ſome have even queſtioned its exiſtence. The following account of the æther is taken from Sir *Iſaac Newton*'s Optics, where that great philoſopher has delivered his ſentiments in a ſeries of queſtions or queries.

If in two large tall cylindrical veſſels of glaſs inverted, two little thermometers be ſuſpended ſo as not to touch the veſſels, and theſe veſſels, thus prepared, be carried out of a cold place into a warm one; the thermometer in vacuo will grow warm as much, and almoſt as ſoon, as the thermometer which is not in vacuo; and, when the veſſels are carried back into the cold place, the thermometer in vacuo will grow cold almoſt as ſoon as the other thermometer. Is not the heat of the warm room conveyed through the vacuum by the vibrations of a much ſubtiler medium than air, which after the air was drawn out remained in the vacuum? And is not this medium the ſame with that medium by which light is refracted and reflected, and by whoſe vibrations light communicates heat to bodies, and is put into fits of eaſy reflexion and eaſy tranſmiſſion? And do not the vibrations of this medium, in hot bodies, contribute to the intenſeneſs and duration of their heat? And do not hot bodies communicate their heat to contiguous cold ones, by the vibrations of this medium propagated from them into the cold ones? And is not this medium exceedingly more rare and ſubtile than the air, and exceedingly more elaſtic and active? And doth it not readily pervade all bodies? And is it not, by its elaſtic force, expanded through all the heavens?

Does not the refraction of light proceed from the different denſity of this ætherial medium in different places, the light receding always from the denſer parts of the medium? And is not the denſity thereof greater in free and open ſpaces, void of air and other groſſer bodies, than within the pores of water, glaſs, cryſtal, gems, and other compact bodies? For when light paſſes through glaſs or cryſtal, and falling very obliquely upon the farther ſurface thereof, is totally reflected, the total reflexion ought to proceed rather from the denſity and vigour of the medium without and beyond the glaſs, than from the rarity and weakneſs thereof.

Doth not this ætherial medium, in paſſing out of water, glaſs, cryſtal, and other compact and denſe bodies into empty ſpaces, grow denſer and denſer by degrees, and by that means refract the rays of light, not in a point, but by bending them gradually in curve lines? And doth not the gradual condenſation of this medium extend to ſome diſtance from the bodies, and thereby cauſe the inflexions of the rays of light which paſs by the edges of denſe bodies, at ſome diſtance from the bodies?

Is not this medium much rarer within the denſe bodies of the ſun, ſtars, planets, and comets, than in the empty celeſtial ſpaces between them? And in paſſing from them to great diſtances, doth it not grow denſer and denſer perpetually, and thereby cauſe the gravity of thoſe great bodies towards one another, and of their parts towards the bodies; every body endeavouring to go from the denſer parts of the medium towards the rarer? For if this medium be rarer within the ſun's body than at its ſurface, and rarer there than at the hundredth part of an inch from its body, and rarer there than at the fiftieth part of an inch from its body, and rarer there than at the orb of Saturn; I ſee no reaſon why the increaſe of denſity ſhould ſtop any where, and not rather be continued through all diſtances from the ſun to Saturn, and beyond. And though this increaſe of denſity may at great diſtances be exceeding ſlow, yet, if the elaſtic force of this medium be exceeding great, it may ſuffice to impel bodies from the denſer parts of the medium towards the rarer, with all that power which we call gravity: and that the elaſtic force of this medium is exceeding great, may be gathered from the ſwiftneſs of its vibrations. Sounds move about 1140 Engliſh feet in a ſecond of a minute of time, and in ſeven or eight minutes of time, they move about 100 Engliſh miles. Light moves from the ſun to us in about ſeven or eight minutes of time, which diſtance is about 70000000 Engliſh miles, ſuppoſing the horizontal parallax of the ſun to be about 12″. And the vibrations or pulſes of this medium, that they may cauſe the alternate fits of eaſy tranſmiſſion and eaſy reflection, muſt be ſwift than light, and by conſequence above 700000 times ſwifter than ſounds; and therefore the elaſtic force of this medium, in proportion to its denſity, muſt be above 700000 × 700000 (that is, above 490000000000) times greater than the elaſtic force of the air is in proportion to its denſity. For the velocities of the pulſes of elaſtic mediums are in a ſubduplicate ratio of the elaſticities and the rarities of the mediums, taken together.

As attraction is ſtronger in ſmall magnets than in great ones, in proportion to their bulk; and gravity is greater in the ſurfaces of ſmall planets than in thoſe of great ones, in proportion to their bulk; and ſmall bodies are agitated much more by electric attraction than great ones; ſo the ſmallneſs of the rays of light may contribute very much to the power of the agent, by which they are refracted. And ſo, if any one ſhould ſuppoſe that æther (like our air) may contain particles which endeavour to recede from one another (for I do not know what this æther is), and that its particles are exceedingly ſmaller than thoſe of air, or even than thoſe of light, the exceeding ſmallneſs of its particles may contribute to the greatneſs of the force, by which thoſe particles may recede from one another, and thereby make that medium exceedingly more rare and elaſtic than air, and by conſequence exceedingly leſs able to reſiſt the motions of projectiles, and exceedingly more able to preſs upon groſs bodies, by endeavouring to expand itſelf.

May not the planets and comets, and all groſs bodies, perform their motions more freely, and with leſs reſiſtance in this ætherial medium than in any fluid, which fills all ſpace adequately without leaving any pores, and by conſequence is much denſer than quick-ſilver or gold? And may not its reſiſtance be ſo ſmall, as to be inconſiderable? For inſtance; if this æther (for ſo I will call it) ſhould be ſuppoſed 700000 times more elaſtic than our air, and above 700000 times more rare, its reſiſtance would be above 600000000 times leſs than that of water: and ſo ſmall a reſiſtance would ſcarce make any ſenſible alteration in the motions of the planets in ten thouſand years. If any one would aſk how a medium can be ſo rare, let him tell me how the air, in the upper parts of the atmoſphere, can be above an hundred thouſand thouſand times rarer than gold. Let him alſo tell me how an electric body can, by friction, emit an exhalation ſo rare and ſubtile, and yet ſo potent, as by its emiſſion to cauſe ſo ſenſible diminution of the weight of the electric body, and to be expanded through a ſphere, whoſe diameter is above two feet, and yet to be able to agitate and carry up leaf copper, or leaf gold, at the diſtance of above a foot from the electric body? And how the effluvia of a magnet can be ſo rare and ſubtile, as to paſs through a plate of glaſs without any reſiſtance or diminution of their force, and yet ſo potent as to turn a magnetic needle beyond the glaſs?

Is not viſion performed chiefly by the vibrations of this medium, excited in the bottom of the eye by the rays of light, and propagated through the ſolid, pellucid and uniform capillamenta of the optic nerves into the place of ſenſation? And is not hearing performed by the vibrations either of this or ſome other medium, excited in the auditory nerves by the tremors of the air, and propagated through the ſolid, pellucid and uniform capillamenta of thoſe nerves into the place of ſenſation? And ſo of the other ſenſes.

Is not animal motion, performed by the vibrations of this medium, excited in the brain by the power of the will, and propagated from thence through the ſolid, pellucid, and uniform capillamenta of the nerves into the muſcles, for contracting and dilating them? I ſuppoſe that the capillamenta of the nerves are each of them ſolid and uniform, that the vibrating motion of the ætherial medium may be propagated along them from one end to the other uniformly, and without interruption; for obſtructions in the nerves create palſies. And that they may be ſufficiently uniform, I ſuppoſe them to be pellucid when viewed ſingly, though the reflexions in their cylindrical ſurfaces may make the whole nerve (compoſed of many capillamenta) appear opake and white, for opacity ariſes from reflecting ſurfaces, ſuch as may diſturb and interrupt the motions of this medium.

Æther, in chemiſtry, ſignifies a very remarkable fluid, lighter, more volatile, and more inflammable, than the moſt highly rectified ſpirit of wine. It quickly flies off when expoſed to the air, and ſuddenly catches fire when any flame approaches it. It burns like ſpirit of wine, without the leaſt ſmoke, and conſumes entirely, without leaving the ſmalleſt appearance of a coal or of aſhes. It diſſolves oils, and oily matters, with great eaſe and rapidity. Theſe properties it has in common with an ardent ſpirit: but it reſembles an oil in that it is not miſcible with water; and this makes it eſſentially different from ſpirit of wine, the nature of which is to be miſcible with all aqueous liquors.

Another very ſingular property of æther is its great affinity with gold, exceeding even that of aqua regis. It does not indeed diſſolve gold when in a maſs, and in its metalline form: but if a ſmall quantity of æther be added to a ſolution of gold, in aqua regis, and the whole ſhaken together, the gold ſeparates from the aqua regis, joins the æther, and remains diſſolved therein.—The following method of making this æthereal fluid, will be found both eaſy and expeditious.

Put into a glaſs retort, two pounds of ſpirit of wine, perfectly dephlegmated, and pour on it at once two pounds of highly concentrated oil of vitriol: ſhake the retort gently ſeveral times, in order to mix the two liquors. This will produce an ebullition, and conſiderable heat; vapours will aſcend with a pretty loud hiſſing noiſe, which will diffuſe a very aromatic ſmell, and the mixture will be of a deeper or lighter red colour, according as the ſpirit of wine was more or leſs oily. Set the retort on a ſand bath, made nearly as hot as the liquor, lute on a tubulated ballon, or large globular receiver, and diſtil the mixture with a fire ſtrong enough to keep the liquor always boiling; a very aromatic ſpirit of wine will firſt come over into the ballon, after which the æther will riſe. When about five or ſix ounces of it are come off, you will ſee, in the upper concavity of the retort, a vaſt number of little points in a veined form, which will appear fixed, and which are nevertheleſs ſo many little drops of æther, rolling over one another, and trickling down into the receiver. Theſe little points continue to appear and ſucceed each other to the end of the operation. Keep up the ſame degree of fire, till, upon opening the little hole in the ballon, you perceive that the vapours, which inſtantly fill the receiver, have the ſuffocating ſmell of volatile ſpirit of ſulphur.

Then unlute the receiver, pour the liquor it contains into a chryſtal bottle, and ſtop it cloſe: there will be about eighteen ounces of it; lute on your receiver again, and continue the diſtillation with a greater degree of fire. There will come over an aqueous, acid liquor, ſmelling ſtrong of a ſulphureous ſpirit, which is not inflammable. It will be accompanied with undulating vapours, which being condenſed, will form an oil, moſt commonly yellow, one part of which will float on the ſurface of the liquor, and another will ſink to the bottom.

Towards the end of the diſtillation of this acid liquor, and of the yellow oil of which it is the vehicle, that part of the mixture which is left in the retort, and grown black, will begin to riſe in froth: then ſuppreſs your fire at once, ſtop the diſtillation, and change your receiver once more. When the veſſels are grown pretty cool, finiſh your diſtillation with a lamp-heat kept up for twelve or fifteen days, which, in all that time, will raiſe but a very little ſulphureous ſpirit. Then break your retort, in which you will find a black ſolid maſs, like a bitumen. It will have an acid taſte, ariſing from a remainder of the acid imperfectly combined with oil.

This artificial bitumen may be freed from its redundant acid, by waſhing it in ſeveral waters. Then put it into a glaſs retort, and diſtil it with a ſtrong reverberated fire; you will obtain a reddiſh oil that will ſwim on water, much like the oil obtained by diſtilling the natural bitumens. This oil alſo will be accompanied with an aqueous acid liquor. In the retort will be left a charred matter, which, being put into an ignited crucible in the fire, burns for ſome time, and, when well calcined, leaves a white earth.

The liquors that riſe firſt in this diſtillation, and which we directed to be kept by themſelves, are a mixture; 1. of highly dephlegmated ſpirit of wine, of a moſt fragrant ſmell; 2. of æther, which the ſpirit of wine wherewith it is united, renders miſcible with water; 3. of a portion of oil, which commonly riſes with æther towards the end of the operation; 4. and ſometimes of a little ſulphureous acid, if the receiver be not changed ſoon enough.

In order to ſeparate the æther from theſe other ſubſtances, put the whole into a retort, with a little oil of tartar per deliquium to abſorb the ſulphureous acid, and diſtil very ſlowly in a ſand-bath heated by a lamp, till near half the liquor be come over. Then ceaſe diſtilling: put the liquor in the receiver into a phial with ſome water, and ſhake it; you will ſee it riſe with rapidity to the upper part of the phial, and float on the ſurface of the water: this is the æther, and muſt be poured off, and kept in a bottle with a glaſs ſtopper accurately ground.

Mr. Hellot, in a memoir delivered to the Academy of Sciences, has given the following proceſs for preparing æther; by means whereof, by the help of an earthy medium, it is eaſy to diſtil the vinous acid ſpirit containing the æther, without any ſenſible change of ſmell, from the beginning to the end of the operation; without its being ſucceeded by an acid ſulphureous liquor, oil, black ſcum, reſin, or bitumen; and without the neceſſity of taking any great care about the management of the fire, as the liquor may always be kept boiling in the retort, and diſtilled to dryneſs without any danger. This medium is common potter's earth. Mr. Hellot puts ſix ounces thereof, well dried and pulverized, into a large retort, with one pound of ſpirit of wine and eight ounces of vitriol. Theſe he digeſts together three or four days. The mixture acquires no ſenſible colour. He ſets the retort in a ſand-bath, and continues the diſtillation to dryneſs with a moderate charcoal fire. Excepting a few drops that riſe firſt, and which are pure ſpirit of wine, all the reſt of the liquor that diſtils hath conſtantly the ſmell of æther; which is even ſomewhat more penetrating than that of the vinous acid ſpirit obtained without the intervention of the earthy medium.

We have ſeen that the production of the æthereal liquor is owing to a ſemi-decompoſition of the ſpirit of wine, effected by the vitriolic acid during the diſtillation: that this acid continuing to act, produces a total decompoſition, or perfect ſeparation of the oil and phlegm of the ſpirit of wine from each other; and that the vitriolic acid, uniting with theſe two principles, forms the ſulphureous phlegm, the fluid oil, and the bituminous matter, all frequently mentioned above. Why then, in this experiment of Mr. Hellot's, do we obtain only a ſpirit of wine replete with æther, while none of the other productions appear? The reaſon is a very natural one, and very clear: it is this; the potter's clay containing an earth of that kind which we call abſorbent, becauſe it poſſeſſes the property of uniting with acids, that earth joins with the vitriolic acid in the mixture, reduces it to a neutral ſalt, and thereby prevents its continuing to act upon the ſpirit of wine, as is neceſſary to the total decompoſition thereof. Mr. Hellot ſays, on this occaſion, “ That part of the vitriolic acid turning its action on this “ ſoluble earth or bole, which it finds in the potter's “ clay, ceaſes to act on the inflammable principle of “ the ſpirit of wine; that, conſequently, as there is not “ an immediate and continuous combination of theſe two “ ſubſtances, neither a reſin nor a bitumen can reſult “ therefrom. This is ſo true, that a great part of the oil “ of vitriol may be afterwards recovered from the pot- “ ter's clay, as colourleſs as when it was firſt uſed.”

Mr. Hellot makes uſe of the following method for procuring the æther from the acid vinous ſpirit obtained by this diſtillation. “ You muſt, ſays he, put all this “ liquor into a glaſs body, made of one piece, with its “ head; pour upon it, through the hole in the upper “ part of the head, twice or thrice as much well-water, “ the hardeſt to the taſte, and the moſt impregnated “ with gypſum, that can be got. Very pure water, he “ obſerves, produces much leſs æther.

“ If the vinous acid ſpirit have ſuch a ſulphureous “ ſmell, as to occaſion a ſuſpicion that it contains a “little too much of a volatile [vitriolic acid, you muſt add to the water two or three drams of ſalt of tartar, or potaſh to abſorb that acid; and then diſtil with a lamp-heat.

“While any true æther remains in the mixture, you will ſee it aſcend like a white pillar iſſuing from the midſt of the liquor, and conſiſting of an infinite number of air-bubbles inexpreſſibly ſmall. Nothing ſeems to condenſe in the cavity of the head, which always remains clear, without any viſible humidity. The drops which light on the ſides of the receiver, inſtead of forming a net-work thereon, as ſpirit of wine doth when it is a little aqueous, ſpread to the breadth of two inches or more, when they conſiſt of true æther.

“As ſoon as you perceive this track begin to grow conſiderably narrower, the fire muſt be put out: for what riſes afterwards will be mixed with water, and communicate that fault to the æther already collected in the receiver.

“Then pour this ætherial liquor into a long bottle, and add to it an equal quantity of well-water. Shake the bottle; the liquor will become milky, and the true æther will inſtantly ſeparate, float upon the water, and mix no more with it. Separate it then by a ſiphon, and keep it in a glaſs-bottle ſhut cloſe with a glaſs ſtopple.”

ÆTHERIAL, ſomething belonging to, or partaking of, the nature of æther.

ÆTHERIAL *Oil*, among chemiſts, a ſubtile, eſſential oil, approaching to the nature of ſpirit.

ÆTHIOPIAN *Crown*, in natural hiſtory, the name of a curious ſhell, about three inches in length, and two in breadth; of an oval ſhape. The mouth is long and wide, and cleaves the extremity of the ſhell a little way. The clavicle is ſhort and blunt at the end, and has four turns; that next the body, as well as the upper edge of the body itſelf, are deeply dentated, or, as ſome ſay, crowned; and the teeth are formed into regular, even, conical points. The ſurface is pretty ſmooth, except a few impreſſions of longitudinal lines, and of a pale, browniſh yellow. It is brought from Africa and the Eaſt Indies. *Brookes's Natural Hiſt.*

ÆTHIOPS *Mineral*, in pharmacy, a preparation of mercury, made by rubbing in a glaſs, marble, or iron mortar, equal quantities of quick-ſilver and flowers of ſulphur, till the mercury wholly diſappears, and the whole becomes a black powder.

This is eſteemed one of the ſafeſt preparations of mercury, and is greatly uſed againſt foulneſſes of the ſkin, in ſcrophulous caſes, and in obſtinate venereal caſes. It has been long known as a remedy againſt worms, and is given with great ſucceſs in that complaint. Its doſe is from a ſcruple to a dram.

ÆTHIOPS *of Antimony*, a powerful medicine recommended by Dr. Cockburn, and prepared in the following manner:

Flux equal parts of antimony and ſea-ſalt in a crucible for an hour. When the matter is cold, break the crucible, and knock the ſcoria from the regulus. Then take equal parts of mercury and this regulus, and rub them together till they are incorporated.

This is a very powerful medicine, and will remove moſt chronical diſorders of the ſkin; and is of great ſervice in all kinds of obſtructions. Hence it becomes ſerviceable in the king's evil, and moſt diſeaſes of the glands.

AETIANS, in eccleſiaſtical hiſtory, a ſect of heretics that appeared during the reign of Conſtantius, and in the pontificate of Liberius, about the year 336. They had their name from one Aetius, a Syrian; who, being reduced to poverty by the confiſcation of his paternal eſtate, ſet up the trade of a goldſmith; but ſoon after, quitting that employment, applied himſelf to ſtudy, and became a very ſubtle diſputant. He firſt ſettled at Antioch, but, being driven from that city, he hired himſelf, as a menial ſervant, to a certain ſophiſt, at Anabarzus, a city of Cilicia, of whom he learned grammar and logic: but, quarrelling with his maſter about his opinions, he went to Tarſus, and applied himſelf to the ſtudy of divinity. From thence he returned to Antioch, but, being again expelled for the impiety of his opinions, he undertook the practice of phyſic, which he continued till Leontius was promoted to the ſee of Antioch, when that prelate appointed him deacon of his own church; where he continued for ſome time, but afterwards repaired to Alexandria, and oppoſed Athanaſius, openly embracing the party of the Arians.

But, beſides the opinions which the Aetians held in common with the Arians, they maintained, that faith, without works, was ſufficient to ſalvation; and that no ſin, however grievous, would be imputed to the faithful. Aetius likewiſe affirmed, that what God had concealed from the Apoſtles, he had revealed to him.

ÆTIOLOGY, in phyſic, is that branch of the healing art which aſſigns the cauſes of diſeaſes.

The word is Greek, αιτιολογια, and compounded of αιτια, cauſe, and λογος, a diſcourſe.

ÆTITES, the eagle-ſtone, in natural hiſtory, a general name for all pebbles or ſtones of any kind, that have a looſe nucleus rattling within.

The word is Greek, αετιτης, and derived from αετος, an eagle; becauſe the ancients ſuppoſed it was found in the eagle's neſt.

There are a great variety of theſe ſtones; but the moſt valued are thoſe formed from the ſeveral varieties of our pebbles. See plate I. *fig.* 11. which repreſents a ſection of the eagle-ſtone, in order to ſhew the cavity and nucleus.

Many virtues have been aſcribed to the ætites by the ancients; but they are all now conſidered as fabulous, and accordingly it has now no place in the materia medica.

AFFECTION, in a general ſenſe, implies an attribute inſeparable from its ſubject. Thus magnitude, figure, weight, &c. are affections of all bodies; and love, fear, hatred, &c. are affections of the mind.

AFFECTION, among phyſicians, ſignifies the ſame as diſeaſe. Thus the hyſteric affection is the ſame with the hyſteric diſeaſe.

AFFEERERS, or AFFEERORS, in law, are perſons appointed in court-leets, courts-baron, &c. to ſettle upon oath the fines proper to be impoſed upon thoſe who have been guilty of faults puniſhable in thoſe courts.

AFFECTUOSO, or *Con* AFFECTO, in the Italian muſic, ſignifies that the part to which it is added, ought to be played in a very tender and moving manner.

AFFIANCE, in law, denotes the mutual plighting of troth between a man and woman, to marry each other.

AFFIDAVIT, in law, ſignifies an oath, in writing, ſworn before ſome perſon properly authoriſed.

The principal uſe of affidavits is to ſatisfy the ſerving proceſſes, or other matters, concerning the proceedings in a court; and ſhould therefore relate only to the matter of fact to be proved, without taking any notice of the merits of the cauſe. But the true place of habitation, and true addition of every perſon who ſhall make an affidavit, muſt be inſerted in it.

AFFINITY, among civilians, implies a relation contracted by marriage; in contradiſtinction to conſanguinity, or relation by blood.

The word is formed from the Latin, *affinitas*, compounded of *ad*, to, and *finis*, boundary; becauſe the limit or boundary of one family approaches to that of another.

AFFINITY, in chemiſtry, implies that natural impulſe or attraction which various bodies exert towards each other.

All the experiments hitherto made, concur with daily obſervation to prove that different bodies, whether principles or compounds, have ſuch a mutual conformity, relation, affinity, or attraction, as diſpoſes ſome of them to join and unite together, while they are incapable of contracting any union with others. This effect, from whatever cauſe it flows, enables the chemiſt to account for, and connect together, all the phænomena that his art produces; and we will endeavour to diſplay the nature of this univerſal affection of matter in the following propoſitions.

Firſt, If one ſubſtance has any affinity or conformity with another, the two will unite together, and form one compound.

Secondly, It may be laid down as a general rule, that all ſimilar ſubſtances have an affinity with each other, and are conſequently diſpoſed to unite; as water with water, earth with earth, &c.

Thirdly, Subſtances that unite together loſe ſome of their ſeparate properties; and the compounds reſulting from their union partake of the properties of thoſe ſubſtances, which ſerve as their principles.

Fourthly, The ſimpler any ſubſtances are, the more perceptible and conſiderable are their affinities: whence it follows, that the leſs bodies are compounded, the more difficult it is to analyſe them; that is, to ſeparate from each other the principles of which they conſiſt.

Fifthly, If a body conſiſt of two ſubſtances, and to this compound be preſented a third ſubſtance that has no affinity at all with one of theſe two primary ſubſtances, but has a greater affinity with the other than thoſe two ſubſtances have with each other, there will enſue a decompoſition, and a new union; that is, the third ſubſtance will ſeparate the two compounding ſubſtances from each other, coaleſce with that which has an affinity with it, form therewith a new combination, and diſengage the other, which will then be left at liberty, and ſuch as it was before it had contracted any union.

Sixthly, It happens ſometimes, that when a third ſubſtance is preſented to a body, conſiſting of two ſubſtances, no decompoſition follows; but the two compounding ſubſtances, without quitting each other, unite with the ſubſtance preſented to them, and form a combination of three principles: and this happens when that third ſubſtance has an equal, or nearly equal, affinity with each of the compounding ſubſtances. The ſame thing may alſo happen, even when the third ſubſtance hath no affinity but with one of the compounding ſubſtances only. To produce ſuch an effect, it is ſufficient that one of the two compounding ſubſtances have, to the third body, a relation equal, or nearly equal, to that which it has to the other compounding ſubſtance with which it is already combined. Thence it follows, that two ſubſtances, which, when apart from all others, are incapable of contracting any union, may be rendered capable of incorporating together, in ſome meaſure, and becoming parts of the ſame compound, by combining them with a third ſubſtance with which each of them has an equal affinity.

Seventhly, A body, which of itſelf cannot decompoſe a compound conſiſting of two ſubſtances, becauſe they have a greater affinity with each other than it has with either of them, becomes nevertheleſs capable of ſeparating the two by uniting with one of them, when it is itſelf combined with another body, having a degree of affinity with that one ſufficient to compenſate its own deficiency: in that caſe there are two affinities; and thence enſues a double decompoſition and a double combination.

Mr. Geoffroy's Table of AFFINITIES *Explained.* See plate VII. *fig.* 1. where this table is exhibited, and the various characters, of which it conſiſts, are explained.

The late Mr. Geoffroy, being convinced of the advantages which all who cultivate chemiſtry would receive from having conſtantly before their eyes a ſtate of the beſt aſcertained relations between the chief agents in chemiſtry, was the firſt who undertook to reduce them into order, and unite them all in one point of view, by means of a table. We are of opinion, with that great man, that this table will be of conſiderable uſe to ſuch as are beginning to ſtudy chemiſtry, in helping them to form a juſt idea of the relations which different ſubſtances have with one another; and that the practical chemiſt will be thereby enabled to account for what paſſes in ſeveral of his operations, otherwiſe difficult to be underſtood, as well as to judge what may be expected to reſult from mixtures of different compounds. Theſe reaſons have induced us to inſert the table itſelf on the copper-plate above referred to, and to give a ſhort explanation of it here.

This table appears in the original form, as drawn up by Mr. Geoffroy himſelf, without any addition or alteration: for though we are perſuaded it might be improved, as many experiments have ſince been made, ſome of which have diſcovered new affinities, and others raiſed exceptions to ſome of thoſe laid down by that chemiſt: yet ſeveral reaſons diſſuade us from publiſhing a new table of affinities, containing all the emendations and innovations that might be made in the old one. And it will be ſufficient here to obſerve, that many of the affinities lately diſcovered are not yet ſufficiently verified; but, on the contrary, ſubject to be conteſted: in ſhort, they are perhaps liable to more conſiderable objections and exceptions than the other.

The upper line of Mr. Geoffroy's table comprehends ſeveral ſubſtances uſed in chemiſtry. Under each of thoſe ſubſtances are ranged, in diſtinct columns, ſeveral matters compared with them, in the order of their relation to that firſt ſubſtance; ſo that the body neareſt to it is that which hath the greateſt affinity with it, or that which none of the ſubſtances ſtanding below it can ſeparate therefrom; but which, on the contrary, ſeparates them all when they are combined with it, and expels them, in order to join itſelf therewith. The ſame is to be underſtood of that which occupies the ſecond place of affinity; that is, it has the ſame property with regard to all below it, yielding only to that which is above it: and ſo of all the reſt.

At the top of the firſt column ſtands the character which denotes an acid in general. Immediately under this ſtands the mark of a fixed alkali, being placed there as the ſubſtance which has the greateſt affinity with an acid. After the fixed alkali appears the volatile alkali, whoſe affinity with acids yields only to the fixed alkali. Next come the abſorbent earths; and, laſt of all, metallic ſubſtances. Hence it follows, that when a fixed alkali is united with an acid, it cannot be ſeparated therefrom by any other ſubſtance; that a volatile alkali, united with an acid, cannot be ſeparated from it by any thing but a fixed alkali; that an abſorbent earth, combined with an acid, may be ſeparated from it either by a fixed or a volatile alkali; and laſtly, that any metallic ſubſtance, combined with an acid, may be ſeparated from it by a fixed alkali, a volatile alkali, or an abſorbent earth.

There are many important remarks to be made on this column. Firſt, it is making the rule too general to ſay, that any acid whatever has a greater affinity with a fixed alkali than with any other ſubſtance: and, indeed, Mr. Geoffroy himſelf hath made an exception with reſpect to the vitriolic acid; for in the fourth column, at the head of which ſtands that acid, we find the ſign of the phlogiſton placed above that of the fixed alkali, as having a greater affinity than the fixed alkali with the vitriolic acid. This is founded on the famous experiment, wherein vitriolated tartar and Glauber's ſalt are decompounded by means of the phlogiſton, which ſeparates the fixed alkalis of theſe neutral ſalts, and uniting with the vitriolic acid contained in them, forms therewith a ſulphur.

Secondly, nitre deflagrates, and is decompoſed, by the contact of any inflammable matter whatever that is actually on fire; and the operation which produces phoſphorus is no other than a decompoſition of ſea-ſalt, whoſe acid quits its alkaline baſis to join with the phlogiſton: now theſe facts furniſh very ſtrong reaſons for believing that both theſe acids, as well as the vitriolic, have a ſtronger affinity with the phlogiſton than with a fixed alkali. Laſtly, as ſeveral experiments ſhew the vegetable acids to be only the mineral acids diſguiſed and mortified, there are ſufficient grounds for ſuſpecting that acids in general have a greater affinity with the phlogiſton than with fixed alkalis: ſo that, inſtead of making an exception with regard to the vitriolic acid, it would perhaps be better to lay down this greater affinity as common to all acids whatever, and to place the phlogiſton in the firſt column, immediately under the character which denotes an acid in general. This theory, however, ſhould not be implicitly adopted, till confirmed from other experiments.

Thirdly, in this column, the character of a volatile alkali is ſet above that of an abſorbent earth, as having a greater affinity with acids; and yet theſe abſorbent earths decompoſe the ammoniacal ſalts, drive away the volatile alkali from the acids, and aſſume its place. This is one of the firſt objections made againſt Mr. Geoffroy's table. His anſwer thereto is printed in the

Memoirs of the Academy of Sciences for 1718, where his table alſo may be ſeen. The reader may ſee our opinion of this matter under the article *Volatile* ALKALI.

Fourthly, in 1744, Mr. Geoffroy, brother to the author of the table, preſented a memoir to the Academy, containing an exception to the laſt affinity in the firſt column; namely, that which places abſorbent earths above metallic ſubſtances. He therein ſhews, that allum may be converted into copperas by boiling it in iron veſſels; that on this occaſion, the iron precipitates the earth of the allum, ſeparates it from its acid, and aſſumes its place; ſo that of courſe it muſt have a greater affinity than the abſorbent earth of allum with the vitriolic acid.

At the head of the ſecond column ſtands the character of the marine acid, which ſignifies that the affinities of this acid are the ſubject of the column. Immediately below it is placed the mark of tin. As this is a metalline ſubſtance, and as the firſt column places metalline ſubſtances in the loweſt degree of affinity with all acids, it is plain we muſt ſuppoſe fixed alkalis, volatile alkalis, and abſorbent earths to be placed here in order after the marine acid, and before tin. Tin, then, is of all metalline ſubſtances, that which has the greateſt affinity with the marine acid; and then follow regulus of antimony, copper, ſilver, mercury, gold comes laſt of all; and there are no leſs than two vacant places above it. By this means, it is in ſome ſort excluded from the rank of ſubſtances that have an affinity with the marine acid. The reaſon is, that this acid alone is not capable of diſſolving gold and combining therewith, neceſſarily requiring for that purpoſe, the aſſiſtance of the nitrous acid, or at leaſt of the phlogiſton.

The third column exhibits the affinities of the nitrous acid, the character whereof ſtands at its head. Immediately below it is the ſign of iron, as the metal which has the greateſt affinity with this acid; and then follow other metals, each according to the degree of its relation; namely, copper, lead, mercury, and ſilver. In this column, as in the preceding, we muſt ſuppoſe the ſubſtances, which in the firſt column ſtand above metallic ſubſtances, to be placed in their proper order before iron.

The fourth column is intended to repreſent the affinities of the vitriolic acid. Here Mr. Geoffroy has placed the phlogiſton as the ſubſtance which has the greateſt affinity with this acid, for the reaſon given in our explanation of the firſt column. Below it he has ranked fixed alkalis, volatile alkalis, and abſorbent earths, to ſhew that this is an exception to the firſt column. As to metalline ſubſtances, he has ſet down but three, being thoſe with which the vitriolic acid has the moſt perceptible affinity: theſe metals, placed in the order of their affinities, are iron, copper, and ſilver.

The fifth column ſhews the affinities of abſorbent earths. As theſe earths have no ſenſible affinity but with acids, this column contains only the characters of the acids ranked according to the degree of their ſtrength, or affinity with the earths; namely, the vitriolic, the nitrous and the marine acids. Underneath the laſt might be placed the acid of vinegar, or the vegetable acid.

The ſixth column expreſſes the affinities of fixed alkalis with acids, which are the ſame with thoſe of abſorbent earths. Here we find ſulphur placed below all the acids; becauſe liver of ſulphur, which is a combination of ſulphur with a fixed alkali, is actually decompounded by any acid: for any acid precipitates the ſulphur and unites with the alkali.

Immediately over the ſulphur, or in the ſame ſquare with it, might be placed a character, denoting the volatile ſulphureous ſpirit; becauſe, like ſulphur, it has leſs affinity than any other acid with fixed alkalis. Oils might alſo be ranked with ſulphur, becauſe they unite with fixed alkalis, and therewith form ſoaps, which are decompounded by any acid whatever.

The ſeventh column points out the affinities of volatile alkalis, which are likewiſe the ſame as thoſe of abſorbent earths; and the vegetable acid might be placed here alſo under the marine acid.

The eighth column ſpecifies the affinities of metallic ſubſtances with acids. The affinities of the acids, which with reſpect to fixed alkalis, volatile alkalis, and abſorbent earths, ſucceeded each other uniformly, do not happen in the ſame order here. The marine acid, inſtead of being placed below the vitriolic and nitrous acids, ſtands, on the contrary, at their head; becauſe, in fact, this acid ſeparates metalline ſubſtances from all the other acids with which they happen to be united, and forcing theſe acids to quit poſſeſſion, intrudes into their place. This is not however a general rule; for ſeveral metalline ſubſtances muſt be excepted, particularly iron and copper.

The ninth column declares the affinities of ſulphur, fixed alkalis, iron, copper, lead, ſilver, regulus of antimony, mercury, and gold, ſtand below it in the order of the affinities. With regard to gold, it muſt be obſerved, that it will not unite with pure ſulphur; it ſuffers itſelf to be diſſolved only by the liver of ſulphur, which is known to be a compoſition of ſulphur and fixed alkali.

At the head of the tenth column appears mercury, and beneath it ſeveral metalline ſubſtances, in the order of their affinities with it. Theſe metalline ſubſtances are gold, ſilver, lead, copper, zinc, and regulus of antimony.

It is proper to remark on this column, that regulus of antimony, which ſtands the loweſt, unites but very imperfectly with mercury; and that after a ſeeming union of theſe two metallic ſubſtances hath been obtained, by a tedious trituration with the addition of water, they do not continue long united, but ſpontaneouſly ſeparate from each other in a ſhort time. Iron and tin are here excluded; the former with great reaſon, becauſe hitherto it hath not been clearly proved, by any known experiment, that ever mercury was united with iron; but the ſame objection cannot be made to tin, which amalgamates very well with mercury, and might therefore be placed in this column nearly between lead and copper. We uſe the word nearly, becauſe the different degrees of affinity between metalline ſubſtances and mercury are not ſo exactly determined, as the other relations before conſidered; for they generally unite with it, without excluding one another. We can therefore ſcarce judge of the degree of affinity that belongs to each, but by the greater or leſs readineſs of each to amalgamate therewith.

The eleventh column ſhews, that lead has a greater affinity with ſilver than with copper.

The twelfth, that copper has a greater affinity with mercury than with calamine.

The thirteenth, that ſilver has a greater affinity with lead than with copper.

The fourteenth contains the affinities of iron. Regulus of antimony ſtands immediately underneath it, as being the metallic ſubſtance which has the greateſt affinity with it. Silver, copper, and lead, are placed together in the next ſquare below, becauſe the degrees of affinity which thoſe metals have with iron, are not exactly determined.

The ſame may be obſerved of the fifteenth column; regulus of antimony ſtands at its head; iron is immediately below it; and below the iron, the ſame three metals occupy one ſquare, as before.

Laſtly, the ſixteenth column indicates, that water has a greater affinity with ſpirit of wine than with ſalts. By this general expreſſion muſt not be underſtood any ſaline ſubſtance whatever; but only the neutral ſalts, which ſpirit of wine frees from the water that kept them in ſolution. Fixed alkalis, on the contrary, as well as the mineral acids, have a greater affinity than ſpirit of wine with water; ſo that the ſaline ſubſtances, being well dephlegmated and mixed with ſpirit of wine, imbibe the water it contains, and rectify it.

To theſe might be added another ſhort column, having ſpirit of wine at its head; immediately below it ſhould be the character of water; and below that, the mark of oil. This column would ſhew that ſpirit of wine has a greater affinity with water than with oils; becauſe any oily matter whatever, diſſolved in ſpirit of wine, may be actually ſeparated from it by the effuſion of water. This rule admits of only one imperfect exception, which is, when the oily ſubſtance partakes of the nature of

ſoap, by having contracted an union with ſome ſaline matter. But as this muſt be imputed wholly to that adventitious ſaline matter being ſuperadded to the oily ſubſtance, it is no juſt foundation for an exception; and the affinity in queſtion is therefore general.

AFFIRMATION, in a general ſenſe, implies a ſolemn atteſtation of the truth of ſome fact.

Affirmation, among logicians, ſignifies an act of the mind, aſſerting the truth or reality of ſomething; or a poſitive propoſition declaring certain properties or qualities to belong to the thing in queſtion.

Affirmation, in law, denotes an indulgence allowed to the people called Quakers, who, in caſes where an oath is required from others, may make a ſolemn affirmation that what they ſay is true; and if they make a falſe affirmation, they are ſubject to the penalties of perjury. But this relates only to oaths taken to the government, and on public occaſions; for Quakers are not permitted to give their teſtimony in any criminal caſe, &c.

AFFIRMATIVE, in a general ſenſe, denotes any thing that implies an affirmation.

Affirmative *Propoſition.* See the article Propoſition.

Affirmatine *Quantity.* See Quantity.

Affirmative *Sign,* in algebra, is marked thus +. See Character.

The affirmative ſign before and between two or more numbers, quantities, or literal expreſſions, implies their ſum, addition, or aggregate, ſtanding inſtead of the words *more, plus,* or added to, and commodiouſly aſſiſting the imagination; as $+5$, $+7$, or *plus* 5, *plus* 7, or *more* 5, *more* 7, or 5 *added to* 7, ſignifies the ſum of 5 and 7, viz. 12; ſo alſo $+a$, $+b$, or *plus* a, *plus* b, or *more* a, *more* b, or a *added to* b, is the ſum of a and b. So alſo the lines $+AB+CD+EF$, ſignifies the ſum or aggregate of the lines AB, CD, and EF; that is, theſe lines put together.

AFFIX, among grammarians, implies a particle added to the end of a word.

AFFORESTING, in our old law-books, ſignifies the turning lands into a foreſt.

AFFRAY, in law, formerly ſignified the crime of affrighting, or terrifying; but at preſent denotes a fight or ſkirmiſh between two or more perſons.

The word is derived from the French, *affrayer*, to affright.

AFFREIGHTMENT, a term uſed in ſome law-books, for the freight or hire of a ſhip.

AFFRONTEE, in heraldry, is an appellation given to animals facing one another.

AFRICA, in geography, is a vaſt peninſula, forming one of the four quarters, or diviſions of the world. It is joined to Aſia by the Iſthmus of Suez, whilſt the Red-ſea and Eaſtern-ocean bound it on the eaſt. On the north it is bounded by the Mediterranean; on the ſouth by the Southern ocean; and on the weſt by the Atlantic ocean. It is about 6072 miles in length from north to ſouth, and 4200 in breadth from eaſt to weſt. The principal commodities of this large diviſion of the earth, are gold duſt, ambergriſe, elephants teeth, guinea-pepper, red-wood, hides, wax, ſaunders, ſugar, civet, oil, cardamums, hemp, flax, dates, almonds, indigo, gum, oſtrich feathers, amber, ebony, canes, citrons, lemons, oranges, copper, cocoa-nuts, ſaffron, cryſtal, and many other particulars, beſides ſlaves, with whom the American plantations of all the European powers are ſupplied.

Africa is repreſented, in painting, by a black woman almoſt naked, with frizzled, wooly hair, an elephant's trunk for a creſt, a lion on one ſide, and a ſerpent on the other; decorated with other emblems relating to the produce of the country.

AFT, in the ſea-language, ſignifies the ſame with abaft. See Abaft.

AFTER-BIRTH, in midwifery, ſignifies the membranes which ſurround the infant in the womb, generally called the ſecundines. See the article Delivery.

After-math, in huſbandry, denotes the graſs which ſprings up after mowing; or the graſs cut after the corn.

After-pains, in midwifery, exceſſive pains felt in the groin, loins, &c. after the woman is delivered.

After-swarms, in the management of bees, are thoſe which leave the hive ſome time after the firſt have ſwarmed.

AGA, among the Turks, ſignifies a great lord or commander. They ſometimes uſe the word agaſſi, or agaſi, inſtead of aga. Thus they call the aga, or commandant-general of the cavalry, ſpahilar agaſſi.

AGALOCHUM, in natural hiſtory, the name by which the lignum-aloes, or xylo-aloes, was known among the ancient Greeks. See Lignum-aloes.

AGALMATA, in antiquity, a term originally uſed to ſignify any kind of ornaments in a temple; but afterwards for the ſtatues only, as being moſt conſpicuous.

AGANIPPIDES, an appellation given to the muſes from a fountain on mount Helicon called Aganippe.

AGAPE, in eccleſiaſtical hiſtory, the love-feaſt, or feaſt of charity, in uſe among the primitive Chriſtians, when a liberal contribution was made by the rich to feed the poor.

The word is Gerek, and ſignifies love.

St. Chryſoſtom gives the following account of this feaſt, which he derives from the apoſtolical practice. He ſays, the firſt Chriſtians had all things in common, as we read in the Acts of the Apoſtles; but when that equality of poſſeſſions ceaſed, as it did even in the Apoſtles time, the agape, or love-feaſt, was ſubſtituted in the room of it. Upon certain days, after partaking of the Lord's Supper, they met at a common feaſt; the rich bringing proviſions, and the poor, who had nothing, being invited.

It was always attended with receiving the Holy Sacrament; but there is ſome difference between the ancient and modern interpreters as to the circumſtance of time; viz. Whether this feaſt was held before, or after the communion. St. Chryſoſtom is of the latter opinion; the learned Dr. Cave of the former.

Theſe love-feaſts, during the firſt three centuries, were held in the church; but at length ſuch abuſes were committed at them, that the councils of Laodicea and Carthage prohibited the practice for the future.

AGAPETÆ, in eccleſiaſtical hiſtory, young maidens, who frequented the company of eccleſiaſtics from a motive of piety and charity. But this cuſtom afterwards degenerating into libertiniſm, the agapetæ became a term of reproach.

The word is Greek, and ſignifies well-beloved. It is derived from *αγαπαω*, to love.

AGARIC, in natural hiſtory, a ſpongy fungous ſubſtance, growing on the trunk of a tree, or, in the language of the ancients, an excreſcence or apoſtem from age or diſeaſe. See plate I. *fig.* 13.

The tree that produces the agaric is the common larch, from which turpentine is obtained. It grows wild in Dauphiny, Savoy, on the Alps, in Auſtria, Tartary, &c. and is the only coniferous tree that ſheds its leaves in the winter: when it grows old, the fungus comes forth in ſeveral places on its trunk, and if the tree is large, on the firſt branches.

The fungus is of various ſizes, ſometimes not exceeding the bigneſs of the fiſt, ſometimes as large as a man's head: it takes at leaſt a year to grow to its full ſize. There are two kinds of it, called by the ancients *mas* and *femina*. The male agaric is dark-coloured, hard, heavy, and woody: it is ſeldom taken from the larch, but chiefly from old oak-trees, and hence is called by ſome agaric of the oak: it is quite unfit for any medicinal uſe, and is only now and then employed by the dyers as an ingredient in the black dye. The female, or officinal agaric, is covered with a hard blackiſh rind like the other; but when the cortical part is pared off, the internal ſubſtance appears quite white: by age, it changes a little yellowiſh. It ſhould be very light, porous, eaſy to break, free from any hard pieces or compact veins. Taſted, it proves at firſt ſweetiſh, but preſently becomes very bitter and nauſeous.

As agaric is an excreſcence from a very reſinous tree, it is natural for it to be rich in reſin. We find in effect that it contains three-fourths of its weight in reſinous matter, and that the remaining fourth is a ſlimy, mucilaginous earthy ſubſtance, ſo tenacious as ſcarce to be by any means diſſolved or divided; continuing, however,

AFFIRMATIVE, in a general ſenſe, denotes any thing that implies an affirmation.

Affirmative *Propoſition*. See the article Proposition.

Affirmatine *Quantity*. See Quantity.

Affirmative *Sign*, in algebra, is marked thus +. See Character.

The affirmative ſign before and between two or more numbers, quantities, or literal expreſſions, implies their ſum, addition, or aggregate, ſtanding inſtead of the words *more*, *plus*, or added to, and commodiouſly aſſiſting the imagination; as $+ 5$, $+ 7$, or *plus* 5, *plus* 7, or *more* 5, *more* 7, or 5 *added to* 7, ſignifies the ſum of 5 and 7, viz. 12; ſo alſo $+ a$, $+ b$, or *plus a*, *plus b*, or *more a*, *more b*, or *a added to b*, is the ſum of *a* and *b*. So alſo the lines $+ AB + CD + EF$, ſignifies the ſum or aggregate of the lines AB, CD, and EF; that is, theſe lines put together.

AFFIX, among grammarians, implies a particle added to the end of a word.

AFFORESTING, in our old law-books, ſignifies the turning lands into a foreſt.

AFFRAY, in law, formerly ſignified the crime of affrighting, or terrifying; but at preſent denotes a fight or ſkirmiſh between two or more perſons.

The word is derived from the French, *affrayer*, to affright.

AFFREIGHTMENT, a term uſed in ſome law-books, for the freight or hire of a ſhip.

AFFRONTEE, in heraldry, is an appellation given to animals facing one another.

AFRICA, in geography, is a vaſt peninſula, forming one of the four quarters, or diviſions of the world. It is joined to Aſia by the Iſthmus of Suez, whilſt the Red-ſea and Eaſtern-ocean bound it on the eaſt. On the north it is bounded by the Mediterranean; on the ſouth by the Southern ocean; and on the weſt by the Atlantic ocean. It is about 6072 miles in length from north to ſouth, and 4200 in breadth from eaſt to weſt. The principal commodities of this large diviſion of the earth, are gold duſt, ambergriſe, elephants teeth, guinea-pepper, red-wood, hides, wax, ſaunders, ſugar, civet, oil, cardamums, hemp, flax, dates, almonds, indigo, gum, oſtrich feathers, amber, ebony, canes, citrons, lemons, oranges, copper, cocoa-nuts, ſaffron, cryſtal, and many other particulars, beſides ſlaves, with whom the American plantations of all the European powers are ſupplied.

Africa is repreſented, in painting, by a black woman almoſt naked, with frizzled, wooly hair, an elephant's trunk for a creſt, a lion on one ſide, and a ſerpent on the other; decorated with other emblems relating to the produce of the country.

AFT, in the ſea-language, ſignifies the ſame with abaft. See Abaft.

AFTER-BIRTH, in midwifery, ſignifies the membranes which ſurround the infant in the womb, generally called the ſecundines. See the article Delivery.

After-math, in huſbandry, denotes the graſs which ſprings up after mowing; or the graſs cut after the corn.

After-pains, in midwifery, exceſſive pains felt in the groin, loins, &c. after the woman is delivered.

After-swarms, in the management of bees, are thoſe which leave the hive ſome time after the firſt have ſwarmed.

AGA, among the Turks, ſignifies a great lord or commander. They ſometimes uſe the word agaſſi, or agaſi, inſtead of aga. Thus they call the aga, or commandant-general of the cavalry, ſpahilar agaſſi.

AGALOCHUM, in natural hiſtory, the name by which the lignum-aloes, or xylo-aloes, was known among the ancient Greeks. See Lignum-aloes.

AGALMATA, in antiquity, a term originally uſed to ſignify any kind of ornaments in a temple; but afterwards for the ſtatues only, as being moſt conſpicuous.

AGANIPPIDES, an appellation given to the muſes from a fountain on mount Helicon called Aganippe.

AGAPE, in eccleſiaſtical hiſtory, the love-feaſt, or feaſt of charity, in uſe among the primitive Chriſtians, when a liberal contribution was made by the rich to feed the poor.

The word is Gerek, and ſignifies love.

St. Chryſoſtom gives the following account of this feaſt, which he derives from the apoſtolical practice. He ſays, the firſt Chriſtians had all things in common, as we read in the Acts of the Apoſtles; but when that equality of poſſeſſions ceaſed, as it did even in the Apoſtles time, the agape, or love-feaſt, was ſubſtituted in the room of it. Upon certain days, after partaking of the Lord's Supper, they met at a common feaſt; the rich bringing proviſions, and the poor, who had nothing, being invited.

It was always attended with receiving the Holy Sacrament; but there is ſome difference between the ancient and modern interpreters as to the circumſtance of time; viz. Whether this feaſt was held before, or after the communion. St. Chryſoſtom is of the latter opinion; the learned Dr. Cave of the former.

Theſe love-feaſts, during the firſt three centuries, were held in the church; but at length ſuch abuſes were committed at them, that the councils of Laodicea and Carthage prohibited the practice for the future.

AGAPETÆ, in eccleſiaſtical hiſtory, young maidens, who frequented the company of eccleſiaſtics from a motive of piety and charity. But this cuſtom afterwards degenerating into libertiniſm, the agapetæ became a term of reproach.

The word is Greek, and ſignifies well-beloved. It is derived from αγαπαω, to love.

AGARIC, in natural hiſtory, a ſpongy fungous ſubſtance, growing on the trunk of a tree, or, in the language of the ancients, an excreſcence or apoſtem from age or diſeaſe. See plate I. *fig*. 13.

The tree that produces the agaric is the common larch, from which turpentine is obtained. It grows wild in Dauphiny, Savoy, on the Alps, in Auſtria, Tartary, &c. and is the only coniferous tree that ſheds its leaves in the winter: when it grows old, the fungus comes forth in ſeveral places on its trunk, and if the tree is large, on the firſt branches.

The fungus is of various ſizes, ſometimes not exceeding the bigneſs of the fiſt, ſometimes as large as a man's head: it takes at leaſt a year to grow to its full ſize. There are two kinds of it, called by the ancients *mas* and *femina*. The male agaric is dark-coloured, hard, heavy, and woody: it is ſeldom taken from the larch, but chiefly from old oak-trees, and hence is called by ſome agaric of the oak: it is quite unfit for any medicinal uſe, and is only now and then employed by the dyers as an ingredient in the black dye. The female, or officinal agaric, is covered with a hard blackiſh rind like the other; but when the cortical part is pared off, the internal ſubſtance appears quite white: by age, it changes a little yellowiſh. It ſhould be very light, porous, eaſy to break, free from any hard pieces or compact veins. Taſted, it proves at firſt ſweetiſh, but preſently becomes very bitter and nauſeous.

As agaric is an excreſcence from a very reſinous tree, it is natural for it to be rich in reſin. We find in effect that it contains three-fourths of its weight in reſinous matter, and that the remaining fourth is a ſlimy, mucilaginous earthy ſubſtance, ſo tenacious as ſcarce to be by any means diſſolved or divided; continuing, however,

ſoap, by having contracted an union with ſome ſaline matter. But as this muſt be imputed wholly to that adventitious ſaline matter being ſuperadded to the oily ſubſtance, it is no juſt foundation for an exception; and the affinity in queſtion is therefore general.

AFFIRMATION, in a general ſenſe, implies a ſolemn atteſtation of the truth of ſome fact.

AFFIRMATION, among logicians, ſignifies an act of the mind, aſſerting the truth or reality of ſomething; or a poſitive propoſition declaring certain properties or qualities to belong to the thing in queſtion.

AFFIRMATION, in law, denotes an indulgence allowed to the people called Quakers, who, in caſes where an oath is required from others, may make a ſolemn affirmation that what they ſay is true; and if they make a falſe affirmation, they are ſubject to the penalties of perjury. But this relates only to oaths taken to the government, and on public occaſions; for Quakers are not permitted to give their teſtimony in any criminal caſe, &c.

AFFIRMATIVE, in a general ſenſe, denotes any thing that implies an affirmation.

AFFIRMATIVE *Propoſition.* See the article PROPOSITION.

AFFIRMATINE *Quantity.* See QUANTITY.

AFFIRMATIVE *Sign,* in algebra, is marked thus +. See CHARACTER.

The affirmative ſign before and between two or more numbers, quantities, or literal expreſſions, implies their ſum, addition, or aggregate, ſtanding inſtead of the words *more, plus,* or added to, and commodiouſly aſſiſting the imagination; as + 5, + 7, or *plus* 5, *plus* 7, or *more* 5, *more* 7, or 5 *added to* 7, ſignifies the ſum of 5 and 7, viz. 12; ſo alſo + *a*, + *b*, or *plus a, plus b,* or *more a, more b,* or *a added to b*, is the ſum of *a* and *b*. So alſo the lines + A B + C D + E F, ſignifies the ſum or aggregate of the lines A B, C D, and E F; that is, theſe lines put together.

AFFIX, among grammarians, implies a particle added to the end of a word.

AFFORESTING, in our old law-books, ſignifies the turning lands into a foreſt.

AFFRAY, in law, formerly ſignified the crime of affrighting, or terrifying; but at preſent denotes a fight or ſkirmiſh between two or more perſons.

The word is derived from the French, *affrayer*, to affright.

AFFREIGHTMENT, a term uſed in ſome law-books, for the freight or hire of a ſhip.

AFFRONTEE, in heraldry, is an appellation given to animals facing one another.

AFRICA, in geography, is a vaſt peninſula, forming one of the four quarters, or diviſions of the world. ſoap, by having contracted an union with ſome ſaline matter. But as this muſt be imputed wholly to that adventitious ſaline matter being ſuperadded to the oily ſubſtance, it is no juſt foundation for an exception; and the affinity in queſtion is therefore general.

AFFIRMATION, in a general ſenſe, implies a ſolemn atteſtation of the truth of ſome fact.

Affirmation, among logicians, ſignifies an act of the mind, aſſerting the truth or reality of ſomething; or a poſitive propoſition declaring certain properties or qualities to belong to the thing in queſtion.

Affirmation, in law, denotes an indulgence allowed to the people called Quakers, who, in caſes where an oath is required from others, may make a ſolemn affirmation that what they ſay is true; and if they make a falſe affirmation, they are ſubject to the penalties of perjury. But this relates only to oaths taken to the government, and on public occaſions; for Quakers are not permitted to give their teſtimony in any criminal caſe, &c.

AFFIRMATIVE, in a general ſenſe, denotes any thing that implies an affirmation.

Affirmative *Propoſition*. See the article Propoſition.

Affirmatine *Quantity*. See Quantity.

Affirmative *Sign*, in algebra, is marked thus +. See Character.

The affirmative ſign before and between two or more numbers, quantities, or literal expreſſions, implies their ſum, addition, or aggregate, ſtanding inſtead of the words *more*, *plus*, or added to, and commodiouſly aſſiſting the imagination; as $+5$, $+7$, or *plus* 5, *plus* 7, or *more* 5, *more* 7, or 5 *added to* 7, ſignifies the ſum of 5 and 7, viz. 12; ſo alſo $+a$, $+b$, or *plus a*, *plus b*, or *more a*, *more b*, or *a added to b*, is the ſum of a and b. So alſo the lines $+AB+CD+EF$, ſignifies the ſum or aggregate of the lines AB, CD, and EF; that is, theſe lines put together.

AFFIX, among grammarians, implies a particle added to the end of a word.

AFFORESTING, in our old law-books, ſignifies the turning lands into a foreſt.

AFFRAY, in law, formerly ſignified the crime of affrighting, or terrifying; but at preſent denotes a fight or ſkirmiſh between two or more perſons.

The word is derived from the French, *affrayer*, to affright.

AFFREIGHTMENT, a term uſed in ſome law-books, for the freight or hire of a ſhip.

AFFRONTEE, in heraldry, is an appellation given to animals facing one another.

AFRICA, in geography, is a vaſt peninſula, forming one of the four quarters, or diviſions of the world. It is joined to Aſia by the Iſthmus of Suez, whilſt the Red-ſea and Eaſtern-ocean bound it on the eaſt. On the north it is bounded by the Mediterranean; on the ſouth by the Southern ocean; and on the weſt by the Atlantic ocean. It is about 6072 miles in length from north to ſouth, and 4200 in breadth from eaſt to weſt. The principal commodities of this large diviſion of the earth, are gold duſt, ambergriſe, elephants teeth, guinea-pepper, red-wood, hides, wax, ſaunders, ſugar, civet, oil, cardamums, hemp, flax, dates, almonds, indigo, gum, oſtrich feathers, amber, ebony, canes, citrons, lemons, oranges, copper, cocoa-nuts, ſaffron, cryſtal, and many other particulars, beſides ſlaves, with whom the American plantations of all the European powers are ſupplied.

Africa is repreſented, in painting, by a black woman almoſt naked, with frizzled, wooly hair, an elephant's trunk for a creſt, a lion on one ſide, and a ſerpent on the other; decorated with other emblems relating to the produce of the country.

AFT, in the ſea-language, ſignifies the ſame with abaft. See Abaft.

AFTER-BIRTH, in midwifery, ſignifies the membranes which ſurround the infant in the womb, generally called the ſecundines. See the article Delivery.

After-math, in huſbandry, denotes the graſs which ſprings up after mowing; or the graſs cut after the corn.

After-pains, in midwifery, exceſſive pains felt in the groin, loins, &c. after the woman is delivered.

After-ſwarms, in the management of bees, are thoſe which leave the hive ſome time after the firſt have ſwarmed.

AGA, among the Turks, ſignifies a great lord or commander. They ſometimes uſe the word agaſſi, or agaſi, inſtead of aga. Thus they call the aga, or commandant-general of the cavalry, ſpahilar agaſſi.

AGALOCHUM, in natural hiſtory, the name by which the lignum-aloes, or xylo-aloes, was known among the ancient Greeks. See Lignum-aloes.

AGALMATA, in antiquity, a term originally uſed to ſignify any kind of ornaments in a temple; but afterwards for the ſtatues only, as being moſt conſpicuous.

AGANIPPIDES, an appellation given to the muſes from a fountain on mount Helicon called Aganippe.

AGAPE, in eccleſiaſtical hiſtory, the love-feaſt, or feaſt of charity, in uſe among the primitive Chriſtians, when a liberal contribution was made by the rich to feed the poor.

The word is Gerek, and ſignifies love.

St. Chryſoſtom gives the following account of this feaſt, which he derives from the apoſtolical practice. He ſays, the firſt Chriſtians had all things in common, as we read in the Acts of the Apoſtles; but when that equality of poſſeſſions ceaſed, as it did even in the Apoſtles time, the agape, or love-feaſt, was ſubſtituted in the room of it. Upon certain days, after partaking of the Lord's Supper, they met at a common feaſt; the rich bringing proviſions, and the poor, who had nothing, being invited.

It was always attended with receiving the Holy Sacrament; but there is ſome difference between the ancient and modern interpreters as to the circumſtance of time; viz. Whether this feaſt was held before, or after the communion. St. Chryſoſtom is of the latter opinion; the learned Dr. Cave of the former.

Theſe love-feaſts, during the firſt three centuries, were held in the church; but at length ſuch abuſes were committed at them, that the councils of Laodicea and Carthage prohibited the practice for the future.

AGAPETÆ, in eccleſiaſtical hiſtory, young maidens, who frequented the company of eccleſiaſtics from a motive of piety and charity. But this cuſtom afterwards degenerating into libertiniſm, the agapetæ became a term of reproach.

The word is Greek, and ſignifies well-beloved. It is derived from *αγαπαω*, to love.

AGARIC, in natural hiſtory, a ſpongy fungous ſubſtance, growing on the trunk of a tree, or, in the language of the ancients, an excreſcence or apoſtem from age or diſeaſe. See plate I. *fig.* 13.

The tree that produces the agaric is the common larch, from which turpentine is obtained. It grows wild in Dauphiny, Savoy, on the Alps, in Auſtria, Tartary, &c. and is the only coniferous tree that ſheds its leaves in the winter: when it grows old, the fungus comes forth in ſeveral places on its trunk, and if the tree is large, on the firſt branches.

The fungus is of various ſizes, ſometimes not exceeding the bigneſs of the fiſt, ſometimes as large as a man's head: it takes at leaſt a year to grow to its full ſize. There are two kinds of it, called by the ancients *mas* and *femina*. The male agaric is dark-coloured, hard, heavy, and woody: it is ſeldom taken from the larch, but chiefly from old oak-trees, and hence is called by ſome agaric of the oak: it is quite unfit for any medicinal uſe, and is only now and then employed by the dyers as an ingredient in the black dye. The female, or officinal agaric, is covered with a hard blackiſh rind like the other; but when the cortical part is pared off, the internal ſubſtance appears quite white: by age, it changes a little yellowiſh. It ſhould be very light, porous, eaſy to break, free from any hard pieces or compact veins. Taſted, it proves at firſt ſweetiſh, but preſently becomes very bitter and nauſeous.

As agaric is an excreſcence from a very reſinous tree, it is natural for it to be rich in reſin. The

treated with water, a tough gluey paſte. The purgative quality of agaric reſides in the reſin: to the glutinous matter we may attribute the dangerous conſequences, which, when given in ſubſtance, however corrected, it is apt to produce. No wonder that ſuch a coheſive indiſſoluble ſubſtance ſhould adhere pertinaciouſly to the ſtomach and inteſtines, and occaſion gripes and other inconveniencies.

From eight ounces of very good agaric, I obtained, by rectified ſpirit, ſix ounces of reſinous extract; from the reſiduum only two drams and two ſcruples of watry extract; the indiſſoluble tenacious matter weighed two ounces one dram and a half: ſo that there was, upon the whole, an increaſe of near half an ounce above the original weight of the agaric, from a part of the menſtrua retained. On applying water, at firſt I got but bare three drams of extract; on treating the remainder with ſpirit, I gained near as much reſin as when the ſpirit was uſed at firſt, namely, five ounces and ſeven drams; the indiſſoluble matter weighed, when dry, two ounces and two drams.

In reducing agaric to powder, whether by the raſp or the peſtle, great care muſt be taken to avoid the fine duſt that flies off, which is not only apt to occaſion violent ſneezing and inflammations of the eyes, but is likewiſe very prejudicial to the breaſt. Agaric cannot of itſelf be pulverized in a mortar, on account of its glutinous ſubſtance: the beſt way of obtaining a powder from it is, firſt to raſp, and then make it into a paſte with mucilage of gum tragacanth; when this is thoroughly dry, great part of it may be beat into a fine powder, and by treating the remainder in the ſame manner, the whole will at length be got through a ſieve. It might be ſuppoſed, that as it is the mucilaginous part of agaric itſelf that prevents its pulverization, the addition of freſh mucilage would do more harm than good; but the mucilage of gum tragacanth is of a quite different nature from that of agaric, being ſoluble, harmleſs, when dry brittle, and rendering the agaric alſo pulverable. In ſome diſpenſatories, a reſinous extract is directed to be prepared from this fungus, by rectified ſpirit. *Neumann's Chemiſtry.*

The agaric of the oak has been lately recommended as an external ſtyptic; and has been even ſaid to prevent hæmorrhages after amputation, as effectually as the painful operation of the needle. To render the agaric fit for this application, the internal ſoft part of the fungus muſt be divided into pieces of different ſizes, and beaten with a hammer till it may be eaſily torn with the fingers. In this condition it is to be applied to the orifices of the veſſels, and covered with the uſual dreſſings. In a ſhort time the extremities of the veſſels are ſaid to be found contracted into a conical ſhape, and the orifices ſtopt with plugs of coagulated blood, ſufficient to reſiſt the force of the circulation. Caſes have been publiſhed, in which this application ſeemed to anſwer the above character; and others, in which it proved ineffectual: ſo that the agaric has loſt great part of its repute.

Nor does it ſeem to be poſſeſſed of any conſiderable degree of ſtyptic power. Perhaps it only acts as a ſoft pliable ſubſtance, adhering to the orifices of the veſſels, till they have contracted ſpontaneouſly. This will appear the more probable, when we remember, that other fungi have formerly been uſed in the ſame intention; and that there are late accounts in the Philoſophical Tranſactions of two different ſpecies which have been uſed with ſucceſs; namely, the lycoperdon, or duſty muſhroom, and that found on caſks, and the walls of wine-vaults, called fungos vinoſus.

Mineral AGARIC, in natural hiſtory, a light marley earth, ſo called from its reſembling, both in colour and its ſpongy texture, the vegetable agaric. Some have recommended it in fluxes, hæmorrhages, and to dry up old ulcers; but it is very rarely, if ever, uſed at preſent.

AGARICOIDES, in botany, a ſort of ſmall white fungus, with yellowiſh lamellæ, found frequently in the woods on the bark of old trees.

The word is compounded of the Greek, αγαρικον, agaric, and ειδος, reſemblance.

AGATE, in natural hiſtory, a precious ſtone reſembling the onyx, with regard to colour: but has no zones like thoſe wherewith the onyx is decorated: inſtead of thoſe, the agate has lines or ſpots of various colours, diſpoſed in ſuch a manner as to repreſent the pictures of different objects; as woods, rivers, fruits, flowers, herbs, and clouds, though not very diſtinctly.

Boet tells us, that he had himſelf an agate which, tho' no bigger than the finger-nail of a man, was marked with a perfect circle, within which was the figure of a biſhop, with a mitre on his head.

The agate differs from the jaſper in hardneſs and ſmoothneſs; for though the jaſper has the ſame colours, it is ſofter, and conſiſts of rougher particles.

The white-veined agate, with delineations of trees and moſſes, is moſt commonly known by the name of the Mocha ſtone. It is of a very firm compact, and fine texture, though found in the ſhape of a flinty pebble ſtone. The ſizes are various, being ſometimes only one, and ſometimes eight inches in diameter. The veins of this ſtone are very beautifully diſpoſed in different figures; but there are generally many concentric irregular circles, deſcribed from centers placed in various places. They are commonly a little whiter than the ground, though ſometimes ſo faint as ſcarcely to be ſeen. Thoſe of this kind are of the higheſt value, and contain the figures of trees, moſſes, ſea-plants, and the like. Some have ſuppoſed that theſe ſtones are only petrifications; and that real moſſes and ſea-plants were included therein: but this is evidently a miſtake; for the real objects which they repreſent were never met with in ſo diminutive a ſize as their images repreſented in theſe ſtones. No one ſurely can ſeriouſly imagine that there ever was a perfect tree no more than half an inch high. Theſe figures are generally black, or of a duſky colour, and appear with great advantage from the whiteneſs of the ſtone. This kind of agate, when it is perfect, is only found in the Eaſt Indies; but there are ſome of an inferior ſort to be met with in Germany. They are called Mocha ſtones, becauſe they have been brought from the Eaſt Indies to Mocha in Arabia, and thence tranſported into Europe. There are, however, ſome naturaliſts who will not allow them to be found in the Eaſt Indies. If this be true, they may be found near the place to which they owe their name; or perhaps be brought to Mocha from other parts of Arabia, or even Africa.

The dull milky agate is not ſo valuable as the former, though of a very firm texture. They are found in the ſhape of common flint ſtones, and are from one inch to ten in diameter. It is of the colour of milk, or rather like that of cream; and, when broken, has a ſmooth gloſſy ſurface. It is more opaque than the former, and yet will bear a very fine poliſh. This ſpecies is common on the ſhores of the rivers in the Eaſt Indies; and there are ſome of leſs value met with in Germany and Bohemia. This ſpecies of agate was in far more eſteem formerly than at preſent, becauſe it is now very common.

The lead-coloured agate, with black and white veins, is, by Boet, called the phaſſachates; and is of a very fine, firm, compact texture; though found, like the former, in the ſhape of common flint ſtones, and of as rugged a ſurface. The ground is of a pale bluiſh grey, or rather of a dove-colour; and often without variation, though it has ſometimes black and ſometimes white veins, which are generally near the centre of the ſtone. This ſpecies of agate greatly reſembles an onyx, but is certainly a diſtinct ſtone. It is very hard, and will bear a fine poliſh. It is found in the Eaſt Indies, as well as in Germany; where they form theſe ſtones into cups and ſnuff-boxes.

The fleſh-coloured agate is not ſo valuable as any of the former, though its texture is pretty firm and compact; and its diameter from one to ten inches. The fleſh-colour is very faint, and almoſt whitiſh; but never entirely wanting. Some of theſe ſtones have no veins at all, and others abound in veins, ſpots, or clouds. The ſpots are generally very ſmall, about the ſize of a pin's head, notched at the edges; though ſometimes much leſs. When broken in pieces, it is very ſmooth and gloſſy, though not always of the ſame tranſparency. It is found in Germany, Bohemia, and Italy; and is worked into various ſorts of veſſels: it is alſo often made uſe of inſtead of gun-flints.

The blood-coloured agate is, by Boet, called the hæmachates, and excels moſt of this claſs in beauty. It is always of a deep blood-red colour, ſometimes throughout, but more frequently variegated with a pale blue and brown. The blue always ſurrounds the red, and inclines to the colour of whey; but it is in no other part of the ſtone. The brown is of the colour of horn, and generally appears in irregular veins, ſometimes in ſuch plenty as to make the ground to the ſtone, and the red with its blue edges only the variegation. This ſpecies is not very common, though found in the Eaſt Indies, America, and ſome parts of Germany. It is chiefly uſed for the tops of ſnuff-boxes.

The clouded and ſpotted fleſh-coloured agate is, by Boet, called the ſandachates, and is of a very fine cloſe texture, though ſubject to flaws and cracks when the pieces are large; for which reaſon the leſſer ſtones are moſt eſteemed. It differs from the former ſpecies in having a ſmoother ſurface; and is generally of a roundiſh or oblong ſhape, a little flatted. It has no variegations except a few exceeding ſmall ſpots, of a beautiful red, variouſly diſpoſed in different parts of the ſtone, and in different groupes. In ſome places it is more tranſparent than others; and is found in the Eaſt and Weſt Indies, as alſo in Bohemia and Sileſia, though not ſo good. It is, however, very little eſteemed at preſent.

The red agate, variegated with yellow, is of the colour of red lead, has a fine pure equal texture, with a ſmooth regular ſurface, and is commonly found in the ſhape of a pebble ſtone. It is from one inch to four or five in diameter, and its ground of a paler red, decorated with one of a deeper colour, diſpoſed in concentric veins from different centers; but this does not appear without cloſe examination. Beſides theſe, it has irregular bright yellow ſpots, which are never interſected by the veins, but placed either within or without theſe circles; and always extremely ſhort, being never above a ſixth part of an inch in length. This ſtone is very hard, and will bear a very fine poliſh. It is found in the Eaſt Indies, though not very common.

The yellow agate, named, by Boet, the cerachates, or the wax-coloured agate, has been found from one to ſeven inches in diameter, of various ſhapes and ſizes, but all of a very firm compact texture. Theſe ſtones are ſometimes of the ſame colour throughout; ſometimes mixed with irregular veins; and ſometimes of a pale and almoſt white ground, veined and ſpotted with a ſtrong yellow, exactly reſembling that of fine yellow bees-wax. They are all very hard and capable of a fine poliſh; but differ greatly in degrees of tranſparency; for ſome are as tranſparent as any of the ſpecies of agate, and others almoſt entirely opaque. Theſe ſtones are found in the Eaſt Indies and America, as alſo in Germany, though not very good.

The pale yellow agate, variegated with white, black, and green, is called, by Boet, the leonina, from its likeneſs to a lion's ſkin, and by the Italians brocatella. It is more variegated than the reſt of the ſtones of this kind, and has a fine compact cloſe texture, though in very irregular ſhapes, with a rugged ſurface. It ſometimes ſeems to conſiſt of an irregular maſs, made up of the above-mentioned colours; ſometimes diſtinctly clouded, and ſometimes decorated with black and green veins in the form of concentric circles round a centre. The ground is always of a pale yellow, but very differently diſpoſed; ſometimes more, ſometimes leſs. In ſome alſo, one or more of theſe colours are wanting, while others contain them all. The green reſembles that of the jaſper, and the black inclines a little to the brown. It breaks with ſome difficulty into pieces, with fine ſmooth ſurfaces, and is brought from the Eaſt Indies; but, being very ſcarce, is not commonly known.

The blackiſh veined brown agate has, when found, a pretty ſmooth ſurface, though of an irregular ſhape, and is from two to ſeven inches in diameter. The brown is pretty deep, and finely clouded, ſpotted, and veined with a colour almoſt black, while the veins are generally paler and browner than the other variegations. The veins are diſpoſed in irregular concentric circles, and the innermoſt generally broadeſt. There have ſometimes been vegetable ſubſtances found in the middle of this ſtone, ſuch as the ſlender roots of moſs, or thoſe of crow ſilk. It is capable of a very high and beautiful poliſh; and is commonly cut into ſeals, buttons, heads of canes, knife-handles, and the tops of ſnuff-boxes. It is frequently adorned with fictitious colours, which ſink ſo deep into the ſubſtance, that they appear like the natural veins of the ſtone, and render it of great value.

The greeniſh brown variegated agate ſeems to be of a middle nature, between agate and jaſper. It is a beautiful ſpecies, and found in roundiſh maſſes, with a ſmooth even ſurface, from two to ſix inches in diameter. Its texture is very firm, and the ſtone ſometimes of the ſame colour throughout, being only diſtinguiſhable from the true jaſper by its hardneſs. But it has moſt frequently a browniſh green ground, variegated with irregular concentric circles, of a red or a finer green; it is alſo found irregularly clouded and ſpotted with the ſame or other colours, as white, fleſh-colour, and yellow. It is never entirely tranſparent in thoſe that are cleareſt; and is found in different parts of the world, but not equally good; for the European are the worſt, they being more coarſe, ſoft, and opaque, than thoſe of the Eaſt or Weſt Indies. *Brookes's Natural Hiſt.*

AGATE is alſo the name of an inſtrument uſed by gold wire-drawers; ſo called from the agate in the middle of it, which forms its principal part.

AGATY, in botany, the name of a genus of trees growing in Malabar, about twenty-four feet in height, and the trunk ſix feet in circumference. The agaty bears papilionaceous and ſcentleſs flowers, which are ſucceeded by pods three feet in length, and half an inch in breadth, containing ſeeds reſembling our kidney beans, which the natives eat with their food.

AGE, in a general ſenſe, denotes a certain portion, or part of duration, applied to ſome particular object. Thus we ſay the age of the world, or the years that have elapſed ſince the creation.

AGES *of the World.* The greater part of hiſtorians and chronologers have divided the age of the world into ſix principal epochas; but are not agreed between themſelves with regard to the number of years contained in each interval. Thoſe who place the creation ſix thouſand years before the birth of Chriſt, make the interval between the creation and the deluge to conſiſt of 2262 years; from the deluge to the call of Abraham, 1198, from the call of Abraham to the inſtitution of the Paſſover, 645; from the inſtitution of the Paſſover to the beginning of the reign of Saul, 774; from Saul to the publiſhing of the decree of Cyrus, for the return of the Jews, 583; and from the decree of Cyrus to the birth of Chriſt, 538.

Thoſe who make the age of the world at the birth of Chriſt only four thouſand years, follow the chronology of the Hebrew text, and compute from the creation to the deluge, 1656 years; from the deluge to the call of Abraham, 426; from the call of Abraham to the exodus, or going out of Egypt, 430; from the exodus to the foundation of the temple, 480; from the foundation of the temple to Cyrus, 476; and from Cyrus to the birth of Chriſt, 532.

Others compute from the creation to the taking of Troy, 2830 years; from the taking of Troy to the foundation of Rome, 420; from the foundation of Rome to the deſtruction of Carthage by Scipio, 602; from the deſtruction of Carthage to the birth of Chriſt, 200; from the birth of Chriſt to Conſtantine, 312; and thence to the re-eſtabliſhment of the weſtern empire, 808. So that the interval, according to theſe chronologers, between the creation and the birth of Chriſt, is 4052 years.

To theſe computations of the ages of the world, we ſhall add another, from the learned Mr. Jackſon's Chronological Antiquities, who has carefully inveſtigated the different epochas, and ſhewn the reaſons on which his computations are founded. From the creation to the deluge, 2262 years; from the deluge to the birth of Abraham, 1072; from the birth of Abraham to the exodus, 505; from the exodus to the foundation of the temple, 579; from the foundation to the deſtruction of the temple by Nebuchadnezzar, 428; from the deſtruction of the temple to the decree of Cyrus, 51; and from the decree of Cyrus to the birth of Chriſt, 535. So that the interval between the creation and the birth of our bleſſed Saviour, conſiſts of 5432 years.

Some divide the duration of the world into three periods, which they call the age of the law of nature; the age of the Jewiſh law; and the age of grace. The firſt comprehends the time between Adam and Moſes; the ſecond the time between that lawgiver and Chriſt; and the third the years elapſed ſince the birth of our bleſſed Saviour.

The ancient hiſtorians divided the time elapſed ſince the beginning of the world into three periods, which they called ages. The firſt reaches from the creation to the deluge which happened in Greece during the reign of Ogyges: this they ſtiled the obſcure or uncertain age; becauſe the hiſtory of mankind is altogether uncertain during that period. The ſecond they named the fabulous, or heroic age; becauſe it is the period in which the fabulous accounts of their gods and heroes are ſaid to have been performed: it began at the Ogygian deluge, and extended to the firſt Olympiad; where, what they called, the hiſtorical age commenced.

Age, among hiſtorians, is alſo often uſed to ſignify a century.

Poetical Ages *of the World.* The poets have divided the interval ſince the formation of man into four ages, which they have diſtinguiſhed by the epithets of *golden*, *ſilver*, *brazen*, and *iron*. During the *golden age*, Saturn reigned in Heaven, and juſtice and innocence in this lower world. The earth then yielded her productions without culture, and ſtreams of milk and honey flowed in every part. The *ſilver age* commenced when men began to deviate from the paths of virtue; and, in conſequence of this deviation, their lives were rendered leſs happy. The *brazen age* began when the virtue and happineſs of men were ſtill more diminiſhed; and this gave place to the *iron age*, which commenced when men had deviated ſtill farther from the paths of virtue and happineſs. Such is the ſyſtem which Heſiod, in his treatiſe intitled *Works and Days*, has given more at large; and where the poet has repreſented, in a very inſtructive allegory, the melancholy conſequences which always flow from injuſtice.

Age alſo denotes a certain degree or period of human life, which is generally divided into four ſtages; namely, infancy, youth, manhood, and old age. The firſt extends to the fourteenth year; the ſecond to the twenty-fifth year; the third to the fiftieth year; and the fourth to the end of life.

Age, in law, ſignifies certain periods of human life, when perſons of either ſex are enabled to do certain acts, which, for want of years and diſcretion, they are incapable of before. Thus a youth of twelve years of age may take the oath of allegiance; at fourteen, he may chooſe his guardian and claim his lands held in ſoccage. Twenty-one is called full age, a man or woman being then capable of acting for themſelves, and of managing their own affairs.

Age *of a Tree*, ſignifies the time elapſed between its being planted and cut down.

The age of a tree may be known by the ligneous circles viſible in its trunk, divided horizontally by a ſaw: for both the trunk and branches of a tree acquire annually an augmentation of a ligneous circle, or a new exterior texture of fibres.

Age *of a Horſe*, implies the time elapſed ſince the animal was foaled.

This is eaſily known by his mouth till he is eight years old, when the marks wear out. A horſe, like many other creatures of the brute-creation, has his teeth divided into three ranks; his fore-teeth, which are flat and ſmooth; his tuſhes; and his back teeth, called alſo his jaw-teeth, or grinders, becauſe with theſe he grinds his provender. They are twenty-four in number, twelve above, and twelve below; ſtrong and double, with ſharp edges, till the creature grows old, when they are worn much ſmoother.

The firſt that grow are his foal-teeth, which begin to appear a few months after he is foaled. They are twelve in number, ſix above and ſix below; and are eaſily diſtinguiſhed from the teeth that come up afterwards, by their ſmallneſs and whiteneſs, not unlike the fore-teeth of a man.

When a colt is about two years and a half old, he caſts the four middlemoſt of his foal-teeth, viz. two above and two below; though ſome do not caſt their foal-teeth till near three years old. The new teeth are eaſily diſtinguiſhed from the foal-teeth, being much ſtronger, and almoſt twice their ſize, and are called the nippers or gatherers, being thoſe by which the creature nips off the graſs when he is feeding abroad in the fields, or, when in the houſe, gathers his hay from the rack. When a horſe has got theſe four teeth complete, he is reckoned four years old.

When he is about three and a half, or in the ſpring before he is four years old, he caſts four more of his foal-teeth, viz. two above and two below, one on each ſide of the nippers, or middle teeth. When, therefore, you look in a horſe's mouth, and ſee the four middle teeth full grown, and none of the fore-teeth remaining, except the corner teeth, you may conclude he is four years old about April or May: ſome, indeed, are later colts; but this makes but little difference in the mouth.

The tuſhes appear about the ſame time with the laſt-mentioned teeth, ſometimes ſooner than theſe, and ſometimes not till a horſe is full four years old. They are curved like the tuſhes of other beaſts; but in a young horſe they have a ſharp edge all round the top, and on both ſides, the inſide being ſomewhat grooved and flattiſh, inclined to a hollowneſs.

When horſes tuſhes do not appear till ſome time after the foal-teeth are caſt, and new ones are come in their room, it is generally owing to the foal-teeth having been pulled out before their time by the breeders or other dealers in horſes, in order to make a colt of three years old appear like one of four, that he may be the more ſaleable; for when any of the foal-teeth are pulled out, the others ſoon come in their place; but the tuſhes, having none to precede them, cannot make their appearance before their proper time, viz. when a horſe is nearly four years old. One of the ſureſt marks therefore to know a four-year old horſe, is by his tuſhes, which are then but very ſmall, and ſharp on the top and edges.

When a horſe comes five, or rather the ſpring before he is five, the corner teeth begin to appear, and are at firſt but juſt equal with the gums, being filled with fleſh in the middle. The tuſhes are alſo by this time grown to a more diſtinct ſize, though not very large; they alſo continue rough and ſharp on the top and edges. But the corner teeth are now moſt to be remarked: they differ from the middle teeth in being more fleſhy on the inſide, and the gums generally look rawiſh on their firſt ſhooting out; whereas the others do not look diſcoloured.

The middle teeth arrive at their full growth in leſs than three weeks; but the corner teeth grow leiſurely, and are ſeldom much above the gums till the horſe is full five: they differ alſo from the other fore-teeth, in reſembling, in ſome meaſure, a ſhell; and thence are called the ſhell-teeth; becauſe they environ the fleſh in the middle half-way round, and, as they grow, the fleſh within diſappears, leaving a diſtinct hollowneſs and openneſs on the inſide. When a horſe is full five, theſe teeth are generally about the thickneſs of a crown piece above the gums. From five to five and a half, they grow about a quarter of an inch high; and when a horſe is full ſix, they will be near half an inch above the gums.

The corner teeth in the upper jaw fall out before thoſe of the under; ſo that the upper corner teeth are ſeen before thoſe below: on the contrary, the tuſhes in the under jaw come out before thoſe of the upper.

When a horſe is full ſix years old, the hollowneſs on the inſide begins viſibly to fill up, and that which was at firſt fleſhy, grows into a browniſh ſpot, not unlike the eye of a dried garden-bean, and continues ſo till he is ſeven, with only this difference, that the tooth is more filled up and even, and the mark or ſpot becomes faint, and of a lighter colour. At eight the mark in moſt horſes is quite worn out, though ſome retain the veſtiges of it for a long time; and thoſe who have not had a good deal of experience may ſometimes be deceived, and take a horſe of nine or ten years old for one of eight. It is only at this time, when a horſe is paſt mark, that we can eaſily err in knowing the age of a horſe; for whatever practices are uſed to make a young horſe look older than he really is, by pulling out the foal-teeth before their time, may be diſcovered by feeling along the edges where the tuſhes grow, as they may be felt in the gums before the corner teeth appear; whereas, if the corner teeth become viſible ſome months before the tuſhes riſe in the gums, there is reaſon to ſuſpect that the foal-teeth have been pulled out at three years old.

It will be unneceſſary to take particular notice of the tricks uſed by dealers, in order to make a falſe mark in a horſe's mouth, by hollowing the tooth with a graver, and burning a mark with a ſmall hot iron; becauſe thoſe who are acquainted with the true marks, will eaſily diſcover the cheat by the ſize and colour of the teeth, by the roundneſs and bluntneſs of the tuſhes, by the colour of the falſe mark, which is generally blacker and more impreſſed than the true mark, and by many other viſible tokens which denote the advanced age of a horſe. *Gibſon's Treatiſe on Horſes.*

AGE *of the Moon*, in aſtronomy, is the number of days elapſed ſince the laſt new moon: to find which, add together the epact, the day of the current month, and the number for the month; the ſum, if it exceeds not 29, is the age of the moon; but if it be more, deduct 29 from it in months which have but 30 days, and 30 in thoſe which have 31 days, the remainder will be the moon's age. See EPACT.

The number to be added for each month is as follows: for January 0, February 2, March 1, April 2, May 3, June 4, July 5, Auguſt 6, September 8, October 8, November 10, and December 10.

At the end of 19 years, the moon's age returns upon the ſame day of the month, but falls ſhort of the preciſe time of the day.

AGEMOGLANS, AGIAMOGLANS, or AZAMOGLANS, in the Turkiſh polity, are children purchaſed from the Tartars, or raiſed every third year, by way of tribute, from the Chriſtians tolerated in the Turkiſh empire.

The word, in the original, ſignifies a *barbarian's child*, or, according to the notion of the Muſſulmans, one whoſe parents are not Turks; and is compounded of two Arabic words, *agem*, barbarian, and *oglan*, a child.

Theſe, after being circumciſed, and inſtructed in the religion and language of their tyrannical maſters, are learnt the exerciſes of war, till they are of a proper age for carrying arms: and from this corps the janiſſaries are recruited. With regard to thoſe who are thought unfit for the army, they are employed in the loweſt offices of the ſeraglio. Their appointments alſo are very ſmall, not exceeding ſeven aſpres and a half per day, which amount to about three-pence halfpenny of our money.

AGENDA, among philoſophers and divines, ſignifies the duties which a man is obliged to perform.

The word is Latin, and derived from *ago*, to perform.

AGENDA, among merchants, implies a memorandum book, in which all the buſineſs to be tranſacted, both at home and abroad, is ſet down.

AGENORIA, in mythology, the goddeſs of courage and induſtry. She was oppoſed to Vacuna, the goddeſs of indolence.

AGENT, in a general ſenſe, implies any thing that acts and produces an effect.

The word is Latin, *agens*, and derived from *ago*, to perform.

AGENT, in mechanics and philoſophy, ſignifies a body, or any power in general, which produces or tends to produce any effect by its actual motion, or tendency to motion. See POWER and ACTION.

AGENT, among merchants, denotes a perſon intruſted with the management of an affair, or who tranſacts the buſineſs of another.

Moral AGENT, a rational creature, capable of regulating his actions by a certain rule.

AGENT *and Patient*, in law, is ſaid of a perſon who is at once the doer of a thing, and the party to whom it is done. Thus if a man who is indebted to another, makes his creditor his executor, and dies, the executor may retain ſo much of the goods of the deceaſed as will ſatisfy his debt; by which means he becomes agent and patient; that is, the perſon who both pays and receives the debt.

AGEOMETRIA, ſomething defective with regard to geometry, or not founded on the principles of that ſcience.

The word is Greek, and compounded of *α*, priv. and *γεωμετρια*, geometry.

AGERATUM, Maudlin, in botany, a plant with a woody root, variouſly contorted, and as thick as one's little finger, and full of ſmall fibres; from this ariſe ſtalks a cubit high, which are ſlender, round, branched, and of a reddiſh colour, though ſome are of a pale green. This plant has a vaſt number of narrow leaves, an inch or two in length, and deeply ſerrated on the edges; on the top of the branches are bunches compoſed of radiated yellow flowers, whoſe diſk conſiſts of many floretts, but the borders are compoſed of half floretts; the embryoes are lodged in the flower-cap, which is ſcaly, and each becomes one ſlender ſeed of a pale yellow colour. It has been ſuppoſed to open obſtructions of the viſcera, being taken in infuſion or decoction; but is now little uſed for that purpoſe. *Brookes's Natural Hiſt.*

AGGLUTINANTS, in pharmacy, a general name for all medicines of a glutinous or viſcous nature; which, by adhering to the ſolids, contribute greatly to repair their loſs.

The word is Latin, *agglutinantia*, and compounded of *ad*, to, and *gluten*, glue.

AGGLUTINANTS, among ſurgeons, are topical remedies of a glutinous texture, as the turpentines, ſarcocolla, iſinglaſs, &c.

AGGLUTINATION, among phyſicians, implies the action of reuniting the parts of a body, ſeparated by a wound, cut, &c.

It is alſo applied to the action of ſuch internal medicines as are of an agglutinating quality, and which, by giving a glutinous conſiſtence to the animal fluids, render them more proper for nouriſhing the body.

AGGRAVATION, the action of heightening a fault, or rendering it more criminal.

AGGREGATE, in a general ſenſe, implies the ſum of ſeveral things added together, or the collection of them into one total.

The word is compounded of the Latin, *ad*, to, and *grex*, a flock, or company.

Thus natural bodies are the aggregate or aſſemblages of corpuſcles, united together by the principle of attraction; and the aggregate of the ſeveral quantities is the ſum of theſe quantities. See the article SUM.

AGGREGATION, in natural philoſophy, ſignifies a ſpecies of union whereby ſeveral things, not connected by nature, are collected together, ſo as to form one whole.

AGGRESSOR, in law, ſignifies the perſon who began the quarrel, or gave the firſt aſſault.

It is of the utmoſt importance to know which of the two parties is really the aggreſſor, and accordingly this matter is ſtrictly enquired into by the court.

AGIADES, in the Turkiſh armies, are a ſort of pioneers, employed in fortifying camps, and the like offices.

AGIDIES, in antiquity, was an epithet which the pagans gave to the prieſts of Cybele.

The word ſignifies jugglers, or thoſe who play tricks of legerdemain.

AGIO, in commerce, is a term chiefly uſed in Holland, and at Venice, to ſignify the difference between the value of bank ſtock and the current coin.

The agio, in Holland, is generally three or four per cent. and at Rome it is from fifteen to twenty-five per cent. but at Venice the agio is fixed at twenty per cent.

AGIO is alſo uſed to ſignify the profit ariſing from diſcounting notes, bills of exchange, &c.

AGIOGRAPHA, a name given to thoſe books which are read in the church as proper for edification only. They form what is generally called the apocrypha.

The word is Greek, and compounded of *αγιος*, ſacred, and *γραφω*, to write.

AGISTMENT, or AGISTATION, in law, ſignifies the taking in other people's cattle to graze at ſo much per week.

The term is peculiarly uſed for the taking cattle to feed in the king's foreſts, as well as for the profits ariſing from that practice.

Agistment is alſo uſed in a metaphorical ſenſe to ſignify any tax, burden, or charge. Thus the tax levied for repairing the Banks of Romney Marſh, was called agiſtamentum.

AGISTOR, or Agistator, an officer belonging to foreſts, who has the care of the cattle taken in to be grazed, and who levies the monies due on that account. They are generally called queſt-takers, or giſt-takers, and are created by letters patent. Each royal foreſt has four agiſtors.

AGITATION, the act of ſhaking a body, or toſſing it backwards and forwards.

The word is Latin, *agitatio*, and derived from *agito*, to ſhake.

Philoſophers apply this term to a ſpecies of earthquake called tremor and arietatio; and phyſicians to the ſhaking or motion of the inteſtinal parts of a natural body.

AGITATORS, in the Engliſh hiſtory, were certain officers ſet up by the army in 1647, to take care of its intereſts. Cromwell joined the agitators in order to promote his own intereſts; and accordingly cauſed them to be aboliſhed as ſoon as his own power was ſufficiently eſtabliſhed.

AGLEETS, Aglets, or Agleeds, among botaniſts, the ſame with what is more generally called apices. See the article Apices.

AGLIBOLUS, in mythology, an ancient deity of the Syrians, worſhipped at Palmyra. He was repreſented as a young man dreſſed in a tunick, girded round his waiſt, and reaching to his knees. The figure of the moon was placed on his buſkins, and he held a javelin in his right hand, and a ſmall baton, reſembling a roll, in his left.

The Palmyreans worſhipped the ſun under the name of *aglibolus*, which ſeems to be formed from the Arabic *ag*, *al*, *bal*, which ſignifies conſider, and *bolus*, or *belenus*, another name for Apollo, or the ſun.

AGNOITÆ, or Agnoites, a ſect of heretics that appeared about the year 370. They were the followers of Theophronius, the Cappadocian, and called in queſtion the omniſcience of the Supreme Being; alledging that he knew things paſt only by memory, and things future only by a precarious uncertain preſcience.

There was another ſect of heretics called by the ſame name, who maintained that Chriſt, with reſpect to his human nature, was ignorant of many things, and particularly of the Day of Judgment.

AGNOMEN, among the ancient Romans, was a kind of fourth, or honorary name, given to a perſon on account of ſome extraordinary action, virtue, or other accompliſhment.

AGNUS *Caſtus*, the chaſte-tree, in botany, is a ſmall tree, or rather ſhrub, with tough branches, digitated narrow leaves, and monopetalous purpliſh flowers, ſtanding in ſpikes on the tops of the branches, followed by oblong whitiſh ſeeds. It is a native of the warmer climates, and cultivated in ſome of our gardens.

The ſeeds of this plant were formerly conſidered as antiphrodiſiacs; perhaps on no other foundation than the ceremony obſerved by the Grecian matrons of old, of ſtrewing the leaves in the temples, at the celebration of the chaſte feſtivals of Ceres. Experience does not diſcover in them any ſuch virtue, and ſome have even aſcribed to them an oppoſite tendency.

But of whatever kind their virtues are, they do not, from their ſenſible qualities, appear to be very conſiderable. The ſeeds, as met with in the ſhops, have very little taſte, and ſcarcely any ſmell, though deſcribed by authors as very hot and biting: extracts made from them, by water or ſpirit, are weakly bitteriſh, and ſomewhat pungent. They ſeem to abound chiefly with a groſs inſipid oil, of the expreſſible kind, which is, in part, taken up by rectified ſpirit, and ſeparates and falls to the bottom during the inſpiſſation of the tincture. The oily matter is of a deep ſaffron colour, the inſpiſſated extract ſomewhat paler. *Lewis's Hiſtory of the Materia Medica.*

Agnus Dei, in the Roman church, ſignifies a cake of wax, ſtamped with the figure of a lamb ſupporting a croſs.

Theſe are conſecrated with great ſolemnity, and afterwards diſtributed to the people.

The words are pure Latin, and ſignify *lamb of God*; a name given it from the figure impreſſed upon it.

Agnus *Scythicus*, the Scythian lamb, in natural hiſtory, the name of a fictitious plant, reſembling a lamb, ſuppoſed to grow in Tartary. But Kæmpfer, who viſited this country, and made the moſt diligent enquiry after the Scythian lamb, was at laſt convinced that it has no exiſtence: and that the curioſities ſhewn under this name, are nothing more than factitious ſubſtances, partly formed out of the capillary roots of certain plants.

AGOGE, among the ancient muſicians, ſignified a ſpecies of modulation, when the notes proceeded by contiguous degrees.

The word is Greek, αγωγη, and derived from αγω, to lead.

AGON, among the ancients, implied any diſpute or conteſt, whether it had regard to bodily exerciſes, or the accompliſhments of the mind: and therefore poets, muſicians, painters, &c. had their agones, as well as the athletæ.

The word αγων is a radix, in the Greek language, and ſignifies a conteſt.

Games of this kind were celebrated at moſt of the heathen feſtivals, with great ſolemnity, either annually, or at certain periods of years. Among the latter were celebrated at Athens, the *agon gymnicus*, the *agon nemeus*, inſtituted by the Argives in the fifty-third Olympiad, and the *agon Olympius*, inſtituted, by Hercules, 430 years before the firſt Olympiad.

The Romans alſo, in imitation of the Greeks, inſtituted conteſts of this kind. The emperor Aurelian eſtabliſhed one under the name of *agon ſolis*; the conteſt of the ſun; Diocleſian another, which he called *agon capitolinis*, which was celebrated every fourth year, after the manner of the Olympic games.

Agon alſo ſignified one of the miniſters employed in the heathen ſacrifices, and whoſe buſineſs it was to ſtrike the victim.

AGONALIA, among the ancient Romans, were ſolemn feaſts celebrated in honour of the god Janus, or, according to ſome writers, in honour of the god Agonius, whom the Romans always invoked before they undertook any enterprize of importance.

AGONISTICI, a name given, by Donatus, to ſuch of his diſciples as he ſent to fairs, markets, and other publick places, to preach and propagate his doctrine.

AGONITHETA, in ancient hiſtory, the preſident or magiſtrate who preſided at the ſacred games, and adjudged the prizes to the victors.

The word is Greek, and compounded of αγων, conteſt, and τιθημι, to place, or diſpoſe.

AGONY, among phyſicians, denotes extreme pain, or the utmoſt efforts of nature ſtruggling with a diſeaſe.

AGONYCLITÆ, or Agonyclites, in eccleſiaſtical hiſtory, a ſect of Chriſtians in the ſeventh century, who always prayed in a ſtanding poſture, thinking it unlawful to kneel.

The word is Greek, and compounded of α, priv. γονυ, the knee, and κλινω, to bend or incline.

AGORÆUS, in antiquity, an epithet applied to ſuch deities as had ſtatues in the market places.

The word is Greek, and derived from αγορα, a market.

AGRANOMUS, a magiſtrate eſtabliſhed by the ancient Greeks at Athens, to regulate the weights and meaſures, the prices of proviſions, &c.

The word is Greek, αγορανομος, and compounded of αγορα, a market, and νεμω, to diſtribute or direct.

AGRARIAN, in a general ſenſe, implies ſomething belonging to, or connected with lands.

The word is derived from the Latin, *ager*, a field.

Agrarian *Laws*, among the Romans, were thoſe relating to the diviſion and diſtribution of lands; and of theſe there were a great number; but that called the

Agrarian law, by way of eminence, was publiſhed by Spurius Caſſius, about the year of Rome 268, for dividing the conquered lands equally among all the citizens, and limiting the number of acres each citizen might enjoy.

AGREEMENT, in law, ſignifies the conſent of two or more perſons to any thing done, or to be done.

AGRICULTURE, in a general ſenſe, implies the art of rendering the earth fertile by tillage and culture.

The word is Latin, *agricultura*, and compounded of *ager*, a field, and *colo* to till.

If we look into the earlieſt accounts of the eaſtern nations, their magnificent and populous cities, and their numerous armies, we ſhall have ſufficient reaſon to think, that agriculture was then arrived at a conſiderable perfection; ſince it could ſupply the inhabitants in general with all the neceſſaries of life, and the great with the moſt delicate luxuries. This will appear ſtill more evidently, if we reflect on the judicious conduct of the Egyptians, in the diſpoſition of their country, with reſpect to the inundations of the Nile, and the great advantages they had been taught to reap from it, as deſcribed by Herodotus. The poſſeſſions of the children of Iſrael muſt have been cultivated with the utmoſt ſkill and aſſiduity, or they could never have afforded ſuſtenance to the prodigious numbers of people, who, as indiſputable authority informs us, inhabited that ſmall ſpot. But time has robbed us of their knowledge in this moſt uſeful of arts.

In the moſt enlightened ages, books of Huſbandry were compoſed by men whoſe exalted ſtation ſufficiently indicates the high value then ſet upon the art they taught. Xenophon, equally diſtinguiſhed in philoſophy and in arms, ſhews, by his commendations of Cyrus, the eſtimation in which agriculture was held by both thoſe great men. Hieron, king of Syracuſe, did not think it beneath his dignity to write upon this eſſential art, for the benefit of his ſubjects. The chiefs of the two greateſt republics in the world, Cato, conſul of Rome, and Mago, ſufes of Carthage, employed part of their time in teaching the art of huſbandry. Theſe pieces are, in the opinion of the ancients, the beſt calculated for explaining rural affairs. Amidſt the Aſiatic luxury, and that of the Roman empire, valuable treatiſes of huſbandry appeared, written by Attalus, king of Pergamus; by Archelaus, king of Cappadocia; by Valerius Aſiaticus, who was judged worthy of the empire, after the death of Caligula; and by the emperor Albinus.

Some few fragments of the Greeks are the firſt rudiments of huſbandry upon record; and the elder Cato is the moſt ancient Latin author whoſe writings upon this intereſting ſubject have reached our hands. His inſtructions are very judicious, but too conciſe. Varro added elegance of language to an improved Treatiſe of Agriculture; and, ſoon after him, Virgil publiſhed his juſtly admired Georgics; by far the moſt laboured and highly finiſhed of all his works: theſe, indeed, he had moſt at heart; and upon theſe he choſe to reſt his future reputation. Columella afterwards collected, with great judgment, whatever was valuable in the writings of his predeceſſors, and enriched them with his own obſervations on the ſubject. His work is one of the choiceſt remains of antiquity, and has ſcarcely been equalled by any author ſince his time.

The irruptions of the barbarous nations of the north, unacquainted with the ſweets of ſociety, and the bleſſings of civil liberty, ſoon aboliſhed improved agriculture. Arms were their only object. Their meaneſt ſlaves were intruſted with their trifling huſbandry; and trifling it muſt have been during that unſettled ſtate of nations. Theſe innumerable and enterpriſing barbarians, who over-ran all Europe, were originally ſhepherds or hunters, like the preſent Tartars and the ſavages of America. They contented themſelves with poſſeſſing, without labour or trouble, the vaſt deſarts which their arms had made, and cultivated, very ſuperficially, only a ſmall ſpot near their habitations. The abject condition of thoſe whom they employed for this purpoſe, unfortunately and unjuſtly cauſed the occupation itſelf, then to be looked upon as mean and ignoble. But when governments began to be founded upon more fixed and rational plans, agriculture, with the other arts, reared its head, and throve in proportion as property became ſecure. A commonwealth gave the firſt riſe to the ſalutary change; for Venice may boaſt, that her Camillo Tarello was the firſt good author on this important ſubject, after the revival of uſeful knowledge.

The improvements made in England, in the reign of queen Elizabeth, ſhew, that the proteſtants, who were obliged to take ſhelter in the then free ſtates, and particularly in Switzerland, had, with their love of liberty, learned an improved agriculture. In the next age, Hartlib is not leſs famed for his knowledge in farming, than for his friendſhip with Milton. The return of the men of genius, who had fled their country during Cromwell's uſurpation, and the protection granted them after the reſtoration, added greatly to the progreſs of agriculture. At this period, from which England may date her grandeur, wealth, and power, writers of great character undertook the truly patriotic art. Such were Platt, Worlidge, Evelyn, &c. whoſe works did honour to the age, and proved highly beneficial to their country. The ſame laudable ſpirit appeared in an elegant ſyſtem, publiſhed about this time by the ingenious and learned counſellor Conrad Herreſbach, in Germany; where a ſpecial attention to agriculture had begun to be the great object of ſeveral ſtates, when a total ſtop was unhappily put to every thing of this kind, by the late war.

In France, two eminent phyſicians thought this ſubject worthy of their pens, and gave their country the *Maiſons Ruſtiques*, a work which, afterwards perfected by a third phyſician, has undergone twenty-two editions. Nor does that country now by any means loſe ſight of this important ſubject. Real philoſophers there make it their ſtudy, and purſue a ſeries of well-made experiments with ſuch indefatigable care and accuracy, as cannot fail of producing very great advantages; whilſt their monarch wiſely protects and patronizes their undertakings. In the ſame manner the emperor of China, throughout his wide dominions, rewards the huſbandman, who makes the beſt and greateſt improvements in his land, with the dignity of a mandarin of the eighth claſs. The names of ſeveral illuſtrious improvers in France, deſervedly diſtinguiſhed for their patriotic application to this ſtudy, will appear in many articles of this work. A ſociety in Brittany, in particular, have begun upon a moſt judicious plan, which promiſes ſuch ſucceſs as muſt prove extremely beneficial to their country.

In Switzerland, a ſociety eſtabliſhed at Berne has already favoured the world with ſuch ſpecimens of the great judgement of its illuſtrious members, as leave no room to doubt but that their diſtinguiſhed care and aſſiduity will be a laſting ſource of advantages to all mankind.

In Sweden, a genius has ariſen, who will ever deſerve the higheſt commendation in the hiſtory of Agriculture; though this is but a ſecondary part in his character. Linnæus has rouſed a ſpirit of enquiry into, and love of natural knowledge, which will undoubtedly be attended with conſpicuous emoluments to his native land.

In Denmark, a king, who, like our moſt auguſt ſovereign, makes the happineſs of his people the chief object of his care, is ſo attentive to agriculture, that thoſe gentlemen who travel at his expence, in order to learn, and introduce into his kingdom, every uſeful art, are directed to be particularly attentive to the art of huſbandry.

The general ſpirit of improvement in agriculture, ſo remarkably exerted in the different nations of Europe, calls upon us not to loſe that ſuperiority which the happineſs of our conſtitution and climate have given us.

The ſociety of improvers in the knowledge of agriculture in Scotland, will ever deſerve ſincere thanks for many proofs of that truly laudable ſpirit which conſults the general good of mankind: its worthy members ſet the noble example, and were firſt followed by the Dublin ſociety; next by another ſociety at Edinburgh; and now by one in London, in the more extenſive manner of adding premiums to the inſtruction only which the former gave.

The ſociety in Dublin have diſtinguiſhed themſelves ſo remarkably by their ſound and unbiaſſed judgment and aſſiduity, in promoting the real intereſt of their country, that the parliament of that kingdom are now become their patrons, and have, with a truly public ſpirit, ordered large ſums for carrying into execution their uſeful deſigns. Their obſervations, replete with excellent inſtructions, want only to be continued and increaſed.

The London ſociety for the encouragement of arts, manufactures, and commerce, is formed upon a plan ſo univerſally beneficent, and directed by gentlemen of ſuch high rank, and great abilities, as, when we conſider that they actually take every opportunity, which prudence and intelligence can ſuggeſt, to promote the laſting welfare of their fellow-citizens, ſcarcely leaves room for any farther wiſh, unleſs it be, that they would impart to the whole world ſome portion of their treaſures of uſeful knowledge. See Society *for the Encouragement of Arts, &c.*

That the real ſtrength of every country depends upon its population, is a well known truth; and a little acquaintance with the principles of ſound policy will ſhew, that the only ſolid baſis of a numerous population is agriculture. Without this, the ſubſiſtence of a nation is precarious. Uncertainty of ſubſiſtence hinders people from marrying, and even induces them to quit their native ſoil. Huſbandmen, whoſe children are their riches, are, of all perſons, the fitteſt and moſt inclined to propagate their ſpecies. Trade, though a great, is but a ſecondary, ſource of wealth, and will, if carried too far, deſtroy the parent which gave it birth, by diminiſhing agriculture, depopulating the country, and annihilating, by degrees, that eſſentially neceſſary claſs of men who cultivate the earth. Indolence and avidity will tempt them to quit a laborious occupation, for one that is attended with leſs toil and more lucre; though it be at the ſame time very precarious. The eaſe with which the artificers of luxury live, ſeduces the indigent peaſant, draws him to towns and cities, and the country is deſerted. But if agriculture be properly countenanced, encouraged, and put in ſo flouriſhing a ſtate as to afford a comfortable ſubſiſtence to the very great numbers that may be employed in it, the huſbandman will not forſake the ſolid occupation of his forefathers, to which he has been trained up; commerce will not exceed the bounds within which it ought to keep; luxury, that bane of mankind, will be effectually checked; and a martial ſpirit will animate every free-born youth:—for the courage of the lower claſs of unemployed people is but a kind of machinal inſtinct, allied at moſt with a certain love for their country, blended with the love of their own poſſeſſions. It is the robuſt labourer, hardened by fatigue, and by being expoſed to all ſorts of weather, who has the greateſt inward feeling of his own ſtrength: it is the huſbandman who is moſt firmly attached to his country, by the portion of land which maintains him. The artiſt, who ſettles wherever he finds employment, cannot, ſtrictly ſpeaking, be ſaid to have any country; though an uſeful member of the community, his retired ſedentary life weakens his body, and depreſſes the ſpring of that ſpirit of liberty, which elevates the ſoul as much as the ſervile courſes of luxury debaſe it:—of that ſpirit which ſo nobly diſtinguiſhed our illuſtrious forefathers, and which we have ſo lately, with pleaſure, ſeen revived in our preſent countrymen. Such was the ſpirit of the real Romans, of theſe conquerors of the world, whoſe only profeſſions were arms and agriculture, and who made equal improvements in both: nor, indeed, can any two in the whole circle of human employments be more fitly joined: for the ſturdy labouring youth, bred up to ſobriety and rural toil, makes the hardieſt ſoldier; and he who knows the fatigues and dangers of war, chearfully returns to the culture of his farm. Theſe were the men moſt prized by thoſe maſters of the univerſe: and, at this very day, the Arabians, who live under tents in the country, and remove occaſionally from place to place, deſpiſe the reſt of their nation who live in towns, look upon them as daſtardly and effeminate; and, after repeated defeats, now keep them in ſubjection.

Thoſe who imagine that a country life is repugnant to politeneſs, are ſurely much miſtaken. True politeneſs, the moſt cordial affection, the ſincereſt friendſhip, and unfeigned courteſy, without the grimace of ſtrained compliments, have often been found among the labouring rural race, inhabitants of thatched cottages. The appellations of rude and ruſtic were never given to really uſeful occupations, till luxury had debauched mankind, and a frivolous pertneſs uſurped the place of ſenſe and manners. Till then, men naturally eſteemed an art, of which every day's experience ſhewed them the abſolute neceſſity, as well as the great advantages. If the generality of country gentlemen are reproached with ruſticity of manners, it is their paſſion for ſporting, as they call it, and not their application to agriculture, which gives them that behaviour. There would be no room for this imputation, if they were oftener in the field with their workmen, than upon the turf, or in the thickets with their horſes and dogs.

But whilſt we are diſplaying a ſmall part only of the praiſe juſtly due to agriculture, let it not be imagined that, in our opinion, every man ſhould be a farmer. This is ſo far from being neceſſary, that it would inevitably bring us back to barbariſm. It is ſufficient that thoſe who are deſtined to it, be inſtructed and protected; and it will always be right in the legiſlature to conſider and examine the due degree of eſtimation in which this art ſhould be held, the juſt hopes that may reaſonably be entertained of its further progreſs, and the means by which it may beſt be carried to the greateſt perfection.

By proper application to this eſſential art, the philoſopher, from whom we muſt expect the greateſt improvements, will have a pleaſing opportunity of gratifying his deſire, by enlarging his knowledge of nature: the individual, who puts in practice the diſcoveries of the philoſopher, will find the ſureſt way of increaſing his fortune; and the ſovereign, who directs and favours the labours of all, will eſtabliſh his power, independent of all others, upon a foundation which cannot be ſhaken.

Agriculture may be ſubdivided into three different parts, comprehending the different ſoils required to be tilled:

1. Arable lands of all kinds, whether the ſoil be ſandy, clayey, loamy, &c. See Sandy, Clay, Loam, &c.
2. Lands employed in paſturage, whether meadow, marſhy, or boggy. See Meadow, Boggy, &c.
3. Wood-lands, or thoſe laid out in nurſeries, plantations, foreſts, woods, &c. See Wood-Lands, Forests, &c.

The reader will alſo find under the name of each tree and vegetable, as oak, beech, &c. wheat, barley, &c. the beſt methods of cultivating it to advantage. See alſo the different operations of huſbandry; as Plowing, Sowing, &c.

AGRIFOLIUM, the ſame with aquifolium. See Aquifolium.

AGRIMONIA, Agrimony, in botany, the name of a hairy plant, with winged leaves, compoſed of oblong indented ſegments, with ſmaller portions between, ſet on middle ribs which ſtand alternately on the ſtalk: on the top grows a like ſpike of pentapetalous yellow flowers, followed by little burs, containing, each, one or two ſeeds. It is perennial, and grows wild in hedges, and about the ſides of fields.

The leaves of agrimony have a ſlightly bitteriſh roughiſh taſte, accompanied with an agreeable, though very weak, aromatic flavour. The flowers are, in ſmell, ſtronger and more agreeable than the leaves, and in taſte ſomewhat weaker. They readily give out their virtues both to water and to rectified ſpirit: the leaves impart to the former a greeniſh yellow; to the latter a deep green colour: the flowers yield their own deep yellow tincture to both menſtrua. In diſtillation with water, there ariſes a very ſmall portion of a yellowiſh eſſential oil, which ſmells ſtrongly and agreeably of the herb.

Agrimony is one of the milder corroborants; and in this intention is ſometimes employed, eſpecially among the common people, againſt habitual diarrhæas, and cachectic, and other indiſpoſitions from a lax ſtate of the ſolids: infuſions of the leaves, which are not ungrateful, may be drank as tea. It is ſometimes joined with other ingredients in diet drinks for purifying the blood; and in pectoral apozems. *Lewis's Hiſtory of the Materia Medica.*

AGRIMOIDES, in botany, is the name of a genus of plants with roſaceous flowers, which, together with their cups, are received into another funnel-ſhaped cup, fimbriated at the edges. The proper cup of the flower becomes at length a pointed oval fruit, generally containing only one ſeed. It flowers in April, and grows in ſome of the mountainous parts of Italy. It agrees in its medicinal virtues with the agrimonia deſcribed in the preceding article.

AGRIMONY. See AGRIMONIA.

AGRIPPA, a name given by the ancients as well as modern phyſicians, to children born with their feet foremoſt. See DELIVERY.

AGROSTEMA, in botany, a diſtinct genus of decandrious plants, according to Linnæus; but comprehended by Tournefort in that of Lychnis. See LYCHNIS.

AGROSTIS, in botany, a diſtinct genus of plants, called in Engliſh quick-graſs, or couch graſs. See the article COUCH-GRASS.

AGROSTOGRAPHY, among naturaliſts, implies the hiſtory, or deſcription of graſſes.

The word is formed from the Greek, *αγρωστις*, graſs, and *γραφω*, to deſcribe.

Scheuchzer has publiſhed a treatiſe under the title of Agroſtographia, containing an accurate deſcription of ſeveral hundred ſpecies of graſs.

AGRYPNIA, among phyſicians, implies an inaptitude to ſleep, a troubleſome ſympton of feveriſh and other diſorders.

The word is Greek, *αγρυπνια*, and compounded of *α*, priv. and *υπνος*, ſleep.

AGRYPNIA, in the Greek church, implies the vigil of any of the greater feſtivals.

AGUAGUIN, in botany, the name of a ſhrub, whoſe leaves reſemble thoſe of our lilac; they grow alternately, and ſtand on foot ſtalks half an inch long. It is a native of Africa, where it is greatly eſteemed for its balſamic and vulnerary qualities.

AGUARA PONDA, in botany, the name of a ſpecies of violet, which grows to near a foot and a half in height, and bears a great reſemblance to the viola martia. See VIOLET.

AGUE, a general name for all periodical fevers, which, according to the different times of the returns of the feveriſh paroxyſm, are denominated tertian, quartian, and quotidian.

Tertian AGUE, is that which attacks the perſon every other day.

There is no fever which diſcovers the nature and genius of the febrile motion in general, and which at the ſame time infeſts the veſſels and nervous parts, ſo much as the tertian. It ſpares neither age, temperament, nor ſex.

When this ſpecies of intermitting fever is of the regular kind, it is attended with the following ſymptoms: at firſt, the head aches, the limbs ſeem weary, there is a pain in the loins about the firſt vertebra of the back, and which aſcends towards the epigaſtrium, with a painful ſenſe of a tenſion in the hypochondria, and a coſtiveneſs of the body. This is ſucceeded by a coldneſs of the external parts, eſpecially of the noſe and ears, a ſtretching, yawning, ſhivering, and ſhaking, ſometimes ſo much as to make the bed tremble under the patient; the pulſe is ſmall, contracted, and weak; ſometimes the patient is troubled with thirſt; then follows a nauſea, with a fruitleſs reaching to vomit; but ſometimes a pituitous, bilious, or green matter is brought up, commonly joined with a troubleſome cough, and an expectoration of phlegm, derived from the acid, clammy crudities of the ſtomach; to theſe ſucceeds an anxious, burning, and dry heat, which pervades the whole body; the face, which was collapſed and pale, the contracted, rigid ſkin, and the almoſt empty veſſels of the hands and feet, begin to riſe, grow red and turgid; the pulſe becomes more great, full and quick, reſtleſſneſs increaſes, the breathing is more difficult, and the patient, with his eyes almoſt cloſed, begins to talk a little wildly.

In ſome time the ſymptoms begin to abate, the heat becomes mild, the ſkin relaxes and becomes moiſt; the urine is of a flame colour, but without ſediment; the pulſe is more moderate, and then a ſweat breaking out, terminates the paroxyſm.

The duration of the fit is uncertain; ſometimes it ends in ten or eleven hours, and ſometimes not in twenty-four. On the intercalary day, the body is ſtill feeble and coldiſh, with a diſpoſition to ſhiver; the pulſe is ſlow and weak; the urine is turbid and depoſits a ſediment, or there is a nubecula, which ſhews a diſpoſition thereto.

The baſtard or ſpurious Tertian AGUE is attended with milder ſymptoms, the heat is not ſo burning, the vomiting is not ſo frequent, and the urine is not ſo high-coloured; but then it is more lingering, and on the intermediate day there is a laſſitude and want of appetite. This attacks men of an inactive diſpoſition, and women whoſe bodies are of a looſe texture, in the autumnal ſeaſon.

The fit of the irregular tertian obſerves no particular time, for it ſometimes comes on in the morning, ſometimes in the afternoon, in the evening, or at midnight. The paroxyſm is ſometimes longer, ſometimes ſhorter; the urine lets fall no ſediment within the time of remiſſion or intermiſſion; the ſweating is either too ſparing or too profuſe. When the fit is off ſeveral remarkable ſymptoms often appear, as a looſeneſs, a bleeding at the noſe, ſickneſs at the ſtomach, a violent heart-burn, or pains in the belly. Theſe ſort of agues are generally epidemic, and moſt commonly appear in the ſummer and autumn.

Sometimes a tertian ague is double, which may be diſtinguiſhed from a quotidian, by the time of the fits, which is not the ſame every day, but every other day.

Continual Tertian AGUE is that which begins with ſhivering and ſhaking, an anxiety, vomiting, loſs of ſtrength, and then a violent heat. The fits do not intermit, but only remit. The pulſe continues frequent with heat and debility, and all the ſymptoms return with freſh vigour every other day; but at length admit a perfect intermiſſion.

An endemic Tertian AGUE is proper to certain places, of a low ſituation, and full of marſhes, which produce a great number of gnats and other inſects, ſuch as ſome parts of Kent, and the Hundreds of Eſſex. In ſuch places the natives themſelves have ſlight attacks of it every year, and ſtrangers ſeldom or never eſcape without a preſervative, which is only the bark infuſed in brandy, with a little ſnake-root, two ounces of which are to be taken night and morning.

A Quartan AGUE is that which has two fits in four days, or two days quite free from a fit.

It generally begins about four or five in the afternoon, though ſometimes ſooner and ſometimes later, with a great laſſitude, ſtretching, a blunt pain in the head, back, loins, and legs; the feet and hands are cold, the whole body is pale, the face and nails livid, and the whole body affected with a ſhivering and ſhaking. The tongue and the lips tremble, the breathing is difficult, with reſtleſſneſs and toſſing; the pulſe is contracted and hard, and ſometimes unequal; and there is an anxiety about the præcordia. Theſe ſymptoms continue about two or three hours; in ſome the body is coſtive, in others there is a ſtimulus to ſtool and to make water: in ſome there is a nauſea or vomiting, with ſtools. Some advanced in years have their minds pretty much diſturbed: the heat comes on gradually, not burning but dry; the pulſe becomes equal, quick, and large; but the dull pain in the head remains, with a vertiginous affection; the ſkin becomes a little moiſt; and in about four or ſix hours the ſymptoms vaniſh, except a dull pain in the bones, joints, and feet. The urine during the fit is ſometimes thin and watery, ſometimes thick, and depoſits a ſediment.

Sometimes a quartan ague is double, that is, when the fits come on every day at different hours; and it is ſpurious when a paroxyſm begins at any other time of the day than that abovementioned. It is ſaid to be continual when on the intercalary days, there are ſhiverings and pandiculations, with a greater heat than uſual, a quicker pulſe, a want of appetite, a debility, a dryneſs of the mouth, a lightneſs of the head, a diſturbed ſleep, and a reddiſh urine, with a thick roſe-coloured ſediment.

A Quotidian Ague, *or Fever*, returns every day, and is not ſo common as the tertian or quartan.

The acceſſion of this fever is about four or five in the morning, with cold and ſhivering; to which ſucceeds a cardialgic nauſea, and inflation of the belly; in ſome a pain in the head, in others fainting fits; in moſt, vomiting or ſtools, or both: then comes on a moderate heat, with thirſt, but not very intenſe; the pulſe, which was before irregular and weak, becomes more quick, but not very hard; the urine is not of a flame, but rather of a citron colour, and turbid. Some are exceeding ſleepy. At length a moderate ſweat ſupervenes; and in about ten hours the fit goes off, leaving the body dull and heavy.

When this diſeaſe varies from the above deſcription, it is then called ſpurious or anomalous.

From theſe ſymptoms it appears, that the whole nervous ſyſtem is exagitated, and ſuffers greatly by ſpaſtic conſtrictions, which, proceeding chiefly from the medulla ſpinalis, affect preternaturally, not only the coats of the veſſels, but all the fibres throughout the body, and thence greatly diſturb the motion both of the ſolids and fluids.

The material cauſe of this, and all other fevers, is a matter of an active nature, endued with a cauſtic acrimony, which ſolicits the internal and exquiſitely ſenſible parts to ſpaſmodic contractions. It is generated chiefly in the biliary ducts and flexure of the duodenum, where the vitiated, bilious, ſalival, and pancreatic juices, meeting with the crudities of a bad digeſtion, ferment together, and not being timely expelled, become virulent. This matter, paſſing through the lacteals, into the blood, and thence into the nervous parts of the head, medulla ſpinalis, inteſtines, and ſtomach, as alſo to the nervous coats of the excretory and ſecretory ducts, excite an univerſal ſpaſm, which forces the blood, firſt to the interior and greater veſſels; afterwards the ſyſtoltic motion of the heart and arteries being increaſed, the motion of the whole maſs of blood and humours is accelerated, the obſtructions of the ſmall veſſels of the nervous parts are opened; upon which the ſpaſm ceaſing, the excretory ducts are relaxed, the febrile matter paſſes off through the pores of the ſkin by perſpiration or ſweat, and the fit ceaſes, till, by the generation of freſh matter, a new paroxyſm is produced. *Hoffman.*

It appears from the experiments of Langriſh, that the blood in quotidians is more denſe and tenacious than in tertians; and in tertians than in quartans: ſo that in quotidians, cæteris paribus, it comes neareſt to an inflammatory ſtate; and it is commonly obſerved, that if the fever, from a regular tertian, runs into a ſemitertian or quotidian, or greatly anticipates the time of the regular paroxyſm, a remitting or continual fever is ſoon the conſequence.

It is neceſſary to be known, that, from February to Auguſt, fevers are ſaid to be vernal; and from Auguſt to February, autumnal; and, that in the beginning of the autumn, they often reſemble continual fevers, and require a different manner of cure.

No fever emaciates a patient ſooner than a tertian, if attended with a more intenſe and laſting heat. The autumnal and winter agues are obſtinate and hard to cure, eſpecially if there be any fault in the viſcera: on the contrary, the vernal and ſummer agues, if rightly treated, are eaſily vanquiſhed.

Agues, injudiciouſly managed, terminate in cruel and incurable diſeaſes; as a ſlow or hectic fever, a ſudden ſwelling of the feet, a dropſy, œdematous tumours, the jaundice, ſcobutic cachexy, the dry aſthma, the hypochondriac paſſion; and in infants, a fatal epilepſy. Sydenham obſerves, that a ſwelling of the abdomen in children, and of the legs in adults, denotes a ſolution of the diſeaſe; and that a pain in the tonſils, hoarſeneſs, hollow eyes, and a ghaſtly countenance, portend death.

As to the cure, when a load of vitiated humours in the ſtomach and duodenum require depletion, which is known from having indulged in too plentiful eating, from an anxiety of the præcordia, from eructations, and a bitter taſte in the mouth, a vomit of ipecacuanha, after the firſt fit, in the time of intermiſſion, is to be given. If it be an autumnal ague, purging and an emetic may be convenient to prepare the body for the bark, which is eſteemed a ſovereign remedy in this diſtemper; however, it is proper to ſee two or three fits over before the cure of an autumnal ague be attempted with the bark; in vernal agues leſs preparation is neceſſary.

If the bark be good, and freſh powdered, ſix drams, taken in the interval of two fits, are generally ſufficient to ſtop a vernal ague; and an autumnal one will ſeldom require more than an ounce. But though this quantity may remove the fit for the preſent, yet the uſe of the bark muſt be continued for a conſiderable time, to prevent a relapſe. After the fit is ſtopped, two or three doſes a day for the firſt week, and once a day for the ſecond week; and then once in three or four days for a month. In weak conſtitutions, infuſions and decoctions of the bark agree better than the ſubſtance. Some recommend plaiſters and cataplaſms; but theſe are leſs certain. A diarrhæa prevents the effects of the bark, and therefore ſhould be ſtopped with all convenient ſpeed.

When this diſtemper is attended with a quincy, or any great inflammations, obſtructions, or impoſthumes, the bark is dangerous, and ought not to be given before the removal of ſuch ſymptoms.

The cold bath is recommended as one of the laſt things in the cure of an ague: but this is not to be uſed in winter, nor by old or weak perſons. After all other things have proved unſucceſsful, a removal from a cold air to a warmer has performed a cure. *Shaw.*

Ague-tree, a name given by ſome to the ſaſſafras, on account of its febrifuge qualities.

AGUL, in botany, the name of a ſmall prickly podded ſhrub, conſidered by Linnæus as a ſpecies of tredyſarum. Its leaves reſemble thoſe of the knot-graſs; and its flowers are of a reddiſh colour, ſucceeded by red huſks.

AGUARAH, in antiquity, the name of a ſilver coin ſtruck by the Jews, and otherwiſe called gerah and keſhita.

AGUTI, in natural hiſtory, an American quadruped, of the rat kind, greatly reſembling a guinea-pig, both in ſize and ſhape.

The hairs of this creature are rigid and gloſſy, of a mixed colour, between red and brown, with more or leſs black. Its whiſkers are like thoſe of the rabbit kind; but, like the hog, its upper jaw is longer than its lower; and its ſuperior lip ſplit like that of the hare. Its tail is very ſhort, its eyes prominent, and its legs almoſt naked. It has ſix toes with nails on its hinder feet; whereas its fore-feet have only four. When tame it walks on its hinder feet, and takes every thing given it with its fore-feet, like a monkey.

This animal hides itſelf in hollow trees, and feeds on their roots; for which reaſon it is ſeldom very fat, though it never wants food. However, thoſe that are near the plantations live upon fruits, manioc, and potatoes; for which reaſon they are generally fleſhy and well-taſted.

AGYNANI, in eccleſiaſtical hiſtory, a ſect of heretics that appeared in the ſeventh century. They condemned all carnal commerce with women, and pretended that God was not the author of marriage.

The word is Greek, and compounded of α, priv. and γυνη, woman.

AH-AH, in gardening. See the article Hah-hah.

A-HEAD, in navigation, any diſtance before a ſhip, or comprehended on that point of the compaſs to which ſhe ſterns, or points her fore-part; as land a-head, i. e. land lying immediately in that part of the horizon to which the courſe or the ſtern is directed.

AHOVAI, in botany, a genus of pentandrious plants, the flower of which conſiſts of one infundibuliform, or funnel-ſhaped leaf; and its fruit, which, in ſome meaſure, reſembles a pear, contains a triangular kernel. The fruit is poiſonous.

AJAXTIES, in antiquity, were feaſts celebrated at Salamis, in honour of Ajax the ſon of Telamon.

AID, in a general ſenſe, implies any kind of aſſiſtance given by one perſon to another.

Aid, or Ayde, in law, denotes a petition made in court for calling in help from another perſon who has any intereſt in the lands, or other things conteſted.

Aid-de-camp, in military affairs, is an officer employed to receive and carry the orders of a general.

Aid-major, a French term for an ajutant. See Ajutant.

Aid, in ancient cuſtoms, implied a ſubſidy paid by vaſſals to their lord on particular occaſions.

Royal **Aid**, a term uſed by ſome writers to ſignify the land-tax.

Aids, in the menage, are the ſame with what ſome writers call cheriſhings, and uſed to avoid the neceſſity of corrections. The inner heel, inner rein, &c. are called inner aids; as the outer heel, outer rein, &c. are termed outer aids.

AIEREBA, in natural hiſtory, the name of a fiſh, whoſe body forms a regular oval, and its head is placed within the verge of the thinner part.

AIGUA *Marina*. See the article Aqua *Marina*.

AIGUISCE, **Aiguesse**, or **Eguisce**, in heraldry, implies a croſs with its four ends ſharpened, but in ſuch a manner as to terminate in obtuſe angles.

AIR, in philoſophy, is a light, fluid, tranſparent ſubſtance, ſurrounding the earth to a very conſiderable height.

The word is Greek, ἀὴρ, which ſignifies the ſame thing.

Several of the ancients conſidered the air as an element; but it is alſo certain that they uſed the word element in a different ſenſe than we do at preſent.

The air is generally eſteemed a fluid, though it differs from the general nature of fluids in three particulars: 1. In being compreſſible, a property unknown to any other fluid. 2. In being uncongealable, or fixed by any known method, as all other fluids may. 3. In being of a different denſity in every part, decreaſing from the earth's ſurface upwards; whereas other fluids are of an uniform denſity throughout. The air is therefore a fluid ſui generis, if it be properly any fluid at all.

That the air was created at firſt with the earth itſelf, is not to be doubted; and that there has been ever ſince a conſtant generation of particles of air by the mutual action of bodies upon each other, as in fermentations, and all kinds of natural and artificial chemiſtry, Sir Iſaac Newton thinks very reaſonable to ſuppoſe; and Mr. Boyle has given numerous experiments relating to the production of artificial or factitious air.

That the air is a heavy or ponderous body, muſt follow from the nature of the particles of whch it conſiſts; and ſince thoſe particles ariſe from bodies of every kind known in or upon the earth, the conſtituent parts of air muſt be of a very heterogeneous nature, and infinitely various in their ſpecific gravities: whence alſo it will follow, that as the matter which compoſes the body of air, or atmoſphere, is always variable, its weight or gravity will be alſo different, as we conſtantly experience by the barometer. See the article Barometer.

As the particles of air, when ſeparated from bodies beyond the ſphere of corpuſcular attraction, are ſtrongly repelled from thoſe bodies; ſo this repelling power being mutual between the particles, they alſo conſtantly repel each other, and conſequently muſt obſerve an equal diſtance among themſelves: when, therefore, thoſe aerial particles are obliged, by an impreſſed force, to approach nearer to each other, the repulſe of power will react or reſiſt the ſaid force with an equal momentum; and thus cauſe what we call the renitency, elaſticity, or ſpring of the air.

This ſpring of the air muſt render its denſity always different in different altitudes from the earth's ſurface; for the lower parts of the air, being preſſed by the weight of the ſuperior parts, will be made to accede nearer to each other, and the more ſo as the weight of the incumbent air is greater: and hence it follows, that the denſity of the air is greateſt at the earth's ſurface, and decreaſes upwards in geometrical proportion to the altitudes taken in arithmetical progreſſion. See the article Atmosphere.

Since we find, by experience, that the gravity of the air is ſo various, that at one time it will ſuſtain a pillar of mercury 31 inches high, when at another it will raiſe it but to the height of 28 inches, in the barometer; it follows, that we may take $29\frac{1}{2}$ inches of mercury for the mean altitude, and conſequently its weight for the mean weight of a pillar of air of the ſame baſe. But a column of mercury, whoſe baſe is one ſquare inch, and altitude $29\frac{1}{2}$, weighs about 15 ℔, which is equal to the preſſure of air on every ſquare inch; and therefore upon every ſquare foot it will be 2160℔; and allowing $14\frac{1}{2}$ ſquare feet for the ſurface of the body of a middle ſized man, it muſt ſuſtain a preſſure of 31320 pounds, or 14 tons, when the air is of a mean gravity. This prodigious force would cruſh us into a very ſmall compaſs, were it not that it is equal on every part, and counterballanced by the equal re-action of the ſpring of the air within us.

The weight of the air is proved by a great variety of curious experiments, the principal of which here follow: 1. By actually weighing it in a nice ballance, where we ſhall find that one gallon of air will weigh a dram very nearly. 2 By filling a glaſs tube with mercury, and inverting it in a baſon of the ſame fluid, where it will appear that a column will be ſupported in the tube by the ſole weight or preſſure of the air, to upwards the height of 28 inches. 3. By taking the air off from the ſurface of the quick-ſilver in the gage of the air-pump, which then immediately riſes by the preſſure of the external air. 4. By exhauſting a receiver placed over the hole of the braſs plate on the air pump, which will then be kept faſt on by the preſſure of the incumbent air. Or, 5. More demonſtratively, by exhauſting a ſmall receiver under one larger, and letting in the air at once upon it; which will then be faſtened to the plate as before, tho' not placed over the hole. 6. By placing the hand on the open receiver, and exhauſting, the weight of the air on the hand will be extremely ſenſible. 7. By placing a plain piece of glaſs on the ſaid open receiver, which, when the air is a little exhauſted, will be broke into pieces by the weight of the air. 8. A bladder tied over the ſame glaſs will be ſoon broken in the ſame manner.

The ſpring of the air may likewiſe be demonſtrated by various experiments: and it is owing to the preſſure and ſpring of this fluid conjointly, that the great action of human life, we mean inſpiration and expiration, are performed.

Air is alſo a principal cauſe of the vegetation of plants, an inſtance of which we have from Mr. Ray, in the Philoſophical Tranſactions, of lettuce-ſeed that was ſown in the glaſs-receiver of the air-pump, which was exhauſted and cleared from all air, which grew not at all in eight days time; whereas ſome of the ſame ſeed that was ſown at the ſame time, in the open air, was riſen to the height of an inch and an half in that time; but, the air being let into the exhauſted receiver, the ſeed grew up to the height of two or three inches in the ſpace of one week.

Another inſtance of the uſefulneſs of the air in vegetation, is the ſedum, which will puſh out roots without earth and water, and live for ſeveral months: and ſome ſort of aloes, if hung up in a room entirely ſecured from froſts, will remain freſh for ſome years, though they will ſenſibly loſe in their weight.

Air is capable of penetrating the porous and ſpongy parts of plants, and of being there contracted, and of dilating itſelf again.

The air operates alſo within the bowels of the earth, and, by its ſubtility, perſpiring through the pores, aſſiſts in the rarefaction of the crudities of the earth, and in the diſpelling all ſuperfluous moiſture, entering into the very pores and veins of the trees, plants, herbs, &c. carrying along with it thoſe ſalts contained either in itſelf, or lodged in the earth; which ſalts or juices are altered according to the figures or dimenſions of the different ſtrainers or veſſels of thoſe ſeveral plants which grow upon the ſame ſpot of earth, which is ſo impregnated with theſe ſalts: and thence thoſe varieties in taſte and ſmell proceed, notwithſtanding they all receive their nouriſhment from the ſame ſtock that is lodged in the earth.

The air alſo affects the branches, leaves, and flowers of trees, plants, and herbs, entering and perſpiring through them, and even through the bark and body of trees; and by the ſame kind of ſubtility, it does, by its refreſhing breezes, moderate the intenſeneſs of the ſun-beams, cooling, chearing, blowing, opening, and extending all the offspring of nature. The air fixes and inſinuates its aerial ſubſtance into the liquid ſap of vegetables: and, as all the agitations in nature proceed from the contrariety of parts inhabiting together, ſo theſe aerial and liquid ſubſtances being mixed, cauſe the agitation and motion in vegetables, or, more properly, ſet it all into a ferment, whether it be in the roots or in the ſtem; and it riſes by co-operation of the ſun, which is the third agent in vegetation, up to the top of a tree, &c. as liquids riſe by fire to the top of a containing veſſel.

The air we find produces a vibratory motion in ſeveral bodies, and particularly in plants, the air-veſſels thereof perform the office of lungs: for the air contained in them, ſometimes contracting, and ſometimes expanding, according as the heat is increaſed or diminiſhed, preſſes the veſſels, and eaſes them again by turns; and thus promotes a circulation of their juices, which could ſcarce be otherwiſe effected.

Air, ſays the learned Dr. Hales, is a fine elaſtic fluid, with particles of very different natures floating in it, whereby it is admirably fitted by the great Author of nature to be the breath or life of vegetables, as well as animals, without which they can no more live nor thrive than animals can. As a proof of the great quantities of air in vegetables, he refers to his third chapter of his excellent Treatiſe of Vegetable Statics, where, he ſays, in the experiments on vines, the great quantity of air was viſible, which was continually aſcending through the ſap in the tubes; which manifeſtly ſhews what plenty of it is taken in by vegetables, and is perſpired off with the ſap through the leaves.

He adds ſeveral experiments, as to an apple-branch, apricot-branch, birch, and other plants, to prove the ſame thing.

And Dr. Grew has obſerved, that the pores are ſo large in the trunks of ſome plants, as in the better ſort of thick walking canes, that they are viſible to a good eye without a glaſs; but, with a glaſs, the cane ſeems as if ſtuck at top full of holes, with great pins, ſo large as very well to reſemble the pores of the ſkin in the ends of the fingers, and ball of the hand.

In the leaves of vines they likewiſe, through a glaſs, make a very elegant ſhew, ſtanding almoſt exactly in rank and file through the length of the leaves: whence it may be thought probable that the air freely enters plants, not only with the principal fund of nouriſhment by the roots, but alſo through the ſurface of their trunks and leaves, eſpecially at night, when they are changed from a perſpiring to a ſtrongly imbibing ſtate.

Dr. Hales likewiſe tells us, that, in all thoſe experiments he tried to this purpoſe, he found that the air entered very ſlowly at the bark of young ſhoots and branches, but much more freely through old bark; and that in different kinds of trees it had different degrees of more or leſs free entrance.

And likewiſe, that there is ſome air, both in an elaſtic and unelaſtic ſtate, mixed with the earth, (which may well enter the roots with the nouriſhment), he found by ſeveral experiments, which he gives us in the above-mentioned treatiſe.

The excellent Mr. Boyle, in making many experiments on the air, among other diſcoveries, found that a good quantity of air was produceable from vegetables, by putting grapes, plums, gooſeberries, peaſe, and ſeveral other ſorts of fruits and grain, into exhauſted and unexhauſted receivers, where they continued for ſeveral days emitting great quantities of air.

This put the curious Dr. Hales upon further reſearches to find out what proportion of air he could obtain out of the vegetables in which it was lodged and incorporated: this he performed by divers chymico-ſtatical experiments, which he gives in many inſtances, in his Treatiſe of the Analyſis of the Air, plainly ſhewing in what manner he performed them.

One of which was by diſtillation; another by fermentation. That by diſtillation is as follows: the matter to be diſtilled is put into the retort r, (plate IV. *fig.* 1.) and then at a is cemented very faſt the glaſs veſſel $a\ b$, which was very capacious at b, and had an aperture $c\ d$, or hole at the bottom. The bolt-head $a\ b$ being immerſed in water, with one leg of an inverted ſyphon put up as far as z, the water would riſe in the bolt-head, and drive out the air through the ſyphon, which being taken out, the water will remain in the veſſel to the part z: at the ſame time, while the bolt-head is under water, it is placed in the veſſel $x\ x$, which, with the bolt-head and retort, is carried to the chymical furnace, where the retort has the heat and fire gradually communicated to it, and the bolt-head $a\ b$, and veſſel $x\ x$, well ſkreened from the heat of the fire.

As the matter diſtilled, all, except the air, would go down into the water of the bolt-head and veſſel, the air that was generated or deſtroyed by the proceſs, would be ſhewn by cauſing the ſurface of the water in the bolt-head to ſtand below or above the point z, as at y, when all was ſet aſide till it became quite cold. Thus, if the body diſtilling generates air of an elaſtic quality, that added to the former will not permit the water y to riſe ſo high as z, and the ſpace between z and y below will ſhew how much air was produced from its fixed ſtate.

But if, when all is cold, the ſurface of the water y be ſeen above the point z; it then ſhews that the diſtilled body did deſtroy, that is, imbibe or abſorb, a part of the natural air above z; and the ſpace between z and y, filled with water, will ſhew what quantity was changed from a repellent elaſtic to a fixed ſtate, by the ſtrong attraction of the abſorbing particles of the diſtilled body. This quantity of generated or abſorbed air it is eaſy to meaſure in cubic inches, by ſtopping the end of the bolt-head with a cork, and then from a quantity of water of a known weight, to fill it firſt to z, and afterwards to y; and the difference of weight in the two bulks of water gives the number of cubic inches, from a table of ſpecific gravities.

The other method which the doctor made uſe of for eſtimating the ſurpriſing effects of fermentation, from various mixtures of ſolid and fluid ſubſtances in generating and abſorbing air, was as follows: he put the ingredients into the bolt-head b, (*fig.* 2.) and then run the long neck thereof into a tall cylindric glaſs $a\ y$, and inclining both almoſt horizontally, in a large veſſel of water, the water ran into the veſſel $a\ y$, and, driving out part of the air, would poſſeſs its place upon turning them up, and placing both in a veſſel of water $x\ x$, as you ſee in the figure, where the ſurface of the water ſtands in the inverted glaſs $a\ y$ at the point z.

If the ingredients generated air, then the water would fall from z to y, and the empty ſpace $z\ y$ was equal to the quantity of generated air; but if, on fermentation, they abſorbed or fixed the active particles of air, then the ſurface of the water would aſcend from z to n; and the cylinder $z\ n$ would be the bulk of air abſorbed, which is eaſily known in cubic inches.

When the ſubjects for trying theſe experiments were a burning candle, burning brimſtone, nitre, gun-powder fired, living animals, &c. the Doctor uſed to make uſe of a pedeſtal, on the top of which was a plate, whereon he laid the matter to be fired; then inverting the tall cylindric glaſs over it, and drawing the water up to $z\ z$ (*fig.* 3.) with an inverted ſyphon, he ſet fire to the matters lying on the plate, by means of a burning glaſs, concentering the ſun's rays in its focus upon the ſame. See the *figure*.

But the beſt way is, inſtead of having the cylindric glaſs cloſe upon the top of $b\ b$, to have it open by a ſmall neck, on which a braſs cap is cemented with a female-ſcrew to receive a ſtop-cock, to take off the communication of the external air, when occaſion requires. Thus the uſe and trouble of the ſyphon is ſuperſeded; and in caſe of noxious fumes, vapours, &c. from aquafortis, burning brimſtone, &c. a ſyringe ſcrewed on to the ſtop-cock will draw off the air, and raiſe the water to what height you pleaſe, without the cumberſome uſe of a large pair of bellows, as the doctor made uſe of.

From half a cubic inch, or 135 grains of heart of oak, freſh cut from a growing tree, he found there were 108 cubic inches of air generated, which is a quantity equal to 216 times the bulk of the piece of oak; that the weight of it was above 30 grains, one quarter part of the weight of 135 grains.

And he adds, that he took the like quantity of thin ſhavings from the ſame piece of oak, and dried them at ſome diſtance from a gentle fire, for 24 hours; in which time they evaporated 44 grains of moiſture; which 44 grains being deducted from 135 grains, there remain 91 grains for the ſolid part of the oak: then 30 grains will be one-third of the weight of the ſolid part of the oak.

He gives us another experiment of Indian wheat, which grew in his own garden: he took 388 grains of it, when it was not come into its full maturity, and there were generated from it 270 cubic inches of air; the weight of which air was 77 grains, viz. one-fourth of the whole weight of the wheat.

He alſo found that a cubic inch, or 318 grains, of peaſe generated 396 cubic inches of air, or 113 grains, i. e. ſomething more than one third of the weight of the peaſe.

And again, that from one ounce, or 437 grains, of muſtard ſeed, 270 cubic inches of air were generated, or 77 grains, which is more than one-ſixth part of the ounce weight.

He likewiſe adds, that there is a great plenty of air incorporated into the ſubſtance of vegetables, which, by the action of fermentation, is rouzed into an elaſtic ſtate, as is evident from theſe experiments following.

On the ſecond day of March he poured 42 cubic inches of ale from the tun, which had been there ſet to ferment 34 hours before, into a bolt-head; and from that time, to the 9th of June, it generated 639 cubic inches of air, with a very unequal progreſſion, more or leſs, as the weather was warm, cool, or cold; and ſometimes, upon a change from warm to cool, it reſorbed air, in all 32 cubic inches.

From the ſecond of March to the 16th of April, 12 cubic inches of Malaga raiſins, with 18 cubic inches of water, generated 411 cubic inches of air; and then, again, it reſorbed 35 cubic inches in two or three cold days. From the 21ſt of April, to the 16th of May, it generated 78 cubic inches; after which, the 9th of June, it continued in a reſorbing ſtate, ſo as to reſorb 13 cubic inches: that there were at that ſeaſon many hot days, with much thunder and lightning, which deſtroy the elaſticity of the air: there were generated in all 489 cubic inches, of which 48 were abſorbed. The liquor was at laſt vapid.

On the 10th of Auguſt, 26 cubic inches of apples being maſhed, they generated 986 cubic inches of air in 13 days time, which is a quantiny equal to 48 times their bulk; after which they reſorbed a quantity equal to their bulk, in three or four days, notwithſtanding the weather was then very hot; after which time they were ſtationary for many days, neither generating nor abſorbing.

From the abovementioned experiments on raiſins and ale, the ingenious author concludes, that wine and ale do not turn vapid in warm weather, by imbibing the air, but by fermenting and generating too much; by which means they are deprived of their enlivening principle, the air: for which reaſon, theſe liquors are beſt preſerved in cool cellars, whereby this active invigorating principle is kept within due bounds, which, when they exceed, wines are upon the fret, and are in danger of being ſpoiled. Upon theſe, and many other experiments, which the learned author has given in his aforeſaid treatiſe, he obſerves, that the air, which ariſes in ſo great quantities from fermenting and diſſolving vegetables, is true permanent air; which is certain, by its continuing in the ſame expanded and elaſtic ſtate for many weeks and months, which expanded watery vapours will not do, but ſoon condenſe when cold.

Upon the whole, he concludes, that air abounds in vegetable ſubſtances, and bears a conſiderable part in them: and, if all the parts of matter were only endowed with a ſtrongly attracting power, all nature would then immediately become one inactive cohering lump.

Wherefore it was abſolutely neceſſary, in order to the actuating this vaſt maſs of attracting matter, that there ſhould be every where mixed with it a due proportion of ſtrongly repelling elaſtic particles, which might enliven the whole maſs by the inceſſant action between them and the attracting particles.

And ſince theſe elaſtic particles are continually in great abundance reduced by the power of the ſtrong attracters, from an elaſtic to a fixed ſtate, it was therefore neceſſary that theſe particles ſhould be indued with a property of reſuming their elaſtic ſtate, whenever they were diſengaged from that maſs in which they were fixed, that thereby this beautiful frame of things might be maintained in a continual round of the production and diſſolution of vegetable, as well as animal, bodies.

The air is very inſtrumental in the production and growth of vegetables, both by invigorating their ſeveral juices, while in an elaſtic active ſtate; and alſo by greatly contributing, in a fixed ſtate, to the union and firm connection of the ſeveral conſtituent parts of thoſe bodies, viz. their water, fire, ſalt, and earth.

In ſhort, the air before mentioned, is very ſerviceable to vegetables, in that it blows up and breaks open the clouds, whoſe treaſures of rain nouriſh the vegetable tribe.

The air alſo helps to waft or diſperſe thoſe foggy humid vapours which ariſe from the ſoil, and would otherwiſe ſtagnate and poiſon the whole face of the earth.

The air, by the aſſiſtance of the ſun, aſſumes and ſublimates thoſe vapours into the upper regions; and thoſe foggy humid vapours are, by this ſublimation, and the coercive power of the air and ſun, rarefied, and made again uſeful in vegetation.

And, on the contrary, to the benign quality of the air, which is ſo many ways ſubſervient to vegetables, it is alſo ſometimes, and upon ſome accounts, injurious and pernicious to them; not only to the ligneous, herbaceous, and flowery parts above, but alſo to the roots and fibres below: for, becauſe the air penetrates into the earth, it is eaſy to be concluded, that a dry, huſky, ſcorching air, may be very prejudicial to the tender fibres of new planted trees.

It may be likewiſe ſuppoſed, that all bodies of earth are more or leſs capable of imbibing the fluid air, and of attracting ſuch ſalts as either can give, or the earth is capable of receiving.

In chemiſtry, it is by no means indifferent whether the proceſs be made in the air or out of it, whether in a confined or open air. Thus camphire, burnt in a cloſe-ſtopped veſſel, goes all into ſalts; inſtead of which, during the proceſs, if you open the veſſel and approach it with a wax taper, it all diſſipates into ſmoke. In like manner, to make ſulphur inflammable, there muſt be an open air. In a cloſe cucurbit, you may ſublimate it even a thouſand times without its taking fire. If ſulphur be put under a bell glaſs, with fire underneath it, a ſpirit of ſulphur will ariſe; but, if there be the leaſt crack in the glaſs, to permit a communication between the interior and exterior air, the ſulphur will immediately take fire. An ounce of charcoal, incloſed in a well-luted crucible, will remain there, without decay, fourteen or fifteen days in the middle of a furnace with a ſtrong fire; though in open air, the thouſandth part of fire would have reduced it into aſhes in a minute. Van Helmont even adds, that all this time the charcoal keeps its black colour; but, on the intermiſſion of a little air, it immediately changes into white aſhes. The ſame thing may be ſaid of all animal and vegetable ſubſtances, which can only be calcined in open fire; but in ſtopped veſſels can only be reduced to black coals.

The air can effect infinite mutations in ſubſtances, not only with regard to its mechanical properties, as gravity, denſity, &c. but alſo on account of the heterogeneous parts which enter into all ſubſtances; as, for example, where there is a great many, the air is impregnated with a biting vitriolic ſalt, which deſtroys every thing on the earth round about, and frequently appears on the ſurface of the ground in a kind of whitiſh effloreſcence.

At Fohlun, in Sweden, a town famous for its copper mines, which have procured it the name of Copperburg, the mineral exhalations affect the air ſo ſenſibly, that the ſilver and copper money people carry in their pockets, changes colour by the means of it: and Mr. Boyle was informed, by a gentleman of property in thoſe parts, that from the veins of metals and minerals, frequent in that country, columns of a kind of ſmoke or ſteam frequently ariſe, ſome of which had a very bad ſcent, others none at all, and ſome an agreeable one. In Carniole and other places, where there are mines, the air is at ſome ſeaſons very unhealthy, from whence proceed ſeveral epidemical diſtempers. We ſhall add, that, about the Cape of Good Hope, the mines of arſenic, which are numerous in

that neighbourhood, emit ſuch noxious vapours, that no animal can live, and they were therefore obliged to ſhut them up again, after having been opened for ſome time.

Dr. Hales has lately contrived a machine, which he calls a ventilator, for evacuating foul air. See the article VENTILATOR.

We are not yet ſufficiently acquainted of what importance it is, that the air we breathe ſhould be pure and free from all mixture of nauſeous and offenſive particles; but, if ſuch a quality of air is ſo much to be deſired by every body, how much more eſſentially neceſſary is it for thoſe whom ſickneſs has made ſuſceptible of every external impreſſion, and thoſe who, pent up in a ſhip, during the courſe of a long voyage, are obliged to live between decks, and are forced to hard labour in different places of the lower parts of the veſſel, which receive very little air from without, and where it is always motionleſs, and, as it were, ſtagnated?

What renders this ſtill more deplorable, is thoſe very places into which we would chooſe to have pure air, are in general filled with the contrary: the air of hoſpital-rooms is almoſt always mixed with the vapours that continually exhale from the bodies of the ſick, their cloſe-ſtools, and the different remedies adminiſtered to them: the terrible ſickneſſes ſome people of the ſtrongeſt conſtitutions have been attacked with, on their entering into theſe places at firſt, are a proof, paſt contradiction, of the impurity of the air, and its effects.

The ſame thing happens in ſhips, where the exhalations that ariſe from the proviſions, from the pores of the men and living creatures on board, produce effects nearly like to thoſe obſerved in hoſpitals.

In order to prevent the accidents which air mixed with theſe noxious vapours may occaſion more certainly, it will be right, firſt, to examine into the nature of theſe vapours. The leaſt attention will convince us they are almoſt entirely volatile; we muſt conclude, therefore, they will always naturally riſe toward the cieling of the rooms, and this motion, upward, muſt be increaſed by the motion of the air, which aſcends in proportion to its rarefaction.

If this propoſition wanted proof, it is eaſy to demonſtrate it: only raiſe a ladder againſt the wall of a room in an hoſpital, and you will find, as you advance towards the cieling, the ſmell, which you could ſupport below, grow continually more offenſive, and the air hotter; this being admitted, it will be eaſy to let out the foul air, and introduce freſh, only by placing windows cloſe under the cieling, and leaving the top ſquares always open; for the hot and putrified air would continually go off, and a circulation of freſh air be promoted every moment.

The ſame effect might be produced by erecting a cupola, or dome, at each extremity of a ward in an hoſpital; the air would naturally be drawn to them, and paſs off by them: this has been practiſed at Lyons, with ſo much ſucceſs, that you can ſcarce perceive any ſmell at all in the hoſpital; but, if you ſhould go on the inſide of the cupola, the ſtench is inſufferable.

AIR, in medicine, makes one, and not the leaſt powerful, of the non-naturals; as upon it the very life of animals depends.

It is ſuſceptible of different qualities; hot, moiſt, cold, dry, ſerene, pure, and temperate. It is ſubject to variations, more or leſs ſudden, and to be mixed with impure, corrupted, contagious, metallic, ſulphureous exhalations, which are all prejudicial to health. The beſt quality of the air is to be pure and ſweet, void of all bad exhalations, neither too hot, cold, dry, nor moiſt.

The ſudden changes of the air are inevitable and dangerous; whence proceed a great number of diſeaſes, which reign in the ſpring and autumn, towards the approach of winter. Hoſpitals, camps, places where lead is melted, and the earth juſt thrown up, are generally unhealthy, on account of the bad exhalations. Lighted charcoal, in a cloſe place, fills the air with ſulphureous particles, which are unwholeſome, and ſometimes kill the ſtrongeſt perſons.

Too hot an air diſpoſes to malignant fevers; if it be without moiſture, it produces diary and putrid fevers. Agues are epidemic in the fens of Cambridgeſhire, the hundreds of Eſſex, and in ſome parts of Kent, on account of the vapours which weaken the fibres of the body, and obſtruct the pores of the ſkin; beſides, a cold and moiſt conſtitution of the air produces coughs, diſtillations, and rheumatic pains.

Hectic and conſumptive people are in great danger, both in very hot and in very cold weather. When the paſſage through the pores of the ſkin is ſtopt by cold, the patient is either apt to fall into a looſeneſs, or to have his legs ſwelled, and the aſthmatic ſymptoms increaſed.

AIR, in mythology, was worſhipped by the pagans, under the names of Jupiter and Juno; the former repreſenting the ſuperior and finer part of the atmoſphere, and the latter the inferior and groſſer part.

AIR, in painting and ſculpture, denotes the manner and very life of action; or, it is that which expreſſes the diſpoſition of the agent. See ACTION.

Some uſe the word to ſignify the geſture or attitude of a figure.

AIR, in muſic, implies the melody proper for ſongs, odes, &c. being uſually quick and lively.

The term is ſometimes uſed to ſignify the ſongs themſelves, called by the Romans, *æra*, whence the word in this acceptation is derived.

AIRS, in the manege, ſignify the artificial motions of taught or managed horſes; ſuch as the demi-volt, curvet, capriole, &c.

Some extend the term to the natural paces of a horſe, as walking, trotting, galloping; but this is not a proper application of the word, and is accordingly never uſed in the latter ſenſe by the beſt writers.

AIR-BLADDER, a veſicle found in the bodies of all fiſhes except thoſe of the cartilaginous and cetaceous kinds. It is vulgarly called the ſwim, or ſwimming bladder.

By the aſſiſtance of this bladder, which is always more or leſs replete with air, the fiſh is enabled to ſuſtain its body at any depth. When the fiſh is near the bottom, the great weight of the incumbent water compreſſes its body, or rather the incloſed air-bladder, till the whole fiſh becomes equiponderant with an equal bulk of water. In the middle of the fluid, where the preſſure is leſs, the air-bladder expands; thereby increaſes the bulk of the fiſh, without adding any thing to its weight, till it here alſo becomes equiponderant with an equal bulk of water: and in this manner the air-bladder expands, as the fiſh riſes nearer the ſurface, and by that means ſuſtains it at any depth.

There is however no doubt but fiſhes have a power of expanding and compreſſing the air-bladder, excluſive of the weight of the water, and by that means of riſing or ſinking at pleaſure.

Some fiſhes have only a ſingle air-bladder; ſome a double one; and in others it is triple, or divided into three cells. Fiſhes which lie groveling at the bottom, have no air-bladders; and it is remarkable, that if the air-bladder be either pricked or burſt, in fiſhes naturally furniſhed with it, they immediately ſink to the bottom; from whence they can never riſe themſelves.

AIR-GUN, a pneumatic machine for exploding bullets, &c. with great violence.

The common air-gun is made of braſs, and has two barrels; the inſide barrel A (pl. II. *fig.* 1) is of a ſmall bore, from whence the bullets are exploded; and a large barrel ECDR on the outſide of it. There is a ſyringe SMNP fixed in the ſtock of the gun, by which the air is injected into the cavity between the two barrels thro' the valve EP. The ball K is put down into its place in the ſmall barrel, with the rammer, as in another gun. At SL is another valve, which, being opened by the trigger O, permits the air to come behind the bullet, ſo as to drive it out with great force. If this valve be opened and ſhut ſuddenly, one charge of condenſed air may be ſufficient for ſeveral diſcharges of bullets; but if the whole air be diſcharged on one ſingle bullet, it will drive it out with a great force. This diſcharge is effected by means of a lock (*fig.* 2.) placed here as uſual in other guns; for the trigger being pulled, the cock will go down and drive the lever O (*fig.* 1.) which will open the valve, and let in the air upon the bullet K.

The magazine air-gun is the invention of that ingenious artiſt L. Colbe. By this contrivance ten bullets are ſo lodged in a cavity, near the place of diſcharge, that they may be drawn into the ſhooting barrel, and ſucceſſively diſcharged ſo faſt as to be nearly of the ſame uſe as ſo many different guns.

Fig. 3. repreſents the preſent form of this machine, where part of the ſtock is cut off, to the end of the injecting ſyringe. It has its valve opening into the cavity between the barrels, as before. KK is the ſmall ſhooting-barrel, which receives the bullets from the magazine ED, which is of a ſerpentine form, and cloſed at the end D, when the bullets are lodged in it. The circular part *s* I *sk* M *i*, is the key of a cock, having a cylindric hole through it IK, which is equal to the bore of the ſame barrel, and makes a part of it in the preſent ſituation. When the lock is taken off, the ſeveral parts Q, R, T, W, &c. come into view, by which means the diſcharge is made by puſhing up the pin P*p*, which raiſes and opens a valve V, to let in the air againſt the bullet I, from the cavity F, F, F; which valve is immediately ſhut down again by means of a long ſpring of braſs N. This valve V being a conical piece of braſs, ground very true in the part which receives it, will of itſelf be ſufficient to confine the air.

To make a diſcharge, you will pull the trigger ZZ, which throws up the ſeer *yx*, and diſengages it from the notch *x*, upon which the ſtrong ſpring WW moves the tumbler T, to which the cock is fixed. This, by its end *u*, bears down the end *v* of the tumbling lever R, which, by the other end *m*, raiſes at the ſame time the flat end *l* of the horizontal lever Q; and by this means of courſe, the pin P*p* is puſhed up, which ſtands upon it, and thus opens the valve V, and diſcharges the bullet. This is all evident from a bare view of the figure.

To bring another bullet to ſucceed that marked I, inſtantaneouſly, turn the cylindric cavity of the key of the cock, which before made part of the barrel KKK, into the ſituation *ik*, ſo that the part I may be at K, and holding the gun upon your ſhoulder, with the barrel downwards, and the magazine upwards, by which means that bullet next the cock will fall into it out of the magazine, but go no farther into this cylindric cavity than the two little ſprings *ss*, which detains it. The two circles repreſent the cock barrel, wherein the key abovementioned turns upon an axis not repreſented here, but viſible in *fig.* 4. This axis is a ſquare piece of ſteel, on which comes the ſquare hole of the hammer H; by which the cylindric cavity mentioned is opened to the magazine. Then opening the hammer, as in *fig.* 5. the bullet is brought into its proper place near the diſcharge valve, and the cylindric cavity of the key of the cock again makes part of the inward barrel KKK.

It evidently appears how expeditious a method this is of charging and diſcharging a gun; and were the force of condenſed air equal to that of gunpowder, ſuch an air-gun would anſwer the end of ſeveral guns.

In the air-gun, and all other caſes where the air is required to be condenſed to a very great degree, it will be requiſite to have the ſyringe of a ſmall bore, viz. not exceeding half an inch in diameter; becauſe the preſſure againſt every ſquare inch is about 15 pounds, and therefore againſt every circular inch about 12 pounds. If therefore the ſyringe be one inch in diameter, when one atmoſphere is injected, there will be a reſiſtance of 12 pounds againſt the piſton; and when ten are injected, there will be a force of 120 pounds to be overcome; whereas ten atmoſpheres act againſt the circular half-inch piſton (whoſe area is only one fourth part ſo big) with only a force equal to 30 pounds; or 40 atmoſpheres may be injected with ſuch a ſyringe as well as 10 with the other. In ſhort, the facility of working will be inverſely, as the ſquares of the diameter of the ſyringe.

AIR-JACKET, a ſort of jacket made of leather, in which are ſeveral bags, or bladders, compoſed of the ſame materials, communicating with each other. Theſe are filled with air through a leather tube, having a braſs ſtop-cock accurately ground at the extremity, by which means the air blown in through the tube is confined in the bladders. The jacket muſt be wet, before the air be blown into the bags, as otherwiſe it will immediately eſcape through the pores of the leather. By the help of theſe bladders, which are placed near the breaſt, the perſon is ſupported in the water, without making the efforts uſed in ſwimming; and conſequently may ſave himſelf, if he has the misfortune of falling over-board, &c. See the article CORK-JACKET, where the reader will find a compariſon between theſe two inventions.

AIR-PUMP, a pneumatic machine, by which the air contained in a proper veſſel may be exhauſted.

The inventor of this noble inſtrument was the celebrated Otto de Guerick, a burgomaſter of Magdeburg, who performed ſeveral experiments on it at Ratiſbon, before the emperor and ſeveral other perſons of diſtinction, in the year 1654. But this inſtrument was very defective, it requiring the labour of two ſtrong men, for above two hours, to exhauſt the air out of glaſs veſſels, plunged under water. Some time after Mr. Boyle, with the aſſiſtance of Dr. Hook, contrived a new air-pump; more commodious and better adapted to experiments than that of the German author; and hence, the inſtrument was called Machina Boyleana.

Several ſorts of air-pumps have been from time to time conſtructed, and ſeveral improvements made in this uſeful machine at different times and by different perſons. The following, which is generally in uſe, was publiſhed by Mr. Hawkſbee, in the year 1709.

Deſcription of the common AIR-PUMP. This machine is repreſented on plate II. *fig.* 6. where A, A, are two braſs barrels, in which the piſtons C, C, move up and down by means of a cog wheel, which moves on the axis F, when the machine is put in motion by the winch B. G, G, are two pillars, or pieces of wood, ſupporting the frame of the pump-wheel, which is ſcrewed upon them by nuts under the little pieces of wood E, E. The braſs tube, or pipe, marked H, H, is called the ſwan-neck; by this the air paſſes from under the receiver O, O, through a ſmall hole K, in the middle of the braſs plate I, I, on the top of the pump to a braſs piece in the box D, D, which being perforated lengthways, to the middle point, under each barrel, tranſmits the air through a ſmall hole by a bladder valve, from the receiver to each barrel, to be pumped out by paſſing through the hole in the deſcending piſton. Theſe holes in the piſtons, and bottoms of the barrels, are covered with valves to prevent the return of the air into the receiver. The mercurial gauge, or common barometer, marked L, L, is immerſed in a baſon of mercury, fixed in the bottom of the frame, and at the top communicates with the receiver, and conſequently ſhews how much the receiver is exhauſted by the riſing of the mercury in the tube, by a graduated ſcale fixed to it. Under the frame, below K, is a ſtop-cock communicating with the receiver, by turning which the air will be re-admitted. The receiver is ground very true at the bottom, and fixed on the pump by means of wetted leathers, by which means the air is effectually excluded.

Deſcription of a portable AIR-PUMP. This pump is repreſented on plate II. *fig.* 7, where A, B, is the head, or part containing the wheel, which alternately riſes and depreſſes the piſtons C, D, in the barrels E F, which are ſtrongly preſſed down by the ſaid part A, B, ſupported by the two pillars G, H, fixed into the bed or bottom I, K, L, of the machine. On this bottom ſtands the receiver M, N, on a large, ſmooth, braſs plate, in the middle of which is a hole, by which the air paſſes out of the receiver into a ſmall tube on the under part of the frame, and goes to the piece O, which communicates with the perforated braſs piece on which the barrels ſtand, and from which they receive the air to be exhauſted: on the middle part of this braſs piece is a perforation, over which is placed a ſmall receiver P, Q, and under it a baſon of mercury R, in which a ſmall tube R, S, hermetically ſealed at one end, and filled with quickſilver, is inverted; and conſequently, as the ſmall receiver P Q is exhauſted, together with the large one M, N, the approach of the vacuum will be indicated by the deſcent of the quickſilver in the tube R, S. By means of a ſtop-cock at T, the air is again let into the receiver.

Deſcription of Mr. Smeaton's AIR-PUMP. This ingenious gentleman has not only obliged the world with an air-pump, far preferable to any machine of that kind

hitherto known; but alſo ſhewn the reaſons on which the imperfections of the common air-pump depend. The reader will therefore, we are perſuaded, be pleaſed to ſee Mr. Smeaton's obſervations in his own words.

"The principal cauſes of imperfection in the common pumps ariſe, firſt, from the difficulty in opening the valves at the bottom of the barrels; and, ſecondly, from the piſton's not fitting exactly, when put cloſe down to the bottom, which leaves a lodgment for air, that is not got out of the barrel, and proves of bad effect.

"In regard to the firſt of theſe cauſes, the valves of air pumps are commonly made of a bit of thin bladder, ſtretched over a hole generally much leſs than one tenth of an inch diameter; and to prevent the air from repaſſing between the bladder and the plate, upon which it is ſpread, the valve muſt always be kept moiſt with oil or water.

"It is well known, that at each ſtroke of the pump the air is more and more rarefied, in a certain progreſſion, which would be ſuch, that an equal proportion of the remainder would be taken away, was it not affected by the impediments I have mentioned: ſo that, when the ſpring of the air in the receiver becomes ſo weak, as not to be able to overcome the coheſion of the bladder to the plate, occaſioned by the fluid between them, the weight of the bladder, and the reſiſtance that it makes by being ſtretched, the rarefaction cannot be carried farther, tho' the pump ſhould ſtill continue to be worked.

"It is evident, the larger the hole is, over which the bladder is laid, a proportionably greater force is exerted upon it by the included air in order to lift it up; but the aperture of the hole cannot be made very large, becauſe the preſſure of the incumbent air would either burſt the valve, or ſo far force it down into the cavity, as to prevent its lying flat and cloſe upon the plate, which is abſolutely neceſſary.

"To avoid theſe inconveniences as much as poſſible, inſtead of one hole, I have made uſe of ſeven, all of equal ſize and ſhape; one being in the center, and the other ſix round it: ſo that the valve is ſupported at proper diſtances by a kind of grating, made by the ſolid parts between theſe holes: and, to render the points of contact, between the bladder and grating, as few as poſſible, the holes are made hexagonal, and the partitions filed almoſt to an edge. As the whole preſſure of the atmoſphere can never be exerted upon this valve, in the conſtruction made uſe of in this pump; and, as the bladder is faſtened in four places inſtead of two, I have made the breadth of the hexagons three tenths of an inch; ſo that the ſurface of each of them is more than nine times greater than common. But as the circumference of each hole is more than three times greater than common, and as the force that holds down the valve, ariſing from coheſion, is, in the firſt moment of the air's exerting its force, proportionable to the circumference of the hole; the valve over any of theſe holes will be raiſed with three times more eaſe than common: but as the raiſing the valve over the center-hole is aſſiſted on all ſides by thoſe placed round it, and as they altogether contribute as much to raiſe the bladder over the center-hole, as the air immediately acting under it; upon this account the valve will be raiſed with double the eaſe that we have before ſuppoſed, or with a ſixth part of the force commonly neceſſary.

"It is not material to conſider the force of the coheſion, after the firſt inſtant: for, after the bladder begins to riſe, it expoſes a greater ſurface to the air underneath, which makes it move more eaſily. I have not brought into this account, the force that keeps down the valve, that ariſes from the weight of the bladder, and the reſiſtance from its being ſtretched; for I look upon theſe as ſmall in compariſon of the other.

"I was not, however, contented with this conſtruction of the valves, till I had tried what effect would be produced, when they were opened by the motion of the winch, independent of the ſpring of the air: and though the contrivance I made uſe of ſeemed to me leſs liable to objection than any thing I was acquainted with, that had been deſigned for that purpoſe; yet I did not find it to anſwer the end better than what I have already deſcribed; and therefore laid it aſide, as it rendered the machinery much more complex, and troubleſome to execute.

"But, ſuppoſing all thoſe difficulties to be abſolutely overcome, the other defect, that I mentioned in the common conſtruction, would hinder the rarefaction from being carried on beyond a certain degree. For, as the piſton cannot be made to fit ſo cloſe to the bottom of the barrel, as totally to exclude all the air, as the piſton riſes, this air will expand itſelf; but ſtill preſſing upon the valve according to its denſity, hinders the air within the receiver from coming out: hence, were this vacancy to equal the 150th part of the capacity of the whole barrel, no air could ever paſs out of the receiver, when expanded 150 times, though the piſton was conſtantly drawn to the top; becauſe the air in the receiver would be in æquilibrio with that in the barrel, when in its moſt expanded ſtate. This I have endeavoured to overcome, by ſhutting up the top of the barrel with a plate, having in the middle a collar of leathers, through which the cylindrical rod works that carries the piſton. By this means the external air is prevented from preſſing upon the piſton; but that the air that paſſes through the valve of the piſton from below may be diſcharged out of the barrel, there is alſo a valve applied to the plate at the top that opens upwards. The conſequence of this conſtruction is, that, when the piſton is put down to the bottom of the cylinder, the air in the lodgment under the piſton will evacuate itſelf ſo much the more, as the valve of the piſton opens more eaſily, when preſſed by the rarefied air above it, than when preſſed by the whole weight of the atmoſphere. Hence, as the piſton may be made to fit as nearly to the top of the cylinder, as it can to the bottom, the air may be rarefied as much above the piſton as it could before have been in the receiver. It follows, therefore, that the air may now be rarefied in the receiver, in duplicate proportion of what it could be upon the common principle; every thing elſe being ſuppoſed perfect. Another advantage of this conſtruction is, that though the pump is compoſed of a ſingle barrel, yet the preſſure of the outward air being taken off by the upper plate, the piſton is worked with more eaſe than the common pumps with two barrels; and not only ſo, but when a conſiderable degree of rarefaction is deſired, it will do it quicker; for the terms of the ſeries expreſſing the quantity of air taken away at each ſtroke, do not diminiſh ſo faſt as the ſeries anſwering to the common one.

"I have found the gauges that have been hitherto made uſe of for meaſuring the expanſion of the air, very unfit to determine in an experiment of ſo much nicety. I have therefore contrived one of a different ſort, which meaſures the expanſion with certainty, to much leſs than the 1000th part of the whole. It conſiſts of a bulb of glaſs ſomething in the ſhape of a pear, and ſufficient to hold about half a pound of quickſilver. It is open at one end, and at the other is a tube hermetically cloſed at top. By the help of a nice pair of ſcales, I found what proportion of weight a column of mercury, of a certain length, contained in the tube, bore to that which filled the whole veſſel. By theſe means I was enabled to mark diviſions upon the tube, anſwering to the 1000th part of the whole capacity, which, being of about one tenth of an inch each, may by eſtimation, be eaſily ſubdivided into ſmaller parts. This gauge during the exhauſting of the receiver, is ſuſpended therein by a ſlip-wire. When the pump is worked as much as ſhall be thought neceſſary, the gauge is puſhed down, till the open end is immerged in a ciſtern of quickſilver placed underneath: the air being then let in, the quickſilver will be driven into the gauge, till the air remaining in it becomes of the ſame denſity with the external; and as the air always takes the higheſt place, the tube being uppermoſt, the expanſion will be determined by the number of diviſions occupied by the air at the top. The degree, to which I have been able to rarefy the air in experiment, has generally been about 1000 times, when the pump is put clean together; but the moiſture that adheres to the inſide of the barrel, as well as other internal parts, upon letting in the air, is in the ſame ſucceeding trials worked together with the oil, which ſoon renders it ſo clammy as to obſtruct the action of the pump upon a fluid ſo ſubtile as the air is, when ſo much expanded; but in this caſe it ſeldom fails to act upon the air in the receiver, till it is expanded 500 times: and this I have found it to do, after being frequently uſed for ſeveral months without cleaning. I have alſo generally found it to perform beſt the firſt trial at each time of uſing, though nothing had been at it from the time preceding; which, after a great many trials made with this view, I alſo attribute to the vapours of the air mixing with the oil. An experiment, where the air was expanded 1000 times, was tried about two years ſince in preſence of the Royal Society; at which were preſent alſo Dr. Knight and Mr. Canton; and I lately did the ſame thing with Mr. Watſon. The pump, which I intend myſelf the honour of ſhewing the Society, is the ſame that I juſt now mentioned; and the ſecond that I made, with a view to improve upon this principle.

" The degree of rarefaction, produced by the beſt of the three pumps, that you procured the trial of, and which you eſteemed good in their kind, and in complete order, never exceeded 140 times, when tried by the gauge before deſcribed.

" I have alſo endeavoured to render the pneumatic apparatus more ſimple and commodious, by making this air-pump act as a condenſing engine at pleaſure, by ſingly turning a cock. This not only enables us to try any experiments under different circumſtances of preſſure, without changing the apparatus, but renders the pump an univerſal engine, for ſhewing any effect that ariſes from an alteration in the denſity or ſpring of the air. Thus, with a little addition of apparatus, it ſhews the experiments of the air-fountain, wind-gun, &c.

" This is done in the following manner: the air above the piſton, being forcibly driven out of the barrel at each ſtroke, and having no where to eſcape, but by the valve at the top; if this valve be connected with the receiver, by means of a pipe, and at the ſame time the valve at the bottom, inſtead of communicating with the receiver, be made to communicate with the external air, the pump will then perform as a condenſer.

" The mechaniſm is thus ordered: there is a cock with three pipes placed round it, at equal diſtances; the key is ſo pierced that any two may be made to communicate, while the other is left open to the external air. One of theſe pipes goes to the valve at the bottom of the barrel; another goes to the valve at the top, and a third goes to the receiver. Thus, when the pipe from the receiver, and that from the bottom of the barrel, are united, the pump exhauſts; but turn the cock round, till the pipe from the receiver, and that from the top of the barrel, communicate, and it then condenſes. The third pipe, in one caſe, diſcharges the air taken from the receiver into the barrel; and, in the other, lets it into the barrel, that it may be forced into the receiver.

" Plate III. *fig.* 1. is a perſpective view of the principal parts of the pump together. A is the barrel. B the ciſtern, in which are included the cock, with ſeveral joints. Theſe are covered with water to keep them air-tight. A little cock to let the water out of the ciſtern, is marked 6. C *cc* is the triangular handle of the key of the cock; which, by the marks on its arms, ſhews how it muſt be turned, that the pump may produce the effect deſired. D H is the pipe of communication between the cock and the receiver. E is the pipe that communicates between the cock and the valve, on the upper plate of the barrel. F is the upper plate of the pump, which contains the collar of leathers *d*, and V the valve, which is covered by the piece *f*. G I is the ſiphon gauge, which ſcrews on and off, and is adapted to common purpoſes. It conſiſts of a glaſs tube hermetically ſealed at *c*, and furniſhed with quickſilver in each leg; which, before the pump begins to work, lies level in the line *a b*; the ſpace *b c* being filled with air of the common denſity. When the pump exhauſts, the air in *b c* expands, and the quickſilver in the oppoſite leg riſes, till it becomes a counter-balance to it. Its uſe is ſhewn upon the ſcale I *e*, by which the expanſion of the air in the receiver may be nearly judged of. When the pump condenſes, the quickſilver riſes in the other leg, and the degree may be nearly judged of by the contraction of the air in *b c*: marks being placed at $\frac{1}{2}$ and $\frac{1}{3}$ of the length of *b c* from *c*, which ſhews when the receiver contains double or treble its common quantity. K L is a ſcrew frame to hold down the receiver, in condenſing experiments, which takes off at pleaſure; and is ſufficient to hold down a receiver, the diameter of whoſe baſe is ſeven inches, when charged with a treble atmoſphere; in which caſe it acts with a force of about 800 pounds againſt the ſcrew-frame. M is a ſcrew, that faſtens a bolt, which ſlides up and down in that leg, by means whereof the machine is made to ſtand faſt on uneven ground.

" Fig. 2. is a perpendicular ſection of the barrel and cock, &c. where A B repreſents the barrel. C D the rod of the piſton, which paſſes through M N the plate, which cloſes the top of the barrel. K is the collar of leathers, through which the piſton-rod paſſes. When the piſton is at the bottom of the cylinder, the upper part of K is covered by the cap at D, to keep out duſt, &c. L is the valve on the upper plate which is covered by the piece O, P, which is connected with the pipe Q, R, which makes the communication between the valve and cock. C, E, is the piſton; and E, F, F, is the piſton valve. I, I, are two little holes to let the air paſs from the piſton valve into the upper part of the barrel. G, G, K, is the principal valve at the bottom of the cylinder. H, H, is a piece of metal, into which the valve G, G, K, is ſcrewed, and cloſes the bottom of the cylinder; out of which alſo is compoſed S, S, the cock, and K, T, T, the ducts from the cock to the bottom of the barrel. W, W, is the key of the cock. X, the ſtem; and V, V, the handle.

" Fig. 5. is an horizontal ſection of the cock, through the middle of the duct T, T. A, B, repreſents the bigneſs of the circular plate that cloſes the bottom of the barrel. C, D, repreſents the bigneſs of the inſide of the barrel. E, F, G, is the body of the cock; the outward ſhell being pierced with three holes at equal diſtances, and correſponding to the three ducts, H, H, I, I, K, K, whereof H H is the duct that goes to the bottom of the barrel. I I is the duct that communicates with the top of the barrel; and K K is the duct that paſſes from the cock to the receiver. L, M, N, is the key, or ſolid part of the cock, moveable round in the ſhell E F G. When the canal L M anſwers to the ducts H H and K K, the pump exhauſts, and the air is diſcharged by the perforation N. But, the key L, M, N, being turned till the canal L M anſwers to I I and K K, the perforation N will then anſwer to H H; and, in this caſe, the pump condenſes. Laſtly, when N anſwers to K K, the air is then let in or diſcharged from the receiver, as the circumſtance requires.

" Fig. 3. is the plan of the principal valve. A, B, C, D, repreſents the bladder faſtened in four places, and ſtretched over the ſeven holes I, K, formed into an hexagonal grating, which I ſhall call the honey-comb. E, F, G, H, ſhews where the metal is a little protuberant, to hinder the piſton from ſtriking againſt the bladder.

" Fig. 4 repreſents the new gauge, which I call the pear gauge. It is open at A; B, C, is the graduated tube, which is hermetically cloſed at C, and is ſuſpended by the piece of braſs D, E, that is hollowed into a cylinder, and claſps the tube."

Theory of the AIR-PUMP. The operations of this machine are accounted for by the elaſticity of the air: for, when the piſton is thruſt down to the bottom of its barrel, and then raiſed up, it is evident that the air, which before was contained in the receiver, will now expand itſelf, and part of it will enter into the pump barrel: ſo that the air in the receiver and barrel will have the ſame denſity; but this denſity is to the former as the capacity of the receiver and barrel in one ſum, is to the capacity of the receiver alone; it being well known that the denſity of the air (in the ſame region) is inverſely as the ſpace occupied. (See DENSITY.) Wherefore, putting *d* for the denſity of common air, *m* for the capacity of the receiver, *n* for that of the pump barrel, we ſhall have $m+n:m::d:\frac{dm}{m+n}$, the denſity of the air in the receiver after the firſt ſtroke of the piſton; this being obtained it will be $m+n:m::\frac{md}{m+n}$ (the laſt found denſity) : $\frac{m^2 d}{\overline{m+n}^2}$ the denſity of the air in the receiver after the ſecond ſtroke of the piſton; proceed in this manner for any number of ſtrokes, and if s repreſent that number, the denſity of the remaining air in the receiver at the end of s ſtrokes of the piſton, will be expreſſed by $\frac{d\,m^s}{\overline{m+n}^{\,s}}$, that is, in words, The denſity of the natural air in the receiver is to its denſity after any number of ſtrokes of the piſton, as the capacity of the receiver, and that of the barrel in one ſum, raiſed to a power whoſe index is the number of ſtrokes, is to the like power of the capacity of the receiver alone; which is the theorem given by M. Varignon, in the *Memoires de Mathemat. & Phyſ.* for Dec. 1703. If the above expreſſion for the denſity be put equal to r, we ſhall have $\frac{m^s}{\overline{m+n}^{\,s}} = \frac{r}{d}$, conſequently, by the nature of logarithms, there will ariſe $s \times \log.\overline{m+n} - s \times \log. m = \log. d - \log. r$, which gives the following theorem for finding the ratio of the denſity of the air in its natural ſtate, to that of the air in the receiver, after any number of ſtrokes of the piſton.

Subtract the logarithm of the capacity of the receiver from that of the ſum of the capacity of the receiver and the barrel, then the remainder being multiplied by the number of ſtrokes of the piſton, the product will be a logarithm, whoſe natural number, compared with unity, will ſhew the ratio required.

Thus, if the capacity of the receiver be 460, that of the barrel 580, and the number of ſtrokes of the piſton 6, the primitive air will be found to the remaining air in the ratio of 133½ to 1; that is, the remaining air in the receiver, after 6 ſtrokes of the piſton, is above 133 times more rarefied than in its natural ſtate.

If the capacity of the receiver and the barrel were given, and it were required to find the number of ſtrokes of the piſton neceſſary to rareſy the air to a certain degree, then by the above equation we have $s = \frac{\log. d. - \log. r.}{\log. \overline{m. + n.} - \log. m.}$, that is, in words, Subtract the logarithm of the remaining air from the logarithm of the primitive air; and the logarithm of the capacity of the receiver from that of the aggregate of the capacity of the receiver and barrel; then, dividing the former difference by the latter, the quotient is the number of ſtrokes required.

Thus, if the capacity of the barrel be ſuppoſed 580; that of the receiver 460; and the ratio of the primitive air to the remaining air, as 1335 to 10, the number of ſtrokes required will be found to be 6.

Air-Shafts, among miners, are holes made from the open air to meet the adits, and ſupply them with freſh air.

Theſe air-ſhafts, when the adits are thirty or forty fathoms in length, become abſolutely neceſſary, in order to let in freſh air, and at the ſame time give vent to the damps and noxious vapours.

Air-Threads, in natural hiſtory, a name given to the long filaments, ſo frequently ſeen in autumn floating about in the air.

Theſe threads are the work of ſpiders, eſpecially of that ſpecies called the long-legged field-ſpider; which, having mounted to the ſummit of a buſh or tree, darts from its tail ſeveral of theſe threads, till one is produced capable of ſupporting the creature in the air; on this it mounts in queſt of prey, and frequently riſes to a very conſiderable height.

Nor does the ſpider that has thus raiſed itſelf deſcend always by the ſame thread; it often winds that up, and darts out another, more or leſs long, as the creature intends a higher or lower flight.

Air-Vessels, in plants, are certain veſſels or ducts for imbibing or conveying air to the ſeveral parts of the plant. See **Air**.

AIRIANI, in eccleſiaſtical hiſtory, a branch of the Arians, who beſides the common tenets of that ſect, denied the conſtantiability of the Holy Ghoſt with the Father and Son.

AIRING, in horſemanſhip, implies the exerciſing a horſe in the open air, a practice that cannot be too much commended.

AIRY, or **Aery**, among ſportſmen, implies the neſt of a hawk or eagle.

Airy *Triplicity*, among aſtrologers, denotes the three ſigns Gemini, Libra, and Aquarius.

AISIAMENTA, in law, the ſame with eaſement. See the article **Easement**.

AJUGA, in botany, a name uſed by Linnæus for a genus of plants, called by Tourneſort bugula. See **Bugula**.

AIUS LOCUTIUS, the name of a deity to whom the Romans erected an altar.

The words are Latin, and ſignify, "A ſpeaking "voice."

The following accident gave occaſion to the Romans erecting an altar to the Aius Locutius. One M. Ceditius, a plebeian, acquainted the tribunes, that, in walking the ſtreets by night, he had heard a voice over the temple of Veſta, giving the Romans notice that the Gauls were coming againſt them. This intimation was however neglected; but after the truth was confirmed by the event, Camillus acknowledged this voice to be a new deity, and erected an altar to it under the name of the Aius Locutius.

AJUTAGE, or **Ajutage**, in hydraulics, a ſmall pipe fitted to the aperture of a jet d'eau, or fountain.

Experiments have ſhewn, that a reſervoir of 12 feet height above the orifice of an ajutage of three lines diameter, delivers 14 Paris pints of water in a minute. This may ſerve as a fundamental rule for fountains, aſſiſted by the following principles.

When the height of the reſervoirs is the ſame, and the orifices of the ajutages different, the expence of water is proportional to the ſquares of the diameters of the ajutages, whence the expence of water, through different ajutages, is thus computed. If 9, the ſquare of 3, gives, by experiment, 14 pints, what will an ajutage of 5 or 6 lines give? The anſwer is 39 pints for 5, and 56 pints for 6. Whence M. Mariotte has computed the following table.

	Feet	Pints
Ajutage	1	1 ½
———	2	6 ⅔
———	3	14
———	4	25
———	5	39
———	6	56
———	7	76 ¼
———	8	110 ⅔
———	9	126

Here the heights of the reſervoirs are ſuppoſed equal; but if this condition ceaſes, the conſequence varies. Greater heights give more than ſmaller ones, and the exceſs of the expence is in the ſubduplicate ratio, or as the ſquare roots, of the heights.

The following is another table of M. Mariotte, which ſhews the expence of water for different heights, and the ſame ajutage.

	Feet	Pints
Height	6	10
———	8	11 ½
———	9	12 ⅙
———	10	12 ⅚
———	12	14
———	15	15 ⅔
———	18	17
———	20	18 ½
———	25	20 1/16
———	30	22 1/16
———	35	24
———	40	34 ⅛
———	45	27 ⅙
———	48	28

Obſerve, that in both tables the fractions of fractions are neglected, as inſenſible quantities; and the expences of water are calculated for one minute of time. Moreover, if the expence of two reſervoirs, of unequal heights, and different ajutages, be required, proceed by the following rule. The expence of water of two reſervoirs, whoſe heights are different and alſo their ajutages, are in the compound ratio of the ſquares of the diameters of the ajutages, and of the ſubduplicate ratio of the heights.

Water ſpouting upwards, through an ajutage, would aſcend to the ſame height as that of its upper ſurface in the reſervoir, were it not for the reſiſtance of the air, the friction at the ſides of the ajutage, and ſome little impediments of the motion of the water in itſelf, on account of all which, this height of the riſe is always defective.

It is found, by experience, that if the direction of the ajutage be a ſmall matter inclined, the water will riſe higher than if it be truly upright; and that a poliſhed round hole, in a thin plate of metal, at the top of the pipe, by way of ajutage, will ſuffer the water to ſpout higher than when it is cylindrical or conical.

Experience alſo ſhews, that the bigneſs of the pipe of the ajutage ſhould be enlarged at and near the ſurface of the water in the reſervoir, and that ſuch pipe ſhould be much larger than the ajutage; alſo, that there is a certain length among the ſeveral diameters of the ajutages, which will give the ſpout the greateſt height poſſible, and which muſt not exceed an inch and a quarter. Likewiſe the height of the ſpout muſt have its limits, an hundred feet being almoſt as much as it will bear.

Let A B (plate VII. *fig.* 3.) be the height of a ciſtern filled with water, which biſect in C; about the center C with the radius C B, deſcribe the ſemicircle A D B: now, if E be an ajutage in the ſide of the ciſtern, and E D be drawn perpendicular to A B, alſo B G, upon the horizontal plane, and taken equal to 2 E D, the water will run out from E to G, which may be thus proved. It is well known that E H F, the curve which the water iſſuing from the aperture at E deſcribes in its fall, is the common parabola; alſo that the velocity of the effluent water at E muſt, in order that it may deſcribe the ſaid parabola, be equal to that which a heavy body would acquire by falling through a height equal to $\frac{1}{4}$ of its parameter. See PROJECTILE.

But ſince this velocity is acquired by the deſcent through A E, it follows that A E muſt be $\frac{1}{4}$ of the parameter, or, which is the ſame thing, $AE = \frac{BG^2}{4BE}$. By the foregoing conſtruction we have $CB^2 - CE^2 = ED^2$, $CB - CE = AE$, and $BG = 2ED$; conſequently $BG^2 = 4ED^2$; therefore $AE = \frac{ED^2}{BE}$; that is, $CB - CE = \frac{ED^2}{BE}$; for ED^2 put its equal $CB^2 - CE^2$, we have $CB - CE = \frac{\overline{CB^2 - CE^2}|}{BE}$: divide each ſide by $CB - CE$, there will ariſe $1 = \frac{CB + CE}{BE}$, or $BE = CB + CE$, which being manifeſt, by the figure, proves above the conſtruction to be juſt.

Hence it follows, that a liquid ſpouting from a hole in the center C, will go to the greateſt diſtance poſſible; and that all apertures equally above and below the center C, have exactly the ſame amplitudes upon the horizontal plane. Let the areas of the baſes of two unequal cylindrical veſſels of water, be called B and b, their heights H and h, D and d the areas of the holes or ajutages through which they are evacuated, T and t the times of running reſpectively; then the quantities run out from thoſe cylinders (conſtantly kept full), in the times T and t, will be in the proportion of $T \times \sqrt{H} \times D$ to $t \times \sqrt{h} \times d$. Wherefore, expounding thoſe quantities by Q and q, we ſhall have $T \times \sqrt{H} \times D : t \times \sqrt{h} \times d :: Q : q$. If $Q : q :: B + H : b \times h$; then $T \times \sqrt{H} \times D : t \times \sqrt{h} \times d :: B \times H : b \times h$, and by multiplying extremes and means, we get $T \times \sqrt{H} \times D \times b \times h = t \times \sqrt{h} \times d \times B \times H$, whence $T \times D \times b \times \sqrt{h} = t \times d \times B \times \sqrt{H}$. From theſe equations may be deduced the following corollaries.

1. The ſquares of the quantities flowing out from the ſame ajutage, in equal times, are in the ratio of the heights of the liquid above the aperture: for when $T = t$, and $D = d$, $Q^2 : q^2 :: H : h$.

2. The times in which cylindrical veſſels of the ſame diameter and height are emptied, the liquid flowing from unequal apertures, are in the inverſe ratio of the areas of thoſe apertures. For $T : t :: d : D$, when $H = h$ and $B = b$.

3. Cylindrical veſſels of unequal baſes, but of equal heights, are emptied through equal apertures in times that are in the ratio of their baſes. For $T : t :: B : b$, when $H = h$ and $D = d$.

4. The times in which any cylindrical veſſels are evacuated, are in a ratio compounded of the baſes, the inverſe ratio of the apertures, and direct ratio of the ſquare roots of the heights. For $T : t :: B \times d \times \sqrt{H} : b \times D \times \sqrt{h}$.

If the ſide of a cylindrical veſſel, beginning from the baſe, be divided into lengths, which are as 1, 4, 9, 16, &c. viz. the ſquares of the natural numbers 1, 2, 3, 4, &c. the ſurface of the water (running out through a hole or aperture at the bottom) will deſcend from each of thoſe diviſions to the next, in the ſame time.

In the above inveſtigations, we always ſuppoſe the velocity of the effluent water to remain conſtant during the evacuation; and therefore, when we ſpeak of the time of emptying a cylindrical veſſel, we only mean that time in which (the veſſel being kept conſtantly full) a quantity of the liquid, equal in magnitude to the capacity of the veſſel, will flow through the ajutage, or aperture, in the ſide of the perpendicular cylinder.

AJUTANT, in military affairs. See the article ADJUTANT.

ALA, in botany, is uſed in various ſenſes; ſometimes it denotes the hollow between the ſtalk of a plant and its leaves; and ſometimes it is applied to the two ſide petals of the papilionaceous flowers; the upper petal being called the *vexillum*, and the lower the *carina*: others uſe it for the ſlender membranaceous parts of ſome ſeeds; and others again for the membranaceous expanſions, found on the ſtems of plants, thence called alated ſtalks.

The word is Latin, and properly ſignifies a wing.

ALÆ, in anatomy, is ſometimes uſed for the lobes of the liver, the nymphæ of the female pudendum, the two cartilages which form the noſtril, the arm-pits, &c.

ALÆ, among the ancient Romans, ſignified the two wings, or extreme parts of the army, drawn up in order of battle.

ALABASTER, *Alabaſtrites*, in natural hiſtory, the name of a genus of foſſils, nearly allied to that of marble. It is an elegant ſtone of great brightneſs, and will receive a fine poliſh, but is brittle.

Naturaliſts enumerate ſeveral ſpecies of alabaſter: as, the ſnow-white ſhining alabaſter, or that called the lygdine by the ancients. Boet informs us, that this ſtone is extremely white, and found in Taurus in pieces only large enough to make diſhes and the like; but it was formerly brought from Arabia. It is not very compact, but heavy, and conſiſts of a multitude of broad, flat, large particles, which are very bright, and perfectly white. It cuts very freely, and is capable of a fine poliſh. There are very large ſtrata of it in Arabia, Egypt, and many parts of Italy; but it is ſeldom brought over to England.

Whitiſh yellow alabaſter is of a ſoft conſiſtence, and called by Boet, the phengites of Pliny, who affirms it was found in Cappadocia, and that Nero built the temple of Fortune with whitiſh yellow alabaſter. This temple ſhone on the inſide, like paper ſmeared with oil, and not tranſparent. He farther adds, that this ſpecies of alabaſter differs in nothing from common marble but in hardneſs, and in its ſhining when poliſhed. It is of a looſe open texture, conſiderably heavy, and nearly of the colour of honey; but the colour is more deep in ſome places than others. It conſiſts of irregular pieces lying in tables one over another, though with regularity, and altogether compoſe a remarkable bright and very brittle maſs. Beſides the places above-mentioned, it has been found in Germany, France, and Derbyſhire.

Yellow and reddiſh variegated alabaſter is the common alabaſter of the ancients. It is ſo ſoft that it may be cut with a knife; and has the ſame name in all languages. It is remarkably bright, glittering, and almoſt tranſparent;

and its texture very looſe and open, though it is moderately heavy. The ground is of a clear pale yellow, between that of honey and amber, and has the ſame texture as the phengites; but it is beautifully variegated with crooked undulated veins, ſome of which are broad, and others narrow; ſome of a pale red, others whitiſh, and others again of a very agreeable pale brown. It will bear a very fine poliſh, and conſiſts of large angular ſparry concretions. It was formerly found only in Egypt, but is now met with in many parts of England. *Brookes's Natural Hiſtory.*

ALABASTRÆ, in botany, was a name given by the ancients to the cup of flowers, particularly to the roſe before it is expanded.

A-LA-MI-RE, among muſicians, is the name of a note in the modern ſcale. See GAMUT.

ALAMODE, in commerce, the name of a very thin, gloſſy, black ſilk, chiefly uſed for women's hoods and men's mourning ſcarfs.

ALARES *Muſculi*, in anatomy, the Latin name of the muſcles generally called pterygoidei. See the article PTERYGOIDEUS.

ALARM, in military affairs, implies either the apprehenſion of being ſuddenly attacked, or the notice of ſuch an attack, ſignified by the firing of a cannon, muſket, or the like.

Falſe alarms are frequently made uſe of to harraſs the enemy, by keeping them continually under arms.

ALARM-BELL, the bell rung upon any ſudden emergency, as a fire, mutiny, approach of an enemy, or the like.

ALARM-POST, the place appointed for drawing up a regiment in caſe of an alarm.

ALARM, the name of a kind of clock, contrived for waking people at a certain hour, by making an uncommon noiſe, &c.

ALATED *Leaves*, in botany, are thoſe compoſed of ſeveral pinnated ones. See PINNATED.

ALATERNUS, in botany, the name of a diſtinct genus of plants, according to Tournefort's ſyſtem; but comprehended by Linnæus among the rhamnuſes. Its flower conſiſts of one funnel-ſhaped leaf, divided into four deep ſegments; and the fruit is a berry, containing, for the moſt part, three ſeeds, globoſe on one ſide, and angular on the other.

ALAUDA, the lark. See the article LARK.

ALB, or ALBE, in the Roman church, a veſtment of white linnen, hanging down to the feet, and anſwering to the ſurplice of our clergy. It was cuſtomary in the ancient church for thoſe newly baptized to wear the alb, or white veſtment; and hence the Sunday after Eaſter was called *Dominica in Albis*, on account of the albs worn by thoſe who had been baptized on Eaſter-day.

ALB is alſo the name of a Turkiſh coin, otherwiſe called aſper. See the article ASPER.

ALBANENSES, Chriſtian heretics in the reign of the emperor Conſtantine VI. and the pontificate of Leo III. about the year 796. Their principal errors were as follow: they held, with the Gnoſtics and Manichæans, two principles, the one of good, the other of evil; and they aſcribed the Old Teſtament to the evil god, and the New Teſtament to the good god. They held, with Pythagoras, a tranſmigration of ſouls. They denied the divinity, and even humanity of Jeſus Chriſt, aſſerting that he was not truly man, that he did not really eat, nor ſuffer on the croſs, nor die, nor riſe again, nor aſcend into heaven. They denied a reſurrection of the body, and affirmed, that the general judgment was paſt. They held, that there had never been a good man in the world before Jeſus Chriſt, and therefore that neither Adam nor Moſes were from God. They denied that there was any virtue or efficacy in baptiſm. They ſaid likewiſe, that the bad life of prelates hurt the ſacraments; that no bad man could be a biſhop; that the church ought to have every thing in common, and could not excommunicate any perſon, or make any conſtitutions. They believed, that hell-torments were no other than the evils we feel and ſuffer in this life. They rejected the ſacrament of the altar, and extreme unction; they did not admit original ſin; for which reaſon they never adminiſtered baptiſm to infants. They denied free-will. They held the eternity of the world. They diſallowed of marriage. They ſaid, that uſury was not prohibited, and that no one was obliged to reſtitution. They held, that a man gives the holy ſpirit of himſelf, and that it is unlawful for a Chriſtian to take an oath.

ALBANI, in antiquity, a college of the Salii, or the prieſts of Mars, ſo called from mount Albanus, the place of their reſidence.

ALBATI, a ſort of Chriſtian hermits in the year 1399, in the time of pope Boniface IX. They were ſo called from the white linen which they wore. They came down from the Alps into ſeveral provinces of Italy, under the conduct of a prieſt cloathed in white, and holding a crucifix in his hand. The followers of this prieſt, whoſe great zeal made him looked upon as a ſaint, multiplied ſo faſt, that it alarmed the pope, who ſending ſoldiers, apprehended and put him to death; upon which his followers immediately diſperſed. Theſe monks profeſſed ſorrow and weeping for the ſins and calamities of the times: they eat together in the highways, and ſlept promiſcuouſly.

ALBE, a ſmall piece of money, current in Germany, worth about three half-pence.

ALBERTUS, a gold coin, worth about fourteen ſhillings; it was coined during the adminiſtration of Albertus, archduke of Auſtria.

ALBIGENSES, a ſect or party of reformers, about Toulouſe and Albigeois, in Languedoc, who ſprung up in the 12th century, and diſtinguiſhed themſelves by their oppoſition to the diſcipline and ceremonies of the church of Rome. They were likewiſe called Waldenſes.

Their riſe was occaſioned by an accident. It happened at Lyons, in a great concourſe of people, that one of them fell down on a ſudden dead, at which all that were preſent were extremely terrified; in particular one Peter Waldius, who immediately ſold his goods, and divided them amongſt the poor. Great multitudes preſently flocked about him, and he, being ſomething of a ſcholar, read and explained to them the New Teſtament in their own tongue, and inſtructed them in the true principles of the Chriſtian religion. The number of his diſciples increaſing greatly, this ſect ſpread, and prevailed every-where.

At length the Albigenſes grew ſo formidable, that the Catholics agreed upon a holy league or cruſade againſt them. They were at firſt ſupported by Raimond, count of Toulouſe. Pope Innocent III. deſirous to put a ſtop to their progreſs, ſent a legate into their country; but this failing, he ſtirred up Philip Auguſtus, king of France, and the other princes and great men of the kingdom, to make war upon them; upon which the count of Toulouſe, who had ſided with them, made his ſubmiſſion to the pope, and went over to the Catholics: but ſoon after, finding himſelf plundered by the cruſaders, he declared war againſt them, and was joined by the king of Arragon. His army was defeated at the ſiege of Muret, where he himſelf was killed, and the defeat followed by the ſurrender of the city of Toulouſe, and the conqueſt of the greateſt part of Languedoc and Provence. His ſon Raimond ſucceeded him, who agreed with the king and the pope to ſet up the inquiſition in his eſtates, and to extirpate the Albigenſes. In an aſſembly held at Milan, the archbiſhop of Toulouſe drew up articles, agreeable to which the count made a moſt ample declaration againſt them, which he publiſhed at Toulouſe, in 1253. This laſt blow completed the ruin of the Albigenſes.

The errors with which they were charged are theſe: 1. That they acknowledged two principles, the one good, the other evil; the firſt, creator of things inviſible and ſpiritual; the ſecond, creator of bodies, and guardian of the Old Teſtament. 2. That they admitted likewiſe two Chriſts; the one wicked, who was he that had appeared on earth; the other good, who was not yet come. 3. That they denied the reſurrection of the body, and believed that the ſouls of men are demons ſent into their bodies for the puniſhment of their ſins. 4. That they condemned all the ſacraments of the church, and believed marriage to be unlawful.—As to their manner of life, there were ſaid to be two ſorts of people among them, the Perfect, and the Believers. The Perfect boaſted of their living in continence, of eating neither fleſh, eggs, nor cheeſe. The Believers lived like other men, and were even looſe in their morals; but they were perſuaded they ſhould be ſaved by the faith of the Perfect, and that none were damned who received impoſition of hands from them.

But, perhaps, this charge againſt them was only calumny: for Æneas Sylvius, giving an account of them, ſays, that this ſect had a great appearance of piety; that they lived juſtly before men, and believed all the articles of the creed; and that they only blaſphemed the church of Rome and the clergy. *Hinc illæ lachrymæ:* it was their oppoſing the received doctrines of that church, and the corrupt manners of the eccleſiaſtics, that drew upon them the ſtorm which ended in their deſtruction.

ALBION, the ancient name of Britain. See the article BRITAIN.

ALBITROSSE, the name of a bird, very common in ſeveral parts of the Weſt-Indies; but not reduced to any certain genus.

ALBORAK, among Mahometan writers, the beaſt on which Mahomet rode in his journey to heaven.

ALBUGINEA *Tunica*, in anatomy, the third or innermoſt coat of the teſticles, ſo called from its white colour.

ALBUGINEA is alſo a name given by ſome anatomiſts to one of the coats of the eye, called alſo adnata. See the article EYE.

ALBUGINEUS, an appellation given by ſome to the aqueous humour of the eye. See EYE.

ALBUGO, among phyſicians, denotes a diſtemper of the eye, cauſed by a white, denſe, and opaque ſpot growing on the tunica cornea.

The word is formed from the Latin *albus*, white.

This is a troubleſome diſeaſe, which is more or leſs offenſive to the ſight, according to the greater or leſs portion of the tranſparent part of the cornea affected by it: for ſometimes it fixes on the exterior ſurface only of this membrane, ſometimes on the interior, and ſometimes it runs more or leſs deep into it.

It is moſt commonly the conſequence of inflammations, by the extravaſation of humours between the membranes of this tunicle, and particularly in the ſmall-pox, by the ſuppuration of puſtules upon this part.

I have, ſays the learned Dr. Mead, made uſe of two methods of cure for this diſorder of the ſight; the one in the outward ſort, the other in the inward. In the former caſe I ordered the following powder.

Take of common glaſs any quantity; pound it in a mortar, into a very fine powder; then add an equal quantity of white ſugar candy, and levigate the mixture on a marble with great labour, till it becomes quite impalpable.

A little of this powder, put into the eye with a quill every day, gradually abſterges and wears off the ſpot by its inciding quality. The other method above-mentioned of removing this ſpeck is, to order a dexterous ſurgeon to pare it cautiouſly every day with a knife; for this tunicle is compoſed of ſeveral lamellæ one over another, and has thickneſs enough to bear paring off ſome of its parts. I have ſeen ſeveral inſtances of cures by the eye-powder, but the paring of the coat has not ſucceeded with me above once or twice. However, it is better to try a doubtful remedy than none. *Mead's Monita & Præcepta.*

The French ſurgeons ſcarify the eye for this diſeaſe with the briſtles or beards of rye-graſs; that is, about twenty or twenty-five of them tied together, like a little bruſh or pencil; and with this they bruſh the eyes ſometimes till a little blood comes, repeating the ſame every other or third day, four or five times, or more. After the operation, they waſh the eye very often with warm water, and at night apply the pulp of a roaſted apple.

ALBUM, in antiquity, a kind of table or regiſter, wherein the names of certain magiſtrates, public tranſactions, &c. were entered.

ALBUM *Græcum*, in the old materia medica, the white dung of dogs, ſaid to be good for inflammations of the throat; but little regarded at preſent.

ALBUMEN, a term uſed by medical writers for the white of an egg.

It is uſed in collyriums, on account of its cooling and agglutinating quality: it is alſo often an ingredient in ointments for burns.

ALBURN, the Engliſh name for a ſort of compound colour, formed by mixing red and white.

ALCAICS, in ancient poetry, a denomination given to ſeveral kinds of verſe, from Alcæus their inventor.

The firſt kind conſiſts of five feet, viz. a ſpondee, or iambic; an iambic; a long ſyllable; a dactyle; another dactyle: ſuch is the following verſe of Horace,

Omnes | eo | dem cogimur, | omnium
Verſa | tur ur | nâ | ſerius | ocyus |
Sors exitura.

The ſecond kind conſiſts of two dactyles and two trochees: as,

Exili | um impoſi | tura | cymbæ.

Beſides theſe two, which are called dactylic Alcaïcs, there is another ſtiled ſimply Alcaïc; conſiſting of an epitrite; a coriambus; another coriambus; and a bacchius; the following is of this ſpecies,

Cur timet fla | vum Tiberim tangere, cur | olivum?

ALCAIC *Ode*, a kind of manly ode compoſed of ſeveral ſtrophes, each conſiſting of four verſes; the two firſt of which are always Alcaïcs of the firſt kind; the third verſe is a dimeter hypercatalectic, or conſiſting of four feet and a long ſyllable; and the fourth verſe is an Alcaïc of the ſecond kind. The following ſtrophe is of this ſpecies, which Horace calls *minaces Alcæi camenæ.*

Non poſſidentem multa vocaveris
Rectè beatum: rectiùs occupat
Nomen beati, qui deorum
Muneribus ſapienter uti, &c. Hor.

ALCAID, ALCAYDE, or ALCALDE, among the Spaniards and Portugueſe, is a magiſtrate, or officer of juſtice, anſwering nearly to our juſtice of peace. The alcaid is properly a Mooriſh officer, where he is inveſted with ſupreme juriſdiction, both in civil and criminal caſes.

ALCALI, or ALKALI, a general appellation given by phyſicians and chemiſts to all ſubſtances, which, on being mixed with acids, excite an efferveſcence.

The word originally ſignified the ſalt extracted from the aſhes of *kali*, or glaſs wort: but was afterwards applied to all ſalts that efferveſced with acids.

Alcalies are generally divided into two kinds, and diſtinguiſhed by the epithets of *fixed* and *volatile*.

Fixed ALKALIES are diſtinguiſhed from ſaline ſubſtances not alkaline, by their efferveſcing with all acids, forming with them neutral ſalts, precipitating ſolutions made in acids, and changing ſyrup of violets green.

They are diſtinguiſhed from volatile alcalies by their fixity and fuſibility in the fire, by their deliquiating in the air, and never aſſuming a cryſtalline form, changing ſolution of mercury ſublimate not white, but of an orange yellow, producing no blue colour with copper or its ſolutions, raiſing no viſible cloud when placed near an unſtopt bottle of ſpirit of nitre, occaſioning no coldneſs but rather heat on being diſſolved in water. Pure fixed alcalies, diſſolved in water, mingle with a ſolution of any other pure alcali, without the leaſt precipitation, turbidneſs, or ſenſible change.

Fixed alcalies diſſolve ſulphur, oils, fats, and reſinous bodies. By quick-lime their activity is increaſed, and in this ſtate they diſſolve ſome metallic ſubſtances, as calces or filings of lead, fine filings of copper, copper precipitated from vitriol, the copper in verdigris, tin, and regulus of antimony: this laſt they corrode into a calx, which, by force of fire, may be melted into an amber coloured glaſs. There are two ways of obtaining ſolutions of iron in theſe ſalts: one, by dropping a ſolution of the metal made in aqua-fortis into a ſtrong alcaline ley, the acid will be abſorbed and neutralized by a part of the alcali, and the iron remains diſſolved by the reſt: the other is, by deflagrating iron filings with nitre, the acid of the nitre will be diſſipated in the deflagration, and great part of the iron will diſſolve in water along with the remaining alcali. Theſe ſalts, combined with ſulphur, diſſolve almoſt all the metals and ſemi-metals, gold itſelf not excepted. When made fluid by a ſtrong fire, they diſſolve flint, ſand, and other earthy bodies, and on cooling concrete with them into a maſs, which proves diſſoluble in water, or an indiſſoluble glaſs, according as the proportion of the earth is large or ſmall. Added to phlegmatic ſpirits, either of the inflammable or volatile urinous kind, they imbibe the redundant phlegm, and thus render the ſpirit more concentrated. In pure vinous ſpirits they do not diſſolve, or only in very ſmall quantity, ſufficient however to give a ſenſible acrimony or alkaline impregnation to the ſpirit. If both the ſpirit and the ſalt are pure, the liquor receives no colour; but if any oily or reſinous matter be previouſly diſſolved in the ſpirit, or if the ſalt be impregnated, though ſlightly, with inflammable matter of any kind, a conſiderably deep tincture will be produced. Fixed alkalies, in general, heighten the colour of vegetable and animal tinctures, whether drawn with water or with ſpirit; but they commonly vary the taſte, and often debaſe the ſmell of the preparation.

They form, with acids, different neutral ſalts, according to the nature of the acid employed; with the vitriolic, a bitteriſh ſalt, very difficult of ſolution in water, and not fuſible in the fire, commonly called vitriolated tartar, the alkaline ſalt made from tartar being that which has chiefly been employed for theſe purpoſes; with the nitrous acid, they form a perfect nitre; with the marine, a ſalt greatly reſembling ſea-ſalt, being in ſome reſpects different from the common vegetable alkalies. They readily cryſtallize with any of the mineral acids, and with tartar; with which laſt they compoſe a neutral ſalt, much eaſier of ſolution than the tartar itſelf, and hence called ſoluble tartar. They do not eaſily cryſtallize with the acid of vinegar or lemon juice; theſe mixtures, if by careful management reduced to a cryſtalline form, ſoon deliquiate again in the air.

There are different ways, beſides immediate mixture, of obtaining combinations of fixed alkalies with acids, depending upon their great affinities with one another. Thus, when any metallic body is diſſolved in an acid, the addition of an alkaline ſalt precipitates the metal: if the remaining liquor be filtered and evaporated, it leaves a neutral ſalt, compoſed ſolely of the acid and the alkali. Some of the metals ſuffer a notable alteration in this proceſs: thus the calx of iron, precipitated from the vitriolic acid in making vitriolated tartar, is ſcarce at all revivable into malleable iron again. When acids are combined with volatile alkalies into ammoniacal ſalts, and this compound mixed with a fixed alkali; on expoſing the mixture to the action of a moderate fire, in a retort or other convenient veſſel, the volatile alkali ariſes, and the acid remains combined with the fixed: if it was not for the intervention of the fixed alkali, it would ſublime in conjunction with the volatile. In like manner, when ſulphur, or oils, or reſins, are diſſolved by a fixed alkali, the addition of any acid will ſeparate the ſubſtance before diſſolved, the acid and the alkali uniting together; and even when both of them are previouſly ſaturated, the alkali, for inſtance, with ſulphur, and the acid with metal, on mixing the two ſolutions together, both the ſulphur and the metal fall, leaving only the alkali and the acid combined in the liquor. When the alkali is previouſly combined with one acid, the addition of a more powerful acid will break the union, and diſengage the alkali from the firſt acid. On the neutral ſalt, compoſed of fixed alkali and vinegar, pour ſome ſpirit of common ſalt; the acetous acid will inſtantly begin to exhale, and, on applying a moderate heat, will be totally diſſipated, leaving the alkali combined with the marine acid. Add to this combination a due proportion of the nitrous acid, and the marine will be expelled, and a perfect nitre remain. The vitriolic, in like manner, expels the nitrous, and takes poſſeſſion of the alkali in its place: this being the moſt powerful acid, is not to be diſlodged by any other.

When this acid is combined with inflammable matter into ſulphur, it loſes its great affinity to alkalies. If the neutral ſalt, compoſed of the vitriolic acid and fixed alkali, be melted with powdered charcoal, the reſult is a mixture of alkali and ſulphur. On diſſolving this compound in water, the ſlighteſt even of the vegetable acids precipitates the ſulphur, and unites the alkali. *Neumann's Chemiſtry.*

Preparation of fixed ALCALIES.—The moſt commodious method of preparing fixed alkaline ſalts in the large way, ſeems to be that directed by Kunckel in his Art of Glaſs. The aſhes of wood, or the woody parts of vegetables, either burnt on purpoſe or as common fuel, are to be put into a large tub or vat, whoſe bottom is covered with pieces of ſplit wood and ſtraw, to prevent the aſhes from ſtopping up the cock. So much water is to be poured on the aſhes as may totally cover them: after ſtanding for a night, the liquor, impregnated with their ſaline part, is to be let off by the cock at the bottom into another veſſel; and the elixation repeated with freſh water ſo long as the ley has any ſaline taſte. The elixated aſhes may be uſed, like common wood-aſhes, for manure; and the weak leys may be rendered ſtronger, by pouring them, inſtead of plain water, upon a freſh quantity of aſhes. Thus from every parcel of aſhes we obtain a ſtrong ley, with a weaker one to be returned on the next. Where the ley is to be kept in its liquid ſtate, wooden veſſels (according to him) are more commodious than earthen ones, however glazed; theſe laſt being ſooner corroded and penetrated by the acrid liquor.

In procuring a ſolid ſalt, the ley is to be evaporated in an iron pan, fixed in brick-work; freſh ley being continually ſupplied during the evaporation, in a very ſlender ſtream, from a caſk placed on the brick-work, till the quantity of ſalt is as large as can be conveniently dried in the veſſel. This impure brown or blackiſh ſalt is to be calcined, in a furnace built for that uſe, with a red heat juſt not ſtrong enough to melt it, and every now and then turned up and ſtirred for ſix or ſeven hours, or till ſome of the larger pieces, taken out and broke, appear internally white. Thus we obtain an alkali ſufficiently pure for all the buſineſſes in which theſe kinds of ſalts are employed: if, for particular purpoſes, a further purification ſhould be required, it may be diſſolved, inſpiſſated, and calcined afreſh. The rough ſalt loſes, in the firſt calcination, commonly about one tenth of its weight.

Some ſoak in the ley a quantity of ſtraw, bean-ſtalks, or other like ſubſtances, ſufficient to imbibe it; and, by drying and burning theſe, obtain the ſalt of the ley, without the trouble of boiling it down. The earthy matter left by the ſtraw is, in quantity, inconſiderable, and, for many purpoſes, of no injury to the ſalt, particularly for ſoap boiling, bleaching, &c. where the ſalt is diſſolved, and conſequently purified from indiſſoluble earthy admixtures before it is uſed. There is nevertheleſs one great inconvenience in the proceſs; the ſtraw, when loaded with the alkali, being very difficultly made to burn. Vegetable ſubſtances in general, when fully impregnated with fixed alkaline ſalts, never flame; and do not burn at all without a continuance of external heat, inſomuch that ſome have propoſed the impregnating of wood for buildings with ſalts, as an effectual means for preventing its receiving or communicating fire.

The ſtrength of leys, or the quantity of ſalt diſſolved in them, may be eſtimated by the weight of a certain meaſure of them, compared to the weight of an equal meaſure of water; or more commodiouſly, and perhaps as accurately, by means of an hydrometer graduated from actual trials with leys of known ſtrength. *Neumann's Chemiſtry.*

Volatile ALCALIES, are ſalts formed by a new combination of the conſtituting particles of a natural body, by the operation of putrefaction.

Volatile alkalies, from whatever ſubſtance obtained, are all alike, and have the ſame properties; differing only according to their degrees of purity. The volatile alkali, as well as the fixed, conſiſts of a certain quantity of acid, combined with and entangled by a portion of the earth of the mixed body from which it was obtained; and on that account it has many properties like thoſe of a fixed alkali. But there is, moreover, in its compoſition, a conſiderable quantity of a fat or oily matter, of which there is none in a fixed alkali; and, by this means, there is a great difference between them. Thus the volatility of the alkali produced by putrefaction, which is the principal difference between it and the other kind of alkali, whoſe nature it is to be fixed, muſt be attributed to the portion of oil which it contains: for there is a certain method of volatilizing fixed alkalies, by means of a fatty ſubſtance.

Volatile alkalies have a great affinity with acids, unite therewith rapidly and with ebullition, and form with them neutral ſalts, which ſhoot into cryſtals, but differ from one another according to the kind of acid employed in the combination.

The neutral ſalts which have a volatile alkali for their baſis are in general called ammoniacal ſalts. That whoſe acid is the acid of ſea-ſalt, is called ſal ammoniac. As this was the firſt known, it gave name to all the reſt. Great quantities of this ſalt are made in Egypt, and thence brought to us. They ſublime it from the ſoot of cows-dung, which is the fewel of that country, and contains ſea-ſalt, together with a volatile alkali, or at leaſt the materials proper for forming it; and conſequently all the ingredients that enter into the compoſition of ſal ammoniac. See the Memoirs of the Academy of Sciences.

The neutral ſalts formed by combining the acids of nitre and of vitriol with a volatile alkali are called, after their acids, nitrous ſal ammoniac and vitriolic ſal ammoniac: the latter, from the name of its inventor, is called Glauber's ſecret ſal ammoniac.

A volatile alkali, then, has the ſame property as a fixed alkali, with regard to acids; yet they differ in this, that the affinity of the former with acids, is weaker than that of the latter: and hence it follows, that any ſal ammoniac may be decompounded by a fixed alkali, which will lay hold of the acid, and diſcharge the volatile alkali.

A volatile alkali will decompound any neutral ſalt which has not a fixed alkali for its baſis; that is, all ſuch as conſiſt of an acid, combined with an abſorbent earth or a metallic ſubſtance. By joining with the acids, in which they are diſſolved, it diſengages the earths or metallic ſubſtances, takes their place, and in conjunction with their acids forms ammoniac ſalts.

Hence it might be concluded that of all ſubſtances, next to the phlogiſton and the fixed alkalies, volatile alkalies have the greateſt affinity with acids in general: yet there is ſome difficulty in this matter; for abſorbent earths and ſeveral metallic ſubſtances are alſo capable of decompounding ammoniacal ſalts, diſcharging their volatile alkali, and forming new compounds by uniting with their acids. This might induce us to think that theſe ſubſtances have nearly the ſame affinity with acids.

But it is proper to obſerve, that a volatile alkali decompounds ſuch neutral ſalts as have for their baſis either an abſorbent earth or a metallic ſubſtance, without the aid of fire; whereas abſorbent earths or metallic ſubſtances will not decompound an ammoniacal ſalt, unleſs they be aſſiſted by a certain degree of heat.

Now, as all theſe matters are extremely fixed, at leaſt in compariſon with a volatile alkali, they have the advantage of being able to reſiſt the force of fire, and ſo of acting in conjunction therewith; and fire greatly promotes the natural action of ſubſtances upon one another: whereas the volatile alkali in the ammoniacal ſalt, being unable to abide the force of fire, is compelled to deſert its acid; and that ſo much the more quickly, as its affinity therewith is conſiderably weakened by the preſence of an earthy or metallic ſubſtance, both of which have a great affinity with acids.

Theſe conſiderations oblige us to conclude, that volatile alkalies have a ſomewhat greater affinity than abſorbent earths and metallic ſubſtances with acids.

Ammoniacal ſalts, projected upon nitre in fuſion, make it detonate; and the nitrous ſal ammoniac detonates by itſelf, without the addition of any inflammable matter. This ſingular effect evidently demonſtrates the exiſtence of an oily matter in volatile alkalies; for it is certain that nitre will never deflagrate without the concurrence, and even the immediate contact, of ſome combuſtible matter.

This oily ſubſtance is often found combined with volatile alkalies in ſuch a large proportion as to diſguiſe it in ſome meaſure, and render it exceeding foul. The ſalt may be freed from its ſuperfluous oil by repeated ſublimations; and particularly by ſubliming it from abſorbent earths, which readily drink up oils. This is called the rectification of a volatile alkali. The ſalt, which before was of a yellowiſh or dirty colour, by being thus rectified, becomes very white, and acquires an odour more pungent and leſs fetid than it had at firſt; that is, when obtained by one ſingle diſtillation from a putrid ſubſtance.

It is proper to obſerve, that the rectification of a volatile alkali muſt not be carried too far, or repeated too often; for by that means it may be entirely decompoſed at length; and particularly if an abſorbent earth, and eſpecially chalk, be employed for that purpoſe, the ſalt may be converted into an oil, an earth, and water.

Volatile alkalies act upon ſeveral metallic ſubſtances, and particularly on copper; of which they make a moſt beautiful blue ſolution. On this property depends a pretty ſingular effect, which happens ſometimes when we attempt, by means of a volatile alkali, to ſeparate copper from any acid with which it is combined. Inſtead of ſeeing the liquor grow turbid, and the metal fall, both which generally happen when any alkali whatever is mixed with a metallic ſolution, we are ſurpriſed to obſerve the ſolution of copper, upon adding a volatile alkali, retain its limpidity, and let fall no precipitate; or at leaſt, if the liquor does grow turbid, it remains ſo but for a moment, and inſtantly recovers its tranſparency.

This is occaſioned by adding ſuch a quantity of volatile alkali, as is more than ſufficient fully to ſaturate the acid of the ſolution, and conſiderable enough to diſſolve all the copper as faſt as it is ſeparated from the acid. On this account the liquor acquires a deeper blue than it had before; which ariſes from the property which volatile alkalies have of giving this metal, when combined with them, a fuller blue than any other ſolvent can: hence we have a touch ſtone to diſcover copper whereever it is; for let the quantity of this metal, combined with other metals, be ever ſo ſmall, a volatile alkali never fails to diſcover it, by making it appear of a blue colour.

Though a volatile alkali be conſtantly the reſult of putrefaction, yet it muſt not therefore be imagined that none can be produced by any other means; on the contrary, moſt of thoſe ſubſtances which contain the ingredients neceſſary to form it, yield no inconſiderable quantity thereof in diſtillation. Tartar, for example, which by being burnt in an open fire, is converted into a fixed alkali, yields a volatile alkali when it is decompoſed in cloſe veſſels; that is, when it is diſtilled: becauſe, in this latter caſe, the oily part is not diſſipated or burnt, as it is by calcination in a naked fire, but has time to unite with ſome of the earth and acid of the mixed in ſuch a manner, as to form a true volatile alkali.

To prove that on this occaſion, as well as on all others, where unputrified bodies yield a volatile alkali, this ſalt is the product of the fire, we need only obſerve, that, in theſe diſtillations, it never riſes till after ſome part of the phlegm of the acid, and even of the thick oil, is come over; which never is the caſe when it is formed beforehand in the body which is the ſubject of the operation, as it is in thoſe which have undergone putrefaction: for this ſalt, being much lighter and more volatile than thoſe other ſubſtances, riſes of courſe before them in diſtillation.

ALCANNA, in commerce, a powder prepared from the leaves of the Egyptian privet, in which the people of Cairo drive a conſiderable trade. It gives a yellow colour, when ſteeped in common water; and a red one when infuſed in vinegar or alum water. They alſo extract an oil of a very agreeable odour from the berries of the alcanna, and uſe it in medicine.

Knights of ALCANTARA, a military order in Spain. The knights of this order make a very conſiderable figure in the hiſtory of the Spaniſh expeditions againſt the Moors.

ALCE, in natural hiſtory, the name of an animal, generally called the elk. See the article ELK.

ALCEA, *Vervain Mallow*, in botany, a plant with a woody whitiſh root, from whence proceed ſeveral ſtalks to the height of about three feet round, full of pith, and thinly beſet with longiſh hair. The leaves that proceed from the root and lower part of the ſtalks are roundiſh, with inciſſures on the edges; but thoſe that grow near the top, and placed alternately, are remarkably jagged, of a blackiſh green colour, and hairy, particularly on the lower part. The flowers are like thoſe of mallows, and of a purpliſh fleſh colour, though they are ſometimes white: they are ſucceeded by ſeeds, which are black when ripe, and ſhaped like thoſe of mallows. The medicinal virtues of this plant are the ſame with thoſe of mallow. *Brookes's Natural Hiſtory.*

ALCHEMIST, a perſon who profeſſes, or practiſes, the art of alchemy.

ALCHEMY, the ſublimer, or more abſtruſe, parts of chemiſtry. See the article CHEMISTRY.

The word is formed from the Arabic particle *al*, which ſignifies ſublime, or excellent, and *chemy*, chemiſtry. The term therefore properly ſignifies *the ſublime chemiſtry*, or *the chemiſtry*, by way of excellence.

ALCIS, in mythology, the name under which Minerva was worſhipped by the Macedonians.

ALCMANIAN, in ancient lyric poetry, a ſpecies of verſe conſiſting of two dactyls and two trochees. The following is of this kind.

Virgini | bus pue | riſque | canto.

ALCOA *Arbor*, the name of a tree found in St. Helena, the wood of which reſembles ebony; but it is not known to what genus it belongs.

ALCOHOL, in chemiſtry, ſignifies ſpirit of wine rectified by repeated diſtillations, till it has acquired the utmoſt ſubtilty and perfection poſſible.

By theſe repeated rectifications, it is not only freed from its redundant phlegm, but alſo from ſome particles of acid and oil, which, though much leſs volatile than itſelf, aſcends with it in the firſt diſtillation; nor is it poſſible wholly to avoid this inconvenience. See SPIRIT.

ALCOHOL alſo ſignifies a very fine impalpable powder. The oriental ladies uſe antimony, reduced to an impalpable powder, for blacking their eye-lids, and call this powder alcohol.

ALCOLA, a term uſed by ſome alchemiſts for the tartar of urine, found in ſmall grains of a reddiſh colour.

ALCORON, AL-CORAN, or AL-KORAN, the ſcripture, or bible, of the Mahometans.

The word is compounded of the Arabic particle *al*, and *coran*, or *koran*, derived from the verb *caraa*, or *karaa*, to read; the true ſenſe therefore of the word is, *the reading*, or that which ought to be read.

The alcoran is divided into 114 large portions, of very unequal length, which we call chapters, but the Arabians *ſowar*, which properly ſignifies a row, or ſeries. Theſe chapters, in the manuſcript copies, are not diſtinguiſhed by their numerical order, but by particular titles, which are ſometimes taken from ſome principal matter treated of, but generally from the firſt word of note that occurs.

Every chapter is ſubdivided into ſmaller portions, which we uſually call verſes, but the Arabians, *aiat*, which ſignifies ſigns or wonders; ſuch are the ſecrets of God, his attributes, works, &c. delivered in thoſe verſes.

The alcoran is univerſally allowed to be written in the pureſt and moſt elegant language, and to be the ſtandard of the Arabic tongue. The ſtile is, in general, beautiful and fluent, eſpecially where it imitates the prophetic manner, and Scripture phraſes. It is conciſe and often obſcure, adorned with bold figures after the Eaſtern manner, enlivened with florid and ſententious expreſſions, and in many places, eſpecially where the majeſty and attributes of God are deſcribed, ſublime and magnificent.

The general deſign of the alcoran was, to unite the profeſſors of the three different religions then followed in the populous country of Arabia, who, for the moſt part, lived promiſcuouſly, and wandered without guides, the far greater number being Pagans, and the reſt Jews and Chriſtians. In order to perform this, Mahomet pretended to be the ambaſſador of God, who, after the repeated admonitions, promiſes, and threatenings of former ages, had ſent him to eſtabliſh the true religion upon earth by force of arms, and appointed him chief pontiff in ſpiritual, and ſupreme prince in temporal affairs.

The great doctrine of the alcoran is the unity of God; and to reſtore that fundamental principle of true religion, Mahomet pretended was the chief end of his miſſion. But there are many occaſional paſſages in it, relating to particular emergencies; for whenever any thing happened to perplex the falſe prophet, he always had recourſe to a new revelation; and hence there are ſeveral paſſages in the alcoran contradictory to one another. The Mahometan doctors, however, obviate any objection that might be raiſed on this ſubject, by ſaying, that God commanded ſeveral things in the alcoran, which, for good reaſons, were afterwards revoked and abrogated.

That Mahomet was really the chief contriver of the alcoran is beyond diſpute; though it is highly probable, that he had no ſmall aſſiſtance in his deſign from others; particularly from one Sergius, a Neſtorian monk, and a Jew named Abdallah Ebn Salâm. The Mahommedans however abſolutely deny that the alcoran was compoſed either by their prophet himſelf, or any other perſon: it being their general and orthodox belief, that it is not only of divine original, but even eternal and uncreated, remaining, as ſome of them expreſs it, in the very eſſence of God; that the firſt tranſcript has been from everlaſting by God's throne, written on a table of vaſt bigneſs; that a copy from this table, in one volume on paper, was, by the miniſtry of the angel Gabriel, ſent down to the loweſt heaven in the month of Ramadan, whence Gabriel revealed it by parcels, ſome at Mecca, and ſome at Medina, at different times during the ſpace of twenty years, as the exigency of affairs required; giving Mahomet, however, the ſatisfaction of ſeeing the whole once a year. They add, that this original copy was bound in ſilk, and adorned with gold and precious ſtones of paradiſe.

Hence it is eaſy to conceive, that this book is held in the higheſt eſteem and reverence among the Mahometans. They dare not ſo much as touch it without being legally purified. They read it with great attention and reſpect, never holding it below their girdles. They ſwear by it, conſult it on the moſt weighty occaſions, carry it with them to war, write ſentences of it in their banners, adorn it with gold and precious ſtones, and knowingly, do not ſuffer it to be in the poſſeſſion of any of a different perſuaſion.

The interpreters of the alcoran unanimouſly agree, that the moſt eloquent paſſage of this whole book is that which is contained in the chapter Houd, where God is introduced bidding the waters of the deluge ceaſe. The words are theſe: "Earth, ſwallow up the waters; "Heaven, draw up thoſe thou haſt poured out: imme-"diately the waters retreated, the command of God "was obeyed, the ark reſted on the mountains, and "theſe words were heard, Wo to the wicked!"

The ſame interpreters remark likewiſe, that the moſt excellent moral of the whole alcoran is comprized in this verſe of the chapter Aaraf: "Pardon eaſily, do "good to all, and contend not with the ignorant." They add, that Mahomet demanded of the angel Gabriel a more ample explication of this verſe, which was given him in theſe words: "Seek after him who drives "you away; give to him who takes from you; pardon "him who offends you; for God would have you plant "in your ſouls the ſeeds of the greateſt perfections." This morality is plainly borrowed from the evangelical precept of rendering good for evil.

ALCOVE, among builders, ſignifies a receſs, or part of a chamber, ſeparated by an eſtrade, or partition of columns, and other correſponding ornaments, in which either a bed of ſtate is placed, or ſeats to entertain company.

ALCYOPIUM, in botany, a genus of ſubmarine plants, conſiſting of a rigid fibroſe ſubſtance, diſpoſed in various forms, and ſometimes coated over with a cruſt of a ſimilar, but more compact matter than the reſt. None of the ſpecies of this genus has either any viſible flowers or ſeeds.

ALCYONIUM is alſo uſed to ſignify various other ſubſtances, particularly a kind of white coral or aſtroites, frequently found foſſil in England.

ALDEBARAN, in aſtronomy, a ſtar of the firſt magnitude, called in Engliſh the Bull's-eye, as making the eye of the conſtellation Taurus. Its longitude is 6 deg. 32 min. 0 ſec. of Gemini, and its latitude 5 deg. 29 min. 49 ſec. ſouth.

ALDER-TREE, *Alnus*, in botany, the name of a genus of trees whoſe characters are theſe: the flower is of the amentaceous kind, being compoſed of ſeveral apices, ariſing from four-leaved cups; theſe are affixed in a cluſtering manner to an axis, but theſe are barren. The young fruit appears in a different part of the tree, is of a ſquamoſe ſtructure, and loaded with embryo ſeeds; this finally increaſes in ſize, and becomes a regular fruit, containing a number of compreſſed ſeeds. *Miller's Dict.*

There are eight ſpecies of this plant enumerated by botanical authors; but the common alder is generally meant by the name.

There is a peculiar beneficial property belonging to this plant, for no beaſt will crop it, be it young or old, which ſaves the great charge of fencing it after planting. Their propagation is the ſame as the poplar, and, where the place is too wet for that, the alder will flouriſh and become large trees, pollards, or poles for hedges; in ſhort, there is none of the aquatic tribe will raiſe more money and ſooner than the alder, in wet meadow hedges, and in boggy, mooriſh ground, nor make ſtronger and quicker fences than this excellent plant.

This aquatic will thrive but poorly when raiſed from truncheons, nor much better from the wild ſet or ſucker, which it produces but few of. But there is a way to do this much more to the purpoſe, and that is thus: firſt, prepare a bed of well-manured fine mould, then lay the full ripe ſeed at a due diſtance from the fire, or in the ſun, and it will cauſe them to open like the fir pine-apple; then ſow the ſeeds in the bed, and you will have abundance of young plants, that on ſetting out will be ſure to grow, if rightly managed: at Midſummer cut away the ſmall ſide-ſhoots of this tree, which will prevent their ſecond growth; but if they are large, you muſt not do it, becauſe it will then make the ſap run out too much, and damage the tree. This is of great conſequence; for, by ſo doing, the large ſide-arms are prevented in their growth, which often cauſes knobs and wens that leſſen the value of their wood. *Ellis's Timber-tree improved.*

ALDERMAN, the ſecond degree of nobility among the Anglo-Saxons, and now the ſecond degree in cities or corporations; the mayor being the head, the aldermen the next, and the common-council the third, or loweſt degree.

The word is derived from the Saxon, earlderman; that is, a ſenior, or alderman, which, by degrees, came to ſtand for perſons of the greateſt diſtinction, becauſe ſuch were choſen to diſcharge the higheſt offices, being thoſe whoſe long experience rendered them moſt capable, and whoſe birth and fortune made them moſt conſpicuous; and as they were generally intruſted with the government of the counties, inſtead of ſaying the governor, it was ſaid the earlderman of ſuch a county; and by degrees this word came to ſignify the governor of a county, or city. While the heptarchy laſted, theſe officers were only during the king's pleaſure; at laſt they were for life, at leaſt for the moſt part. After the Danes were ſettled in England, the title of earlderman was changed into that of earl, and the Normans introduced that of count, which, though different in its original ſignification, meant however the ſame dignity.

At this time aldermen are aſſociates to the mayor, or civil magiſtrates of moſt of our municipal or corporate cities or towns, who form a kind of council, and regulate matters according to the policy of the place: ſometimes they alſo take cognizance of civil and criminal matters, but very rarely, and in particular caſes: their number is not limited, being in ſome places ſix, and others twenty-ſix, out of which are annually choſen the mayors, or chief magiſtrates, who, at the expiration of their mayoralty, devolve again into aldermen.

An alderman ought to be an inhabitant of the place, and reſident where he is choſe; and if he removes, he is incapable of doing his duty in the government of the place, for which he may be disfranchiſed.

ALE, a fermented liquor obtained from an infuſion of malt, and differing only from beer in having a leſs proportion of hops. See the article BREWING and FERMENTATION.

There are various ſorts of ale known in England, particularly pale and brown; the former is brewed from malt ſlightly dried, and is eſteemed more viſcid than the latter, which is made from malt more highly dried or roaſted.

Medicated ALES, thoſe wherein medicinal herbs have been infuſed, or added during the fermentation.

Gill ALE, is that in which the dried leaves of gill or ground-ivy have been infuſed. It is eſteemed abſterſive and vulnerary, and conſequently good in diſorders of the breaſt and obſtructions of the viſcera.

ALE-CONNER, an officer in London, who inſpects the meaſures uſed in public houſes.

There are four ale-conners, who are all choſen by the common-council of the city.

ALE-SILVER, a tax paid annually to the Lord-mayor of London, by all who ſell ale within the city.

ALEA, a ſurname given to Minerva by Aleus, king of Arcadia, who built a temple to that goddeſs in the city of Tegea, the capital of his kingdom. In that temple were preſerved the hide and tuſks of the wild boar Calydon.

ALECTO, one of the three furies of Hell, the daughter of Acheron and Night. See FURIES.

The word is Greek, and ſignifies *envy.*

ALECTORIA, in natural hiſtory, a ſtone ſaid to be formed in the ſtomach, liver, or rather gall-bladder of old cocks; and to which the ancients attributed many fabulous virtues.

The word is Greek, and derived from αλεχτρον, a cock.

ALECTROMANCIA, in antiquity, a ſpecies of divination performed by means of a cock, in the following manner: a circle being deſcribed on the ground, was divided into twenty-four equal portions, in each of which was written one of the letters of the alphabet, and a grain of wheat placed on each of the letters. This being finiſhed, a cock was turned looſe in the circle, and particular notice taken of the grains picked up by the bird; becauſe the letters under them being formed into a word, gave an anſwer to the queſtion.

The word is Greek, and compounded of αλεχτρον, a cock, and μαντεια, divination.

A-LEE, in navigation, is a term only uſed when the wind, croſſing or flanking the line of a ſhip's courſe, preſſes upon the maſts and ſails ſo as to make her incline to one ſide, which is called the lee-ſide: hence when the helm is moved over to this ſide it is ſaid to be a-lee, or hard a-lee.

ALEGAR, a kind of vinegar made of ale.

ALEMBIC, a chemical veſſel uſually made of glaſs, or copper, for condenſing the vapours that riſe in diſtillation; for the alembic is properly the head or upper part of the apparatus uſed in diſtilling; though it is often uſed to ſignify the whole. See the articles STILL, and DISTILLATION.

ALEPH, the name of the firſt letter in the Hebrew alphabet, from which the *alpha* of the Syrians and Greeks was formed.

The word properly ſignifies chief, prince, or thouſand. There are ſome of the Pſalms and other parts of Scripture which begin with Aleph, and the other verſes of them are continued with the other letters of the alphabet. The modern Jews uſe their letters as cyphers. Aleph ſtands for one; Beth for two; Gimel for three, &c.

ALEXANDRINE, in poetry, a kind of verſe, conſiſting of twelve, or thirteen ſyllables alternately; ſo called from a poem on the Life of Alexander, written in this kind of verſe by ſome French poet.

ALEXIPHARMICS, in medicine, are properly remedies for expelling or preventing the ill effects of poiſon:

but ſome of the moderns having imagined that the animal ſpirits, in acute diſtempers, were affected by a malignant poiſon, the term has been underſtood to mean medicines adapted to expel this poiſon by the cutaneous pores, in the form of ſweat. In this ſenſe, alexipharmics are the ſame as ſudorifics.

The word is formed from the Greek, αλεξω, to expel, and φαρμακον, a poiſon.

The moſt efficacious medicines of this kind owe the virtue of their operation to the power they poſſeſs of increaſing the ſyſtoltic motion of the heart, and the elaſticity of the arteries, as to the number and force of their vibrations, by which means a greater velocity being added to the circulation, they protrude the perſpirable matter through the outward and porous ſubſtances of the ſkin. This they perform either by a ſubtile, acid, hot oil; or by a volatile empyreumatic ſalt of an igneous nature; or by an acrid, reſinous ſalt, more or leſs fixed; or, laſtly, they act, and that very powerfully, by means of a very fine mineral ſalt and ſulphur, by which they rouſe the nervous fibres to a violent motion.

The moſt active ſudorifics, or alexipharmics, rarely find a place in medicine, and are not to be adminiſtred but with ſingular caution: for a ſweat never riſes in a healthful and natural ſtate, unleſs the blood is put into an extraordinary motion; nor, when this happens, is it a ſign of health, like inſenſible perſpiration, the matter of which is void of acrimony, watery, reſembling the nutritious juices, and almoſt deſtitute of taſte or ſmell, differing very much from ſweat, which is of a ſalt taſte, a fœtid ſmell, and approaches the nature of urine. Beſides, the ſudorifics excite a great commotion, and notable orgaſm; for they act not with moderation but rapidity: whence it comes to paſs, that in bodies replete with blood, or contaminated ſerum, by impelling the fluids with too much violence to the ſmall and narrow veſſels, they bring on dangerous and acute ſymptoms, occaſioned by the inflammation and redundance of humours. But they are particularly hurtful, where the primæ viæ are obſtructed by a load of vitious humours, where the body is coſtive, and when they are adminiſtred immediately after a violent fit of anger. *Hoffman.*

ALEXITERIAL, among phyſicians, a term of much the ſame import with alexipharmic; though ſometimes uſed in a ſynonymous ſenſe with amulet.

ALFAQUES, among the Moors, the name generally uſed for their clergy, or thoſe who teach the Mahometan religion, in oppoſition to the Morabites, who anſwer to the Monks among the Chriſtians.

ALFET, in our old cuſtoms, denotes a cauldron full of boiling water, wherein an accuſed perſon, by way of trial or purgation, plunged his arm up to the elbow.

ALGA, in botany, a genus of ſubmarine plants, called in Engliſh, graſs-wreck, and compoſed of long ſlender leaves of a duſky-green colour, very much reſembling ſome kinds of graſs.

Authors enumerate ſeveral ſpecies of alga, the moſt conſiderable of which is the alga-marina, ſo much uſed in the glaſs trade.

ALGAROT, or ALGARET, in chemiſtry, an emetic powder prepared from regulus of antimony. See the article ANTIMONY.

ALGEBRA, a general method of reſolving problems by means of equations.

With regard to the etymology of the word algebra, it is much conteſted by the critics. Menage derives the word from the Arabic *algiabarat*, which ſignifies the reſtitution of any thing broken; ſuppoſing that the principal part of *algebra* is the conſideration of broken numbers. Others rather borrow it from the Spaniſh, *algebriſta*, a perſon who replaces diſlocated bones; adding, that algebra has nothing to do with fraction. Some, with M. d'Herbelot, are of opinion, that algebra takes its name from Geber, a celebrated philoſopher, chemiſt, and mathematician, whom the Arabs call Giaber, and who is ſuppoſed to have been the inventor. Others from gefr, a kind of parchment made of the ſkin of a camel, whereon Ali and Giafar Sadek wrote, in myſtic characters, the fate of Mahometaniſm, and the grand events that were to happen till the end of the world. But others, with more probability, derive it from *geber*, a word whence, by prefixing the article *al*, we have formed algebra, which is pure Arabic, and properly ſignifies the reduction of fractions to a whole number. However, the Arabs, it is to be obſerved, never uſe the word algebra alone, to expreſs what we mean by it; but always add to it the word *macabelah*, which ſignifies oppoſition and compariſon: thus *algebra-almacabelah*, is what we properly call algebra.

Some authors define algebra, the art of ſolving mathematical problems; but this is rather the idea of analyſis, or the analytic art. The Arabs call it, *the art of reſtitution and compariſon*, or, *the art of reſolution and equation.* Lucas de Burgo, the firſt European who wrote of algebra, calls it, *regula rei & cenſus*, that is, the rule of the root and its ſquare; the root with them being called *res*, and the ſquare *cenſus*. Others call it *ſpecious arithmetic*, and others, *univerſal arithmetic.*

It is highly probable that the Indians or Arabians firſt invented this noble art; for it may reaſonably be ſuppoſed, that the ancient Greeks were ignorant of it, becauſe Pappus, in his Mathematical Collections, where he enumerates their analyſis, makes no mention of any thing like it; and, beſides, ſpeaks of a local problem, began by Euclid, and continued by Apollonius, which none of them could fully reſolve, which doubtleſs they might eaſily have done, had they known any thing of algebra.

Diaphantus was the firſt Greek writer of algebra, who publiſhed thirteen books about the year 800, though only ſix of them were tranſlated into Latin, by Xylander, in 1575; and afterwards, viz. anno 1621, in Greek and Latin by M. Bachet and Fermat, with additions of their own. This algebra of Diaphantus's only extends to the ſolution of arithmetical indeterminate problems.

Before this tranſlation of Diaphantus came out, Lucas Paccіolus, or Lucas de Burgo, a minorite friar, publiſhed at Venice, in the year 1494, an Italian Treatiſe of Algebra. This author makes mention of Leonardus Piſanus, and ſome others, of whom he had learned the art; but we have none of their writings. He adds, that algebra came originally from the Arabs, and never mentions Diaphantus; which makes it probable, that that author was not at that time known in Europe. His algebra goes no farther than ſimple and quadratic equations.

After Pacciolus appeared Stifelius, a good author; but neither did he advance any farther.

After him, came Scipio Ferreus, Cardan, Tartagila, and ſome others, who reached as far as the ſolution of ſome cubic equations. Bombelli followed theſe, and went a little farther. At laſt came Nunnius, Ramus, Schoner, Salignac, Clavius, &c. who all of them took different courſes, but none of them went beyond quadratics.

In 1590, Vieta entered upon the ſtage, and introduced what he called his *Specious Arithmetic*, which conſiſts in denoting the quantities, both known and unknown, by ſymbols or letters. He alſo introduced an ingenious method of extracting the roots of equations, by approximations, ſince greatly improved and facilitated by Raphſon, Halley, Simpſon, and others.

Vieta was followed by Oughtred, who, in his *Clavis Mathematica*, printed in 1631, improved Vieta's method, and invented ſeveral compendious characters, to ſhew the ſums, differences, rectangles, ſquares, cubes, &c.

Harriot, another Engliſhman, cotemporary with Oughtred, left ſeveral treatiſes at his death; and among the reſt, an Analyſis, or Algebra, which was printed in 1631, where Vieta's method is brought into a ſtill more commodious form, and is much eſteemed to this day.

In 1657, Des Cartes publiſhed his geometry, wherein he made uſe of the literal calculus and the algebraic rules of Harriot; and as Oughtred, in his *Clavis*, and Marin. Ghetaldus, in his books of Mathematical Compoſition and Reſolution, publiſhed in 1630, applied Vieta's Arithmetic to elementary geometry, and gave the conſtruction of ſimple and quadratic equations; ſo Des Cartes applied Harriot's method to the higher geometry, explaining the nature of curves by equations, and adding the conſtructions of cubic, biquadratic, and other higher equations.

Des Cartes's rule for conſtructing cubic and biquadratic equations, was farther improved by Thomas Baker, in his *Clavis Geometrica Catholica*, publiſhed in 1684, and the foundation of ſuch conſtructions, with the application of algebra to the quadratures of curves, queſtions *de maximis & minimis*, the centrobaryc method of Guldinus, &c. was given by R. Sluſius, in 1668; as alſo by Fermat, in his *Opera Mathematica*; Roberval, in the *Mem. de Mathem. & de Phyſique*; and Barrow in his *Lect. Geomet.* In 1708 algebra was applied to the laws of chance and gaming, by R. de Montmort; and ſince by de Moivre and James Bernoulli.

Thus much for the progreſs of algebra. The elements of the art were compiled and publiſhed by Kerſey in 1671, wherein the ſpecious arithmetic, and the nature of equations are largely explained, and illuſtrated by variety of examples: the whole ſubſtance of Diaphantus is here delivered, and many things added concerning mathematical compoſition and reſolution, from Ghetaldus. The like has been ſince done by Preſtet in 1694, and by Ozanam in 1703: but theſe authors omit the application of algebra to geometry, which defect is ſupplied by Guiſnec in a French Treatiſe expreſly on the ſubject, publiſhed in 1704; and l'Hopital, in his Analytical Treatiſe of the Conic Sections, in 1707. The rules of algebra are alſo compendiouſly delivered by Sir Iſaac Newton, in his *Arithmetica Univerſalis*, firſt publiſhed in 1707, which abounds in ſelect examples, and contains ſeveral rules and methods invented by the author.

Algebra is of two kinds, *numeral* and *literal*.

Numeral, or *Vulgar* ALGEBRA, is that of the ancients, which only had place in the reſolution of arithmetical queſtions. In this, the quantity ſought is repreſented by ſome letter or character; but all the given quantities are expreſſed by numbers.

Literal, or *Specious* ALGEBRA, or the *New* ALGEBRA, is that wherein the given or known quantities, as well as the unknown, are all expreſſed or repreſented by their ſpecies, or letters of the alphabet.

This eaſes the memory and imagination of that vaſt ſtreſs or effort required to keep ſeveral matters, neceſſary for the diſcovery of the truth in hand, preſent to the mind: for which reaſon this art may be properly denominated metaphyſical geometry. Specious algebra is not, like the numeral, confined to certain kinds of problems; but ſerves univerſally for the inveſtigation or invention of theorems, as well as the ſolution and demonſtration of all kinds of problems, both arithmetical and geometrical. The letters uſed in algebra do each ſeparately repreſent either lines or numbers, as the problem is arithmetical or geometrical; and together, they repreſent planes, ſolids, and powers, more or leſs high, as the letters are in a greater or leſs number: for inſtance, if there be two letters, ab, they repreſent a rectangle, whoſe two ſides are expreſſed, one by the letter a, and the other by b; ſo that by their mutual multiplication they produce the plane ab. When the ſame letter is repeated twice, as aa, they denote a ſquare. Three letters abc, repreſent a ſolid, or a rectangle parallelopiped, whoſe three dimenſions are expreſſed by the three letters a, b, c; the length by a, the breadth by b, and the depth by c; ſo that by their mutual multiplication they produce the ſolid abc.

As the multiplication of dimenſions is expreſſed by the multiplication of letters, and as the number of thoſe may be ſo great as to become incommodious; the method is, only to write down the root, and on the right hand to write the index of the power, that is, the number of letters whereof the power to be expreſſed does conſiſt; as a^2, a^3, a^4, a^5; the laſt of which ſignifies as much as a, multiplied five times into itſelf; and ſo of the reſt.

For the ſymbols, characters, &c. uſed in algebra, with their application, &c. ſee the articles CHARACTER, and QUANTITY.

For the method of performing the ſeveral operations in algebra, ſee ADDITION, SUBTRACTION, and MULTIPLICATION.

ALGEBRA has alſo been applied to the conſideration and calculus of infinites; from whence a new and extenſive branch of knowledge has ariſen, called the Doctrine of Fluxions, or Analyſis of Infinites, or the *Calculus Differentialis*. See FLUXIONS. The principal authors on this ſubject, ſee under the article ANALYSIS.

ALGEBRAICAL, ſomething that relates to algebra. Thus we ſay, algebraical characters, or ſymbols, curves, ſolutions, &c. See CHARACTER.

ALGEBRAICAL *Curve* is a curve wherein the relation of the abſciſſes to the ordinates may be defined by an algebraical equation. Theſe are alſo called geometrical lines, or curves. Algebraical curves ſtand contradiſtinguiſhed to mechanical or tranſcendental ones. See MECHANICAL and TRANSCENDENTAL.

ALGEBRAIST, a perſon ſkilled in the ſcience of algebra.

ALGENEB, a fixed ſtar of the ſecond magnitude in Perſeus's right ſide; its longitude is 27°, 46′, 12″, of Taurus, and its latitude 30°, 05′, 28″, north, according to Mr. Flamſtead's catalogue.

ALGOIDES, a name uſed by Vaillant for a genus of plants, called, by Linnæus, zannichellia. See ZANNICHELLIA.

ALGOL, a fixed ſtar of the third magnitude, called Maduſa's Head, in the conſtellation Perſeus; its longitude is 21°, 50′, 42″, of Taurus, and its latitude 22°, 23′, 47″, north, according to Flamſtead's catalogue.

ALGOR, among medical writers implies, an unuſual coldneſs or chillneſs in any part of the body.

ALGORITHM, the art of numerical computation, and particularly means the five rules of arithmetic, called numeration, addition, ſubtraction, multiplication, and diviſion.

The word is Arabic, and properly ſignifies the art of computing wih accuracy and facility.

The Spaniſh writers uſe the word algorithm to ſignify the practice of algebra.

ALGUAZIL, in the Spaniſh police, an officer whoſe buſineſs it is to carry the decrees of the judges into execution.

The word is originally Arabic, and received by the Spaniards from the Saracens, or Moors, who reigned a long time in Spain.

ALHANDEL, the Arabic name for colocynth. See COLOCYNTH.

ALHEAL, in botany, a name given to ſeveral plants, on account of their medicinal virtues. See PANAX.

ALHIDADE, or ALIDADE, the Arabic name of the index or diopter of a mathematical inſtrument for taking heights and diſtances.

ALIAS, a ſecond or further writ iſſued from the courts of Weſtminſter, after a capias, &c. ſued out without effect.

ALIBI, in law, implies the abſence of the accuſed party; or his being at a diſtance from the place where the fact was committed, at the very time mentioned in the indictment.

The word is Latin, and properly ſignifies elſewhere.

ALIEN, in law, implies a perſon born in a ſtrange country, not within the king's allegiance, in contradiſtinction to a denizon, or natural ſubject.

The word is formed from the Latin, *alius*, another; q. d. one born in another country.

An alien is incapable of inheriting lands in England, till naturalized by an act of parliament. No alien is entitled to vote at the election of members of parliament; nor can he enjoy any office, or be returned on any jury, unleſs where an alien is party in a cauſe, when the inqueſt is compoſed of an equal number of denizens and aliens.

The reaſons for eſtabliſhing theſe laws were, that every man is preſumed to bear faith and love to that prince and country where he received protection during his infancy; and that one prince might not ſettle ſpies in another's country; but chiefly that the rents and revenues of the country might not be drawn to the ſubjects of another.

Some have thought that the laws againſt aliens were introduced in the time of Henry II. when a law was made at the parliament of Wallingford, for the expulſion of ſtrangers, in order to drive away the Flemings and Picards, introduced into the kingdom by the wars of king Stephen. Others have thought that the original of this law was more ancient; and that it is an original branch of the feudal law; for by that law no man can purchaſe any lands but he muſt be obliged to do fealty to the lords of whom the lands are holden; ſo that an alien that owned a previous faith to another prince, could not take an oath of fidelity in another ſovereign's dominions.

Among the Romans, only the Cives Romani were eſteemed freemen; but, when their territories increaſed, all the Italians were made free, under the name of Latines, though they had not the privilege of wearing gold rings, till the name of Juſtinian. Afterwards all born within the pale of the empire were conſidered as citizens. *Cunningham's Law Dict.*

Alien-Duty, an impoſt laid on all goods imported by aliens, over and above the duty for ſuch goods imported by Britiſh ſubjects, and on Britiſh bottoms.

Alien-Priories, a kind of inferior monaſteries, formerly very numerous in England, and ſo called from their belonging to foreign abbies.

ALIENATION, in law, implies the act of making over a perſon's property in lands, tenements, &c. to another.

ALIFORMIS, in anatomy, the name of a pair of muſcles ariſing from the pterygoide bones, the proceſs of the os cuneiforme, with a beginning partly nervous, and partly fleſhy, and ending in the neck of the lower jaw.

The word is Latin, and compounded of *ala*, a wing, and *forma*, reſemblance.

Aliformis Processus, a name ſometimes given to the prominence of the os cuneiforme.

ALIMENT, in a general ſenſe, implies, whatever contributes to the nouriſhment of an animal or vegetable body.

Aliment, among phyſicians, whatever is capable of nouriſhing an animal body.

The loſs which we ſuſtain daily makes it neceſſary that it ſhould be repaired by ſubſtances analogous to thoſe of our body, ſuch as aliment and drink, the ſtimulus to which is hunger and thirſt; wherefore it is neceſſary to know in general their kinds and principal qualities, in order to make a proper choice.

Solid Aliments are taken from ſeeds, fruits, leaves, ſtalks, and roots; of all which the ſeed is the moſt laboured, and contains a mealy and milky ſubſtance; from whence a ſoft oil may be drawn, friendly to human bodies.

The principal and moſt general aliment is bread, which is made of wheat, rye, barley, and Turkey corn. That of wheat is moſt nouriſhing; barley is dry, and rye is laxative. The cruſt is moſt eaſy of digeſtion; the crum is more oily and heavy.

The other farinaceous ſubſtances are beans, peaſe, and lentils, which nouriſh much, but are heavy, windy, and viſcous; and conſequently, by conſtant uſe are apt to cauſe obſtructions.

Rice, barley, and oats, properly prepared, are moiſtening, emollient, and reſtorative. Nuts, almonds, and cheſnuts, are full of a nouriſhing oil, but are hard of digeſtion.

Fruits which are pulpous and tart, abound with water, and are refreſhing, moiſtening and ſedative; appeaſing the too rapid motion of the blood, quenching thirſt, digeſting eaſily; ſuch as ſtrawberries, gooſeberries, currants, apricots, and figs; as alſo peaches, pears, and apples. Theſe ſhould be eaten ripe, and in a ſmall quantity; but they are windy, and therefore are beſt boiled, or baked, and made into ſweetmeats.

Pot-herbs and roots are leſs nouriſhing than the mealy ſubſtances. Lettuce, ſuccory, ſorrel, purſlain, refreſh, moiſten, looſen the belly, and appeaſe the orgaſm of the blood. Artichokes, cellery, creſſes, aſparagus, parſley, are a little heating. Truffles, champignons, garlic, ſhallots, pepper, cloves, nutmegs, muſtard, heat very much.

Animals are either terreſtrial, volatile, aquatic, or amphibious. Theſe differ greatly with regard to their kind, age, manner of living, and ſubſtance.

Fiſh nouriſh the leaſt of all animals, becauſe they abound with phlegm. Young animals have a plenty of a ſoft and nouriſhing juice, but that of the older is more nouriſhing. The juices of the old are ſpirituous, gelatinous, and agreeable to the taſte; but the fleſh is hard, and difficult of digeſtion.

Wild animals are more light and digeſtible than the tame. Their white parts contain a very ſucculent ſubſtance of tender fibres, and yield a ſoft aliment, and are eaſy of digeſtion.

Liquid Aliments are milk, eggs, chocolate, ſoops, broths, &c.

Milk is properly nothing but chyle, and conſequently does not need any great preparation in the ſtomach. It is a good aliment for perſons whoſe ſtomachs are languid, and for children.

New laid eggs yield very good nouriſhment, are eaſy of digeſtion, and agree with perſons of exhauſted bodies, and thoſe that are old.

Chocolate is a very agreeable liquor, and nouriſhing; ſtrengthens the ſtomach, reſtores the body, helps the digeſtion, and ſoftens ſharp humours. It is proper for perſons of a weak ſtomach.

Drinks reſtore the fluid parts of the body; they are a vehicle for other aliments, and render the digeſtion eaſy. Water is the principal, moſt ſalutary, and moſt neceſſary for life, of which ſoft water is the beſt, and which lathers readily with ſoap. It is the greateſt diſſolvent that we have. Water alone has cured many indiſpoſitions, but too much relaxes and weakens the ſolids, and cauſes many infirmities.

Wine taken too freely is prejudicial to health; but moderately, it ſtrengthens the ſolids, and facilitates digeſtion; its exceſs, as well as all other ſpirituous liquors, harden the fibres, affect the nerves, diminiſh the ſecretions, deſtroy the appetite, and induce chronical diſeaſes.

That malt liquor is accounted beſt that is ſpecifically lighteſt, and not ſaturated with too groſs a ſubſtance, for then it does not offend the ſtomach, but paſſes readily through the emunctories of the body, and particularly by urine. The beſt kind of beer does not render the head heavy, nor grow ſour upon the ſtomach, nor inflates the hypochondria. This depends greatly upon the goodneſs of the water, the proper boiling of the ingredients, and the due fermentation.

All thick, muddy, heavy, ſtale beer, not ſufficiently boiled, offends the head, generates wind, obſtructions, the ſtrangury, aſthma, and the colic.

Tea promotes perſpiration, ſtrengthens and clears the ſtomach, helps digeſtion.

Coffee is taken after dinner to haſten the digeſtion, and allay the fumes of wine. Moderately uſed it ſubtilizes the humours, but its exceſs agitates the blood, cauſes watching, and promotes hæmorrhages.

Broth, or ſoup, abounds with a ſoft, moiſtening, and nouriſhing jelly, whence they are good reſtoratives. Meat that is roaſted contains an excellent nouriſhing juice, the moiſt parts being diſſipated by the fire.

Things that are fried are only proper for good ſtomachs.

Spice, vinegar, &c. in a ſmall quantity, may correct the faults of the aliment, but are pernicious when uſed to create an appetite; whence made-diſhes are commonly bad. The appetite, excited by the quality and diverſity of the viands, provokes perſons to eat more than they ought; which cauſes indigeſtions, frequent indiſpoſitions, and ſometimes dangerous diſeaſes: therefore the ſkill of the cooks of theſe times contribute greatly to ſhorten their maſters lives.

The method of preſerving health therefore is to live upon plain ſimple aliment, lightly ſeaſoned, and in quantity agreeable to the age, ſtrength of the ſtomach, ſeaſon of the year, ſex, conſtitution, and chiefly to what nature is found by experience to require: for it is as great a fault to take too much as too little. Perfect digeſtion is the beſt rule for regulating a meal, eſpecially if the perſon is more briſk and lively after a repaſt than before.

We have examples of many perſons, who by their temperance have lived to a very advanced age; wherefore, thoſe that are fond of life and health ſhould imitate their regimen. Exceſſes in eating and drinking are extremely pernicious.

Perſons of a delicate conſtitution, or who are juſt recovered

covered from a diſeaſe, ſhould uſe ſoft light aliments agreeable to the ſtomach; for they make the beſt chyle.

Acid, tenacious, viſcous aliment, pies of all kinds; things that are fat, and of a blackiſh ſubſtance, are generally unfit for chylification, or render the chyle bad.

Strong, robuſt, young perſons, who uſe much exerciſe, ought to eat more than others; and may be more free with the groſſer kind of aliment; for their ſtomachs being ſtrong, the lighter kind of food would digeſt too eaſily, and be diſſipated too ſoon.

Children, whoſe ſtomachs are weak, and veſſels fine, ought to uſe a light, ſlender, thin, ſoft aliment, eaſy of digeſtion; wherefore infants ſhould be fed with fluid milk, to avoid cauſing obſtructions in their fine and delicate veſſels. Conſequently, the milk of a nurſe newly brought to bed is more agreeable to infants than that of one who has been delivered five or ſix months, and whoſe milk begins to have too great a conſiſtence. Nurſes ſhould obſerve an exact regimen, and ſhun all ſorts of violent paſſions; for they diſturb digeſtion, and communicate their bad effects to their children. When infants are weaned, they ſhould not be accuſtomed to ſpirituous liquors and ſtrong food, eſpecially the ſalt and ſmoke-dried, which are hard of digeſtion, and yield bad nouriſhment. The beſt method is to eat little at a time and often.

In old age the fluids are more thick, the ſecretions ſlow, and the ſolids more ſtiff than in youth; wherefore they require leſs food, and of a more ſoft, nouriſhing, moiſtening kind, eaſy of digeſtion, and not too much at a time, eſpecially in the evening.

At all times of life, but eſpecially in old age, the conſtant and immoderate uſe of ſalt and ſmoke-dried meat, acid and aromatic vegetables, as well as ſpirituous liquors, tend to harden and ſtiffen the parts of the body, inſtead of affording good nouriſhment; beſides, the digeſtion of theſe aliments is difficult, and render the blood ſo acrid, as to hurt the capillary veſſels.

However, an acquired habit is hard to be left off, and we find many perſons enjoy a good ſtate of health when their meat and drink are very indifferent, becauſe they are become cuſtomary, and they are apt to fall ſick when they attempt to change their manner of life; for cuſtom is a ſecond nature: all great changes ought to be brought about inſenſibly.

For this reaſon, it is good not to contract a habit of any kind; wherefore, perſons of a good conſtitution ſhould live in a various manner, and refuſe no kind of aliment; and ſhould ſometimes be in town, and ſometimes in the country; ſhould uſe much exerciſe, and ſhould even now and then exceed the exact bounds of moderation, and at other times omit a meal now and then.

Hunger ſhews the beſt time of eating, but cuſtom confines us to certain hours. Perſons who find no inconvenience from dining and ſupping every day, need not change their manner of life. In youth, wherein there is a great diſſipation, and in age, where ſtrength is wanting, and when little is eaten at a time, ſomething taken between meals is not amiſs. However, it is neceſſary to obſerve, that when the ſtomach is bad, perſons ſhould not begin to eat again till the laſt meal is digeſted.

When a perſon is greatly fatigued, and his ſpirits diſſipated, it will be neceſſary to reſt before eating. In caſes of diſtreſs and ſorrow, the aliment ſhould be very light, and ſmall in quantity, becauſe the ſtomach is weak at thoſe times.

In the ſummer, when the ſpirits and fluid parts are apt to evaporate, the aliment ſhould be light, moiſt, fluid, and eaſy of digeſtion, to repair the loſs with greater ſpeed; whereas in winter the ſtomach will admit of groſſer food.

ALIMENTARY, an epithet applied to whatever belongs to aliment or food.

ALIMENTARY *Duct*, in anatomy, a name given by ſome to the inteſtines, on account of the aliments paſſing through them.

ALIMENTARY *Duct* is alſo ſometimes uſed for the thoracic duct. See THORACIC *Duct*.

ALIMONY, in law, implies that allowance which a married woman ſues for, and is entitled to, upon any occaſional ſeparation from her huſband.

The word is Latin, *alimonia*, and properly ſignifies nouriſhment or maintenance.

ALIQUANT *Part*, in arithmetic, is that number which cannot meaſure any number exactly without ſome remainder, as 7 is an aliquant part of 16; for twice 7 wants 2 of 16, and three times 7 exceeds 16 by 5.

ALIQUOT *Part*, is that part of a number or quantity, as will exactly meaſure it without any remainder, as 2 is an aliquot part of 4, 3 of 9, 4 of 16, &c.

All the aliquot parts of any number may be found by the following rule: Divide the given number by its leaſt diviſor, and the quotient by its leaſt diviſor, until you get a quotient that cannot be farther diviſible, and you will have all the prime diviſors, or aliquot parts of that number; then, if every two, three, four, &c. of theſe diviſors be multiplied into themſelves, the products will be the ſeveral conjoined diviſors, or aliquot parts of that number. As ſuppoſe it were required to find all the aliquot parts of 60, divide it by 2, and the quotient 30 by 2, and the quotient 15 by 3, and there remains the indiviſible quotient 5. Therefore all the prime aliquot parts are 1, 2, 3, 5, and the compound ones from the multiplication of every 2, are 4, 6, 10, 15, and from that of every three, 12, 20, 30. In like manner, the aliquot parts of 360, will be found to be 1, 2, 3, 4, 5, 6, 8, 9, 10, 12, 15, 18, 20, 24, 30, 36, 40, 45, 60, 72, and 180; for all the prime aliquot parts are 1, 2, 3, 5, and thoſe from the multiplication of every 2 of theſe are 4, 6, 2, 9, 10, 15, thoſe from every 3 are 8, 12, 18, 20, 30, 45, thoſe from every 4, 24, 36, 40, 60, 90; and thoſe from every 5, 72, 120, 180.

ALKAHEST, or ALCAHEST, among chemiſts, implies an univerſal ſolvent, or that will diſſolve all bodies without exception.

The word ſeems to have been coined by Paracelſus, it being derived from no language, and was unknown before the time of that author.

Paracelſus, and the elder Van Helmont, have expreſly declared in their writings, that there is a certain fluid in nature, capable of reducing all ſublunary bodies, as well homogeneous as mixed, into their ens primum, or original matter whereof they are compoſed; or into an uniform, equable, and potable liquor, that will unite with water, and the juices of our bodies, yet retain its ſeminal virtues; and if mixed with itſelf again, will thereby be converted into pure elementary water: whence they imagined this menſtruum could at length reduce all things to water, which, itſelf, was incapable of any farther change. Such a declaration as this, ſeconded by the aſſeveration, or oath of Helmont, who religiouſly ſwears himſelf poſſeſſed of the ſecret, cauſed all the ſucceeding chemiſts ſollicitouſly to turn their thoughts and labours to find out ſuch a noble menſtruum. And the famous Mr. Boyle was ſo fond of it, that he frankly acknowledges he had rather have been maſter thereof than of the philoſopher's ſtone; as indeed, it were a thing more to be wiſhed for than the power of tranſmuting metals. That great philoſopher, however, ingenuouſly tells us, he had not the good fortune to poſſeſs it.

Now it is eaſy to conceive, that all bodies might originally grow from ſome firſt matter, which was once in a fluid form. Thus the primitive matter of gold is, perhaps, nothing more than a ponderous fluid; which, from its own nature, or a ſtrong attraction between its parts, afterwards acquires a ſolid form. The aſſertion, therefore, of Paracelſus and Helmont carries a ſhew of probability with it, when they ſay there is ſome univerſal ens, or original matter, that reſolves all bodies into their ens genitale, or the primitive ſubſtance whereof they were at firſt created. So many are the authors who have treated of this ſubject, that a library might almoſt be collected of the books written upon the alkaheſt. Weiderfelt, in his treatiſe *De Secretis Adeptorum*, has made a collection of all the opinions that have been entertained about it: but it is manifeſt from his writings, that himſelf never ſaw the thing. Pantaloon alſo, with Philalethes, Tachenius, Ludovicus, and a thouſand others, treat of the ſame ſubject. But none of them ſpeak to the purpoſe, nor declare themſelves poſſeſſed of the ſecret, except Paracelſus and Helmont, who are the original authors, and upon whoſe writings the reſt have made idle comments, or fallen into ſome whimſical conceit as to this grand ſolvent.

Many have pretended to this extraordinary menſtruum. Starkey, that excellent chemiſt, diſciple to Helmont, and friend of Mr. Boyle, was, as well as ſome others, of opinion, that it might be a preparation from putrefied urine. They were led to this by thoſe paſſages of Helmont's works, wherein he expreſſes himſelf to this effect: "Wiſdom deſpiſes thoſe who are averſe to work "upon putrefied urine." And ſpeaking of the ludus, that is the human calculus, he ſays, "Putrefied urine "diſſolves the ſtone." But he could not mean by theſe, or the like expreſſions, that putrefied urine was really the alkaheſt; becauſe urine, in what manner ſoever it be treated, always has ſomething ſulphureous or ſaline mixed therewith; and conſequently would give a foulneſs to the bodies it diſſolved, and be altered by them; which is directly oppoſite to the nature of the alkaheſt. And ſpirit of urine being an alkali, is for that reaſon expreſly declared by Helmont not to be the thing. All the other preparations from urine would likewiſe ſuffer a change. The oil of urine may be tranſmuted, and the offa alba Helmontiana is alterable by acids; characters no way comporting with the alkaheſt. The like we muſt alſo ſay of phoſphorus, which has therefore been taken for the alkaheſt, becauſe Helmont deſcribes that univerſal ſolvent as a thick, ſhining, fire-water; but this will unite with aqua-fortis, fly off, and loſe its virtue in the air, flame, and be entirely conſumed by the fire, mix with oils, and not fix mercury. Others will have it to be a preparation from ſalt of tartar; but Helmont is expreſs to the contrary. "Whoever, ſays he, "practiſes the art of phyſic, and has a concern for his "neighbour's welfare, let him learn to prepare ſuch a "ſolvent as is homogeneal, unchangeable, and able to "reduce all its objects to their original liquid matter, "whereby he will obtain the very internal eſſences of "things, and ſee their qualities and diſpoſitions; but "ſuch as cannot attain to this ſecret, ought, at leaſt, "to learn how they may render ſalt of tartar volatile; "by means whereof they may make uncommon diſſolutions." This ſalt alſo will receive a change both from acids and oils.

After all, the principal chemiſts are now perſuaded that no ſuch ſolvent ever exiſted in nature: at leaſt, that no mortal was ever poſſeſſed of the ſecret. This, indeed, ſeems ſufficiently evident from the very nature of the alkaheſt; for if it will diſſolve all bodies, it will be impoſſible to be kept in any veſſel. Van Helmont therefore cannot be believed, when he aſſerts that he had a bottle filled with alkaheſt lent him; becauſe it could not be contained in any bottle, as it would diſſolve the veſſel and be loſt.

ALKALI. See the article ALCALI.

ALKANET, in botany, the Engliſh name of a genus of plants called anchuſa. See ANCHUSA.

ALKEKENGI, winter-cherry, in botany, a low, and ſomewhat hairy palnt, with imbranched ſtalks; large heart-ſhaped acuminated leaves, ſtanding in pairs at the joints, and whitiſh bell-ſhaped flowers, riſing in the boſoms of the leaves, divided about the edges into five ſegments: the flower-cup changes into a pentagonal capſule or bladder, which, burſting, diſcovers in its bottom a red fruit like a cherry, containing numerous ſmall ſeeds with a juicy pulp. It grows wild in ſome parts of Europe, and ſpreads ſo much in our gardens as not to be eaſily extirpated. The fruit ripens about the beginning of October, and ſometimes continues to near the end of December; after which the plant dies to the ground.

Winter-cherries have an acidulous not unpleaſant taſte, mixed with, or followed by, a ſlight bitterneſs: the covering in which they are incloſed, has a ſtrong pungent bitterneſs, with which it is apt to impregnate the cherries, unleſs ſome care is taken in gathering them. As medical writers in general ſpeak of this fruit as being very bitter, we may preſume that it has been often uſed with this extraneous bitter impregnation.

Thoſe cherries are accounted powerful diuretics, operating without heat or irritation, and which may therefore be ventured on in inflammatory diſtempers: five or ſix of the cherries in ſubſtance, or an ounce of the expreſſed juice, are directed for a doſe. They are ſaid to be, in ſome places, eaten, among common people, by handfuls, and with good ſucceſs, againſt ſuppreſſions of urine, and for promoting the expulſion of mucus and gravel. Mr. Ray tells us of a gouty perſon who was cured, and kept free from returns of his diſorder, by taking eight of theſe cherries at each change of the moon; and that the operation of the medicine procured a diſcharge of extremely fetid matter by urine. The cherries may be dried ſo as to be pulverable, or the depurated juice inſpiſſated with a gentle heat to the conſiſtence of a rob, or extract, and in this ſtate preſerved for uſe. *Lewis's Hiſtory of the Materia Medica.*

ALKERMES, a compound cordial medicine, formerly much in uſe, the principal ingredient of which is kermes. See KERMES.

ALKORAN. See ALCORAN.

ALL-SAINTS, a feſtival obſerved by moſt denominations of Chriſtians, in commemoration of all the ſaints in general. It is celebrated on the firſt of November.

ALL-SOULS, a feſtival kept on the ſecond of November, in commemoration of all the faithful deceaſed.

ALLA, or ALLAH, the name of God, among the profeſſors of the Mahometan religion. It properly ſignifies the adorable Being.

The word is Arabic, and derived from *alah*, to adore.

ALLANTOIS, or ALLANTOIDES, in anatomy, a veſicle inveſting the fœtus of ſeveral animals, and containing an urinous liquor, ſuppoſed to be conveyed thither from the urachus.

The word is Greek, and compounded of αλλας, a gut, and ειδος, reſemblance.

Anatomiſts are not agreed whether the allantois has or has not any exiſtence in the human ſpecies.

ALLAY. See the article ALLOY.

ALLEGATION, in law, implies the producing inſtruments, or deeds, for proving the truth of ſomething litigated before the court.

ALLEGIANCE, in law, ſignifies the obedience which every ſubject owes to his lawful ſovereign.

The word is formed from the Latin *allegiantia*, and derived from *allego*, to admit.

Allegiance is either natural, acquired, or local.

Natural ALLEGIANCE is that which every ſubject born ought to pay immediately upon his birth.

Acquired ALLEGIANCE is that which a perſon naturalized, or made a denizen, owes to the king.

Local ALLEGIANCE is that which a perſon, on his entering the dominions of another prince, ought to pay for his protection.

Oath of ALLEGIANCE is that taken by the ſubject, and in which he acknowledges the king a temporal prince.

ALLEGORICAL, ſomething belonging to, or partaking of, the nature of an allegory. See ALLEGORY.

ALLEGORICAL *Poetry* is that wherein ſome uſeful truth is conveyed under the veil of an allegory.

Could truth engage the affections of mankind in her native and ſimple dreſs, ſhe would require no ornament, or aid, from the imagination; but her delicate light, though lively in itſelf, and clear to the moſt diſcerning, does not ſtrike the ſenſes of the multitude ſo as to ſecure their eſteem and attention; the poets therefore dreſſed her up in the manner in which they thought ſhe would appear the moſt amiable, and called in allegories and airy diſguiſes as her auxiliaries in the cauſe of virtue.

The human mind is ever enterpriſing, and in continual ſearch of ſomething new; which obtained, loſes of its value by being known, and yields but little gratification. Whatever excites curioſity will always delight, and whatever delights will ſecure to itſelf a portion of the mind, till we are urged to the purſuit of ſomething ſtill more new and more engaging: for it is a true, tho' an unfavourable obſervation, that the mind of man (ever rapacious and never ſatisfied) is always coveting what it never fully enjoys; as kings conquer nations they never mean to poſſeſs. Our pleaſures, therefore, are for the moſt part made up of expectation and novelty; and he who would inſtruct effectually, muſt give us ſomething to hope, and ſomething to excite new and pleaſing ideas in the imagination. He muſt not only enlighten and improve the underſtanding, but addreſs ſuch images to the mind as will keep it ſteady in the purſuit of truth. And this is the ſource, and indeed the buſineſs, not only of poetry, but of all the ſciences that depend upon fancy, and which, as we have already obſerved, the weakneſs of human nature has rendered neceſſary; for men are ſo ſeldom affected with the ſimple and invariable beauty of virtue, that it is of little conſequence to point out truth, unleſs we repreſent her in the moſt agreeable form, and render her ſo endearing, that ſhe may not only ſecure their attention for a time, but, by her lovelineſs, call back the mind occaſionally to a retroſpection and new contemplation of her beauties: and this is often done by a ſeaſonable uſe of the allegory, through which, as through a delightful wilderneſs variegated with flowers, lawns, ſtreams, and umbrageous trees, we are content to be led to truth, when we ſhould have little inclination to purſue the known and beaten track that afforded us no ſuch entertainment.

The power which allegorical poetry has over the mind may be felt by reading the poets that have written in this manner; but eſpecially Spenſer, who had a bold and boundleſs fancy, and was a moſt admirable painter, or imager, of the virtues and vices. His deſcriptions are, indeed, rich and luxuriant; but if we miſtake not, it is principally owing to his juſt and beautiful allegories (the creatures of his own fancy) that he has been deemed the father of Engliſh poetry, and led more young minds into the ſtudy of this bewitching art than any other poet. Cowley, Milton, and Dryden, are ſaid to have caught their firſt flame from him, and the laſt has been more frequent and full in the praiſe of Spenſer than of any other poet. But enough has been ſaid on the excellency and uſe of the allegory; it is neceſſary now that we explain what we mean by allegorical poetry, and lay down ſuch rules as ought to be obſerved in thoſe compoſitions.

An allegory is a fable, or ſtory, in which, under the diſguiſe of imaginary perſons or things, ſome real action, or inſtructive moral, is conveyed to the mind. Every allegory, therefore, has two ſenſes, the one literal, and the other myſtical; the firſt has been aptly enough compared to a dream, or viſion, of which the laſt is the true meaning or interpretation.

From this definition of allegorical poetry the reader will perceive that it gives great latitude to genius, and affords ſuch a boundleſs ſcope for invention, that the poet is allowed to ſoar beyond all creation; to give life and action to virtues, vices, paſſions, diſeaſes, and natural and moral qualities; to raiſe floating iſlands, inchanted palaces, caſtles, &c. and to people them with the creatures of his own imagination.

> The poet's eye, in a fine frenzy rolling,
> Doth glance from heav'n to earth, from earth to heav'n;
> And, as imagination bodies forth
> The forms of things unknown, the poet's pen
> Turns them to ſhape, and gives to airy nothing
> A local habitation and a name. SHAKESPEARE.

But whatever is thus raiſed by the magic of his mind, muſt be viſionary and typical, and the myſtical ſenſe appear obvious to the reader, and inculcate ſome moral or uſeful leſſon in life; otherwiſe the whole will be deemed rather the effects of a diſtempered brain, than the productions of real wit and genius. The poet, like Jaſon, may ſail to parts unexplored, but will meet with no applauſe if he returns without a golden fleece; for theſe romantic reveries would be unpardonable, but for the myſtical meaning and moral that is thus artfully and agreeably conveyed with them; and on which account only, the allegory is indulged with a greater liberty than any other ſort of writing.

The ancients conſidered this ſort of allegory as the moſt eſſential part of poetry, and undoubtedly it is; for the power of raiſing images of things not in being giving them a ſort of life and action, and preſenting them, as it were, before the eyes, was thought to have ſomething in it like creation: but then, in ſuch compoſitions, they always expected to find a meaning couched under them of conſequence, and we may reaſonably conclude that the allegories of their poets would never have been handed down to us, had they been deficient in this reſpect.

As the fable is the part immediately offered to the reader's conſideration, and intended as an agreeable vehicle to convey the moral, it ought to be bold, lively, and ſurpriſing, that it may excite curioſity, and ſupport attention; for, if the fable be ſpiritleſs and barren of invention, the attention will be diſengaged, and the moral, however uſeful and important in itſelf, will be little regarded.

There muſt likewiſe be a juſtneſs and propriety in the fable, that is, it muſt be cloſely connected with the ſubject on which it is employed; for, notwithſtanding the boundleſs compaſs allowed the imagination in theſe writings, nothing abſurd, or uſeleſs, is to be introduced. In epic poetry ſome things may, perhaps, be admitted for no other reaſon but to ſurpriſe, and to raiſe what is called the wonderful, which is as neceſſary to the epic as the probable; but in allegories, however wild and extravagant the fable and the perſons introduced, each muſt correſpond with the ſubject they are applied to, and, like the members of a well-written ſimile, bear a due proportion and relation to each other: for we are to conſider that the allegory is a ſort of extended or rather multiplied ſimile, and therefore, like that, ſhould never loſe the ſubject it is intended to illuſtrate: whence it will appear, that the genius and fancy are here inſufficient without the aid of taſte and judgment; theſe firſt, indeed, may produce a multitude of ornaments, a wilderneſs of ſweets, but the laſt muſt be employed to accommodate them to reaſon, and to arrange them ſo as to produce pleaſure and profit.

But it is not ſufficient that the fable be correſpondent with the ſubject, and have the properties above deſcribed; for it muſt alſo be conſiſtent with itſelf. The poet may invent what ſtory he pleaſes, and form any imaginary beings that his fancy ſhall ſuggeſt; but here, as in dramatic writings, when perſons are once introduced, they muſt be ſupported to the end, and all ſpeak and act in character; for, notwithſtanding the general licence here allowed, ſome order muſt be obſerved, and, however wild and extravagant the characters, they ſhould not be abſurd. Add to this, that the whole muſt be clear and intelligible; for the "fable, as Mr. Hughes obſerves, being deſigned only to cloath and adorn the moral, but not to hide it, ſhould reſemble the draperies we admire in ſome of the ancient ſtatues, in which the folds are not too many nor too thick, but ſo judiciouſly ordered, that the ſhape and beauty of the limbs may be ſeen through them."

ALLEGORIST, one who writes in, or has recourſe to, allegories.

ALLEGORY, a figurative diſcourſe, in which ſomething elſe is intended than what is contained in the words literally taken.

The word is Greek, *αλληγορια*, and compounded of *αλλο*, otherwiſe, and *αγορεω*, to relate.

ALLEGRO, in muſic, an Italian word, ſignifying that the part is to be played in a briſk, gay, and ſprightly manner.

ALLERION, in heraldry, a ſort of eagle, without beak or feet, having nothing perfect but the wings.

ALLEVEURE, a ſmall braſs Swediſh coin, worth about 2 ¼ *d.* Engliſh.

ALLEY, in gardening, a ſtrait parallel walk, bounded on both ſides with trees, ſhrubs, &c. and uſually covered with gravel or turf.

It is diſtinguiſhed from a path, by being broad enough for two to walk a-breaſt.

Covered ALLEY is that over which the branches of the trees on each ſide meeting each other, form a ſhade.

ALLEY *in ziczac*, is that formed by ſeveral angles, in order to render it more ſolitary and obſcure.

ALLEY *of compartment*, that which divides the ſquare of a parterre.

ALLIANCE, in the civil and canon law, implies the relation between two perſons, or two families, contracted by marriage.

Alliance is alſo uſed to ſignify a treaty entered into by ſovereign princes or ſtates, for their mutual ſafety or defence.

Defenſive **Alliance** is that whereby the contracting parties engage to ſtand by and aſſiſt each other againſt any power that ſhall attack either.

Offenſive **Alliance** implies an agreement between powers, whereby they engage themſelves to attack jointly ſome other prince or ſtate.

ALLIARIA, *Jack by the Hedge*, or *Sauce all alone*, in botany, the name of a plant, with a ſlender, white, ligneous root, with a garlick ſmell, from whence proceed ſtalks to the height of about two feet, round, ſlender, hairy, ſtriated, and ſolid. The leaves at firſt are round, like thoſe of ground-ivy, but much bigger, and afterwards acquire a ſort of a point; are crenated on the edges; ſmooth, and of a pale green colour, with ſomewhat of the ſmell and taſte of garlick. They are placed in no regular order; and at the top are many flowers, conſiſting of four white petals, from whoſe flower-cup ariſes a piſtil that turns to a fruit, or membranaceous round pod, with a partition in the middle, to which two imbricated valves adhere on each ſide, divided into two cells, full of oblong, roundiſh, black ſeeds.

It is common in hedges and ſhady waſte places, and flowers in May and June. It is good in cold ſcurvies, and in conſtitutions that abound with acids. Outwardly, the juice is good in putrid and ſordid ulcers. If the herb has been dried for a day in the ſhade, and then bruiſed in a mortar, and the juice expreſſed, it will keep in bottles for ſeveral years, with oil at the top. *Brookes's Natural Hiſtory.*

ALLIGATION, in arithmetic, is the method of reſolving queſtions relating to the mixture of commodities, and their value and effects, when united in a compoſition.

The word is formed of Latin, *alligare*, to tie together; perhaps from a ſort of vincula, or circular ligatures, ordinarily uſed to connect the ſeveral numbers together.

Alligation is of two kinds, *medial* and *alternate*.

Alligation *Medial* is when, from the ſeveral quantities and rates of divers ſimples given, we diſcover the mean rate of a mixture compounded out of them.

To anſwer queſtions of this ſort, the ſum of all the quantities propoſed to be mixed, and alſo the ſum of their particular rates, muſt be found. Then the proportion will be,

As the ſum of all the quantities is to the ſum of all their rates, ſo is any part of the mixture to the mean rate or price of that part.

Examp. A goldſmith has three ſorts of gold, of the reſpective values of 3*l.* 18*s*; 3*l.* 12*s*; and 3*l.* 6*s.* per ounce; if 7 ounces of the firſt ſort, 9 ounces of the ſecond, and 12 of the third, be mixed together, it is propoſed to find the value of a ſingle ounce of this compoſition.

The queſtion prepared as above directed will ſtand,

$$\begin{array}{lllllll} & & \text{£.} & s. & & & s. \\ \text{Thus,} & \left\{\begin{array}{l} 7 \text{ oz. at} \\ 9 \text{ oz. at} \\ 12 \text{ oz. at} \end{array}\right. & \begin{array}{l} 3 \\ 3 \\ 3 \end{array} & \begin{array}{l} 18 \\ 12 \\ - \end{array} & \begin{array}{l} \text{per ounce} \\ - \ - \\ - \ - \end{array} & \begin{array}{l} - \ - \ - \\ - \ - \ - \\ - \ - \ - \end{array} & \begin{array}{r} 546 \\ 648 \\ 792 \end{array} \end{array}$$

28 = their ſum. And their total value = 1986

Then 28 oz. : 1986*s.* :: 1 oz. 70*s.* $\frac{13}{14}$ = 3*l.* 10*s.* 11*d.* $\frac{1}{7}$, the anſwer required.

Alligation *Alternate*, is when the rates or qualities of divers ſimples are given, and the quantity of each is required, neceſſary to make a mixture of the given rate or quality.

Alligation *Alternate* ſhews the due proportion of ſeveral ingredients, and counterchanges the places of ſuch exceſſes or differences as ariſe between the mean price and the extremes, aſcribing that to the greater extreme, which proceeds from the leſſer, and contrarily.

To reſolve queſtions relating to alligation alternate, the rule is to ſet down all the particular rates, with their mean rate; then take the ſeveral differences between the mean rate, and the particular rates, ſetting down thoſe differences alternately; this done, add all the differences into one ſum: then the proportion will be,

As the ſum of all the differences is to the ſum of all the quantities given; ſo is every particular difference to its particular quantity required.

Examp. A grocer would make a mixture of 144 pounds of ſugar, which would be worth 12 pence per pound, and that mixture to conſiſt of four ſorts of ſugar at the reſpective prices of 6, 10, 15, and 17 pence per pound: it is required to find how much of each ſort of ſugar is neceſſary to that compoſition?

$$\text{Mean price } 12 \left\{\begin{array}{c} 6 \\ 15 \\ 10 \\ 17 \end{array}\right\} \begin{array}{c} 3 \\ 6 \\ 5 \\ \underline{2} \end{array}$$

16 the ſum of the differences.

$$\text{Then} \left\{\begin{array}{l} 16 : 144 :: 3 : 27 \text{ the pounds of } 6d. \\ 16 : 144 :: 6 : 54 \text{ the pounds of } 15d. \\ 16 : 144 :: 5 : 45 \text{ the pounds of } 10d. \\ 16 : 144 :: 2 : 18 \text{ the pounds of } 17d. \end{array}\right\} \text{per pound.}$$

Note, the work of theſe proportions may be greatly ſhortened, by dividing the ſecond number by the firſt, and multiplying that quotient by the reſpective third numbers; for theſe products will anſwer the queſtion.

In order to give a general demonſtration of the above rule for reſolving queſtions relating to alligation alternate, let m repreſent the mean rate of the intended compoſition $m-a$, $m+b$, $m-c$, $m+d$, &c. the ſeveral rates of the component parts, S the ſum total of the compound. Now, by writing down the ſeveral rates together with their mean rate, as in the foregoing example, and taking the alternate differences, we ſhall have,

$$m \left\{\begin{array}{l} m-a \\ m+b \\ m-c \\ m+d \\ \text{\&c. \&c.} \end{array}\right\} \begin{array}{l} b \\ a \\ d \\ c \\ \text{\&c.} \end{array}$$

Put $b+a+d+c$, &c. $= s$, then, according to the above rule, it will be

$$\left.\begin{array}{l} s : \mathrm{S} :: b : \frac{b \times \mathrm{S}}{s} \\ s : \mathrm{S} :: a : \frac{a \times \mathrm{S}}{s} \\ s : \mathrm{S} :: d : \frac{d \times \mathrm{S}}{s} \\ s : \mathrm{S} :: c : \frac{c \times \mathrm{S}}{s} \\ \text{\&c. \&c.} \end{array}\right\} \begin{array}{c} \text{the required quantity of that part} \\ \text{whoſe mean rate is} \end{array} \left\{\begin{array}{l} m-a \\ m+b \\ m-c \\ m+d \\ \text{\&c.} \end{array}\right.$$

Now it is very evident that the ſum of theſe quantities, viz. $\frac{b \times \mathrm{S}}{s} + \frac{a \times \mathrm{S}}{s} + \frac{d \times \mathrm{S}}{s} + \frac{c \times \mathrm{S}}{s}$, &c. is equal to S; for, as they have one common denominator, viz. s, which is equal to $b+a+d+c$, &c. and the ſum of the numerators equal to $\overline{b+a+d+c, \text{\&c.}} \times \mathrm{S}$, it follows that the ſum of the ſaid quantities will be expreſſed by $\frac{s \times \mathrm{S}}{s}$ or S. It only now remains to ſhew that the ſum of the products ariſing by multiplying theſe quantities into their correſponding rates, will be equal to the ſum total of the compound multiplied into the mean rate. Let the rate $m-a$ be multiplied by its correſponding quantity $\frac{b \times \mathrm{S}}{s}$, the product is $\frac{bm-ab}{s} \times \mathrm{S}$: in the ſame manner, by multiplying the remaining quantities by their adjacent rates, and taking the total of all the products, we ſhall have $\frac{bm-ab}{s} \times \mathrm{S} + \frac{am+ab}{s} \times \mathrm{S} + \frac{dm-dc}{s} \times \mathrm{S} + \frac{cm+cd}{s} \times \mathrm{S}$, &c. which, being properly contracted, becomes $\frac{bm+am+dm+cm}{s}$ &c. $\times \mathrm{S}$, or by reſtoring the value of s, $\frac{b+a+d+c, \text{\&c.}}{b+a+d+c, \text{\&c.}} \times m\,s$, that is $m\,\mathrm{S}$. Q. E. D.

Corol. The quantities $\frac{b \times \mathrm{S}}{s}$, $\frac{a \times \mathrm{S}}{s}$, $\frac{d \times \mathrm{S}}{s}$, are in a direct ratio of the alternate differences.

Hence we get the following rule for the ſolution of queſtions appertaining to *alligation partial*, ſo called when the particular rates of all the ingredients propoſed to be mixed, the mean rate of the whole mixture, and any one of the quantities to be mixed are given, to find how much of each of the other ingredients is requiſite to compoſe the mixture.

The rule, Set down all the particular rates, with their mean rate, and find their differences, as in *Alligation alternate*, without having any regard to the quantity given.—Then the proportion will be,

As the quantity found by the differences of the ſame name with the quantity given, is to the given quantity; ſo is any of the other quantities found by the differences, to the quantity of its name.

ALLIGATOR, in natural hiſtory, an amphibious creature common in South-America, ſuppoſed by ſome authors to be the ſame with the crocodile found in Aſia and Africa. Its head is long, and ſlender towards the extremity, gradually forming a ſnout like that of a hog. Both the upper and lower jaws have a row of very ſtrong and pointed teeth.

Theſe creatures abound in the river of Guaiaquil in South-America, and when tired of fiſhing leave the water to baſk in the ſun, where they appear more like logs of half rotten wood thrown aſhore by the current, than living creatures; but upon perceiving any veſſels near them, they immediately plunge into the water. Some of them are of ſo monſtrous a ſize, as to exceed five yards in length. During the time they lie baſking on the ſhore, they keep their huge mouths wide open, till filled with muſchetos, flies, and other inſects, when they ſuddenly ſhut their jaws, and ſwallow their prey. Its whole body is covered with ſcales impenetrable to a muſket-ball, unleſs it happens to hit them in the belly near the fore-legs, the only part vulnerable.

The alligator is an oviparous creature. The female makes a large hole in the ſand near the brink of a river, and there depoſits her eggs, which are nearly equal to thoſe of an oſtrich, and as white as thoſe of a hen, but much more ſolid. She generally lays about an hundred, continuing in the ſame place till they are all depoſited, which is about a day or two. She then covers them with the ſand, and the better to conceal them, rolls herſelf not only over her precious depoſitum, but to a conſiderable diſtance. After this precaution ſhe returns to the water, till natural inſtinct inform her, that it is time to deliver her young from their confinement; when ſhe comes to the ſpot, followed by the male, and tearing up the ſand, begins breaking the eggs, but ſo carefully, that ſcarce a ſingle one is injured; and a whole ſwarm of little alligators are ſeen crawling about. The female then takes them on her neck and back, in order to remove them into the water; but the watchful gallinazos make uſe of this opportunity to deprive her of ſome; and even the male alligator, which, indeed, comes for no other end, devours what he can, till the female has reached the water with the few remaining; for all thoſe which either fall from her back, or do not ſwim, ſhe herſelf eats; ſo that of ſuch a formidable brood happily not more than four or five eſcape.

The gallinazos, a large bird, common in South-America, are their moſt inveterate enemies, or rather extremely fond of their eggs, in finding which they make uſe of uncommon addreſs. Theſe birds often make it their whole buſineſs to watch the females during the ſummer, the ſeaſon when they lay their eggs, the ſands on the ſides of the rivers not being then covered with water. The gallinazo perches in ſome tree, where it conceals itſelf among the branches, and there ſilently watching the female alligator till ſhe has laid all her eggs, retires pleaſed that ſhe has concealed them beyond diſcovery. But ſhe is no ſooner under the water than the gallinazo darts down on the repoſitory, and with its beak, claws, and wings, tears up the ſand, and devours the eggs, leaving only the ſhells. This banquet would, indeed, richly reward its long patience, did not a multitude of gallinazos, from all parts, join the fortunate diſcoverer, and ſhare in the ſpoil.

Theſe alligators are the greateſt deſtroyers of the fiſh, it being their moſt ſafe and general food; nor are they wanting in addreſs to ſatisfy their deſires: eight or ten, as it were by compact, drawn up at the mouth of a river or creek, whilſt others of the ſame corps go a conſiderable diſtance up the river and chaſe the fiſh downwards, by which means none of any bigneſs eſcape them. The alligators, being unable to eat under water, on ſeizing a fiſh, raiſe their heads above the ſurface, and by degrees draw the fiſh from their jaws, and chew it for deglutition. After ſatisfying their appetite, they retire to reſt on the banks of the river.

When they cannot find fiſh to appeaſe their hunger, they betake themſelves to the meadows bordering on the banks of the river, and devour calves and colts; and in order to be more ſecure in ſeizing their prey, take the opportunity of the night, that they may ſurpriſe them in their ſleep; and it is obſerved, that thoſe alligators which have once taſted fleſh, become ſo fond of it, as never to take up with fiſh but in caſes of neceſſity. There are even too many melancholy inſtances of their devouring the human ſpecies, eſpecially children, who, from the inattention natural to their age, have been without doors after it is dark; and though at no great diſtance, theſe voracious animals have dared to attack them, and having once ſeized the child with their mouth, to make ſure of their prey againſt that aſſiſtance which the cries of the victim never fail to bring, haſten into the water, where they immediately drown it, and then return to the ſurface and devour it at leiſure.

The inhabitants of thoſe places where they abound, are very induſtrious in catching and deſtroying them. Their uſual method is by a caſonate, or piece of hard wood ſharpened at both ends, and baited with the lungs of ſome animal. This caſonate they faſten to a thong, the end of which is ſecured on the ſhore. The alligator, on ſeeing the lungs floating on the water, ſnaps at the bait, and thus both points of wood enter his jaws in ſuch a manner, that he can neither ſhut nor open his mouth. He is then dragged aſhore, where he violently endeavours to reſcue himſelf, while the Indians bait him like a bull, knowing that the greateſt damage he can do is to throw down ſuch as for want of care or agility do not keep out of his reach.

ALLIUM, garlick, in botany, the name of a plant, with a bulbous root, conſiſting of ſeveral membranes, of a whitiſh colour, mixed with a purpliſh caſt. The leaves are oblong, not fiſtulous as in onions, but like graſs, and the flowers conſiſt of ſix whitiſh leaves, with a piſtil in the middle, which turns into a roundiſh fruit of the ſize of a pea, and of a purpliſh colour without, but the pulp within is whitiſh. It is divided into three cells, full of roundiſh and blackiſh ſeeds. Garlick is proper to warm and ſtimulate the ſolids, and to diſſolve the groſs clammy fluids, whence it is good in cold conſtitutions, and in moiſt aſthmas, as well as all defluxions on the breaſt. It has been found very ſerviceable in the dropſy, for it will ſometimes cure it without any other medicine. It may be given alone, or in a decoction, made into a ſyrup; but it muſt be avoided in all inflammatory diſpoſitions and hot diſeaſes. It may be eaſily propagated in gardens, by planting the cloves, or ſmall bulbs, in Auguſt or September, about four or five inches from each other. In the middle of June the leaves ſhould be tied in knots, to prevent their running to ſeed, and then the bulb will be greatly enlarged. Towards the end of July the leaves will begin to wither, and then the root ſhould be taken out of the ground, and hanged up in a dry room. *Brookes's Natural Hiſtory.*

ALLOCATION, an allowance made upon account in the Exchequer.

ALLOCATIONE *Facienda*, a writ for allowing to an accountant ſuch ſums of money as he has lawfully expended in his office; directed to the lord-treaſurer, and barons of the Exchequer.

ALLOCATO *Comitatu*, a new writ of exigent allowed, before any other county-court, held on the former not being fully ſerved or complied with.

ALLODIAL, an epithet applied to an inheritance held without paying any acknowledgement to either lord or ſuperior.

The word is formed from the Saxon *a* privative, and *leof*, lord; *q. d.* held without a ſuperior.

Allodial lands are what we term free lands, which a perſon enjoys without paying any fine, rent, or ſervice.

ALLODIUM, free lands, or ſuch as are the abſolute property of their owner, without his being obliged to pay any acknowledgement whatſoever.

ALLOM. See the article ALUM.

ALLOY, or ALLAY, a proportion of a baſer metal with one that is finer.

All gold coin has an alloy of ſilver, and ſilver coin an alloy of copper. A pound weight of ſtandard gold, by the preſent ſtandard of the mint, is two and twenty carats fine, and two carats alloy; and a pound weight of ſtandard ſilver conſiſts of eleven ounces two penny weights of fine ſilver, and eighteen penny weights of alloy. And in proportion as gold or ſilver has more or leſs alloy than that abovementioned, it is ſaid to be coarſer or finer than the ſtandard.

ALLUMINOR, a perſon who colours or paints upon paper or parchment.

The word is derived from the French, *allumer*, to lighten.

ALLUSION, in rhetoric, a figure by which ſomething is applied to, or underſtood of another, on account of ſome ſimilitude between them.

ALLUVION, among civilians, denotes the gradual increaſe of land along the ſea-ſhore, or on the banks of rivers.

ALMACANTARS, in aſtronomy, are leſſer circles of the ſphere parallel to the horizon, imagined to paſs through all the points of the meridian.

The word is formed of the Arabic *almacantharat*.

The almacantars are the ſame thing with regard to the azimuths and horizon, that the parallels of latitude are with regard to the equator. See AZIMUTH.

The almacantars ſerve to ſhew the height of the ſun and ſtars; and are deſcribed on ſome quadrants, &c. being alſo called parallels of altitude. See PARALLEL *of altitude.*

ALMACANTARS-*Staff*, an inſtrument uſually made of pear tree or box, having an arch of fifteen degrees, uſed to take obſervations of the ſun, about the time of its riſing and ſetting, in order to find the amplitude, and conſequently the variation of the compaſs.

ALMAGEST, the name of a book compoſed by Ptolemy, containing a variety of geometrical problems, and a great number of aſtronomical obſervations made by the antients.

The original title of this work was *συνταξις μαγιϛη*, the great conſtruction or collection; but the Arabians, who tranſlated it into their language, prefixed to the laſt word *magiſte*, the Arabic particle *al*, calling it *almagiſte*; whence the preſent name.

There are alſo other collections called by the ſame name. Thus Riccioli publiſhed a ſyſtem of aſtronomy, which he called the *New Almageſt*; and Plunkenet, a book which he ſtiled *Almageſtum Botanicum*.

ALMANAC, a table containing a calendar of days and months, the riſing and ſetting of the ſun, the age of the moon, the eclipſes of both luminaries, &c.

Authors are divided with regard to the etymology of the word, ſome deriving it from the Arabic particle *al*, and *manah*, to count; ſome from *almanah*, new-year's gifts; becauſe the Arabian aſtrologers uſed, at the beginning of the year, to make preſents of their ephemerides; and others from the Teutonic *almaen-achte*, obſervations on all the months. Mr. Johnſon derives it from the Arabic particle *al*, and the Greek *μην*, a month.

Hereſy of ALMARIC, a tenet broached in France by one Almaric, in the year 1209. It conſiſted in affirming, that every Chriſtian was actually a member of Chriſt; and that without this faith no one could be ſaved.

His followers went farther, and affirmed, that the power of the Father laſted only during the continuance of the Moſaic law; that the coming of Chriſt introduced a new law; that at the end of this began the reign of the Holy Ghoſt; and that now confeſſion and the ſacraments were at an end, and that every one is to be ſaved by the internal operations of the Holy Spirit alone, without any external act of religion.

ALMENE, in commerce, a weight of two pounds, uſed in weighing ſaffron in ſeveral parts of the continent of the Eaſt-Indies.

ALMOND-TREE, *Amygdalus*, in botany, the name of a diſtinct genus of trees, with roſaceous flowers, and an oblong ſtony fruit, in which is incloſed a kernel of the ſame ſhape.

Almond-trees have a beautiful effect in a garden, while they continue in bloom, and are accordingly cultivated in this country more for the ſake of their flowers than their fruit: though the latter are alſo well worth attending to, and may, with proper care, in a well-ſheltered warm ſituation, be produced very good in England.

Theſe trees are propagated by inoculating a bud of them with a plum or a peach ſtock, or into a ſtock of their own kind, in the month of July. The next ſpring when the buds ſhoot is the time to train them up, either for ſtandards or half-ſtandards, as the cultivator chuſes: though the uſual method is to bud them at the height intended for their ſtems. In the ſecond year after budding, they will be fit to tranſplant into the places they are to remain. The beſt ſeaſon for doing this is in October, as ſoon as their leaves begin to decay, if they are to ſtand in dry ground; but if they are to be removed into a wet ſoil, February is a far more preferable time. It is likewiſe to be obſerved, that plum-ſtocks will always prove the beſt for the latter, and almond, or peach-ſtocks, for the former ſituation.

The bloſſoms of theſe trees often appear in February, when the ſpring is forward: but if froſt comes on while they are out, their beauty is of ſhort duration, for they are ſoon deſtroyed, and produce very little fruit. On the other hand, if theſe trees do not flower till late in March, they ſeldom fail of bearing plenty of almonds, many of which will be very ſweet, and fit for the table when green; but they will not keep long.

ALMONDS, the fruit of the almond-tree.

There are two kinds of almonds, ſweet and bitter. The greateſt quantity of both ſorts are produced in Syria, Barbary, Turkey, Spain, Italy, the iſland Cyprus, and France. The German ſhops are ſupplied chiefly from Provence and Valencia. In England, three ſorts of almonds are diſtinguiſhed, ſmall Barbary almonds, long Jordan almonds, and ſhort, broad, Spaniſh or Valencia almonds.

Sweet almonds conſiſt chiefly of expreſſible oil, and a fine farinaceous earth; the oil is ſo plentiful, and ſo looſely intermixed with the other principles, that a part of it may be ſqueezed out with the fingers. The medical uſes of ſweet almonds are, to ſoften and obtund acrimony, and to render reſinous ſubſtances ſoluble in water, and in the animal fluids. The reſins of jalap, ſcammony, and others, triturated with almonds, diſſolve in water into an emulſion, and in this form operate effectually, without producing the violent gripes and other dangerous conſequences, which they never fail to do when given by themſelves.

Bitter almonds yield alſo an oil to the preſs, not bitter like the almonds themſelves, but as taſteleſs as that of the ſweet kind, all the bitter matter remaining in the cake left after the expreſſion. Several experiments have been made for determining in what principle the bitterneſs reſides; but they have not anſwered ſo perfectly as could be wiſhed. The almond-cake was diſtilled both with pure water, and with water and ſalt, and with highly rectified ſpirit of wine. The diſtilled waters were ſcarcely bitter, but ſmelt a little of the almond, and had a conſiderable pungency; the diſtilled ſpirit diſcovered ſcarcely any pungency or bitterneſs, and differed very little, in ſmell or taſte, from the pure ſpirit employed: the greateſt part of the bitterneſs, in all diſtillations, was left behind, and continued in the inſpiſſated extracts.

Bitter almonds are poiſonous to animals, particularly to birds. In the human body, they act as reſolvents and aperients. Sweetened with ſugar, or made into an emulſion, they are conſidered as diuretic, and an anthelmintic; but ſeem to be too dangerous a medicine to be given with ſafety, there being inſtances of cordial ſpirits flavoured with bitter almonds proving poiſonous to the human ſpecies.

ALMOND *Furnace*, a ſmall furnace, in which the refiners of ſilver from lead melt the ſlags of the litharge left after this operation, and by the help of charcoal reduce them again into lead.

ALMONDS, in anatomy, a name ſometimes given to two glands, generally called the tonſils. See TONSILS.

ALMONDS, among lapidaries, ſignify pieces of rock-cryſtal, uſed in adorning branch-candleſticks, &c. on account of the reſemblance they bear to the fruit of that name.

ALMONER, an officer appointed to diſtribute alms to the poor.

Lord ALMONER, or *Lord-high* ALMONER *of England* is an eccleſiaſtical officer, generally a biſhop, who has the forfeiture of all deodands, and the goods of felos de ſe, which he is to diſtribute among the poor.

He has alſo, by virtue of an ancient cuſtom, the power of giving the firſt diſh from the king's table to whatever poor perſon he pleaſes, or, inſtead of it, an alms in money.

ALMUCANTARS. See ALMACANTARS.

ALNAGE, or AULNAGE, the meaſuring of woollen manufactures with an ell.

It was at firſt intended as a proof of the goodneſs of the commodity, and accordingly a ſeal was invented as a mark that the commodity was made according to the ſtatute; but, it being now poſſible to purchaſe theſe ſeals, they are affixed, whenever the vender pleaſes, to all cloths indiſcriminately, to the great prejudice of our woollen manufactures.

ALNAGER, a public officer, whoſe duty it is to examine into the aſſize of all woollen cloth, fix ſeals upon the various pieces, and collect the alnage-duty for the king.

ALNUS, in botany, the alder-tree. See ALDER-TREE.

ALOOF, in navigation, keep aloof, (commonly called keep the luff) is the command given by the pilot or officer to the helmſman, to direct the ſhip's courſe nearer the wind, or nearer that point of the compaſs which the wind blows from. This phraſe probably regards the dangers of a lee-ſhore, from which the pilot might order the helmſman to "keep aloof."

ALOE, in botany, a genus of plants, with a liliaceous flower, conſiſting of one tubular leaf, divided into ſix deep ſegments at the edge. In ſome ſpecies of this genus, the cup, and in others the piſtil, finally becomes a fruit, or ſeed-veſſel, of an oblong cylindric form divided into three cells, containing flat ſemicircular ſeeds.

The ſoil in which theſe plants thrive beſt is on half freſh light earth from a common (and if the turf is taken with it, and rotted, it is much better), the reſt ſhould be white ſea-ſand, and ſifted lime-rubbiſh, of each of theſe two a fourth part; mix theſe together ſix or eight months at leaſt before it is uſed, obſerving to turn it over often in this time.

The firſt ſpecies of aloes is very hardy, in reſpect to cold; and has, in mild winters, endured abroad, being planted in a very dry ſoil, and under a ſouth wall; but, as they are liable to be killed in hard froſts, they generally are kept in pots or tubs in a common green-houſe, with oranges, myrtles, &c. but muſt have very little moiſture in winter. Moſt of the other ſorts are better preſerved in an airy glaſs-caſe, in which there is a ſtove to make a little fire in very bad weather, to dry and warm the air in foggy, cold, or wet weather, and to prevent the froſt from entering the houſe.

The fifth, ſixth, ſeventh, eighteenth, thirty-fourth, and thirty-fifth ſorts, require a greater ſhare of heat to preſerve them in winter, and ſhould be ſet in a good ſtove, and kept nearly to the degree of heat marked (upon Mr. Fowler's Botanical Thermometers) temperate. Indeed, moſt of the other ſorts may be kept in the ſame temperature of heat in winter; but then you muſt obſerve, that the greater the heat is in winter, in which you keep them, the more water they will require: and, if they are well managed in this heat, they will grow very much in winter; therefore, great care muſt be taken in the ſevere cold, that it doth not enter the houſe, nor that the heat be at that time leſſened; as alſo how you begin to give them air in the ſpring; for the extreme parts of the plants will be rendered very tender, by their growing freely in winter; and the leaſt check to their growth, at that ſeaſon, is very often their deſtruction.

Moſt of the African ſorts of aloes produce flowers with us annually, when grown to a ſufficient ſize, which is generally the ſecond, and ſeldom more than the third year, after planting from off-ſets; but the American aloes (which, for the moſt part, produce their flower-ſtems immediately from the center of the plant) ſeldom flower till they are of a conſiderable age, and this but once during the life of the plant; for when the flower-ſtem begins to ſhoot from the middle of the plant (which, for the moſt part, is of a large ſize, and grows to a great height), it draws all the moiſture and nouriſhment from the leaves; ſo that, as that advances, the leaves decay; and, when the flowers are fully blown, ſcarce any of the leaves remain alive; but, whenever this happens, the old root ſends forth a numerous quantity of off-ſets for increaſe; and it is not till this time, that ſome of theſe ſorts can be increaſed, eſpecially the ſecond, third, fourth, fifth, ſixth, and ſeventh ſorts, which never produce any young plants until they flower; at which time the flower-ſtem of the ſeventh ſort is beſet with ſmall heads from bottom to top, which, being taken off, and planted, will grow as well as ſuckers from the roots.

This aloe, which with us ſeldom makes a very large plant, hath yet produced flower-ſtems of a conſiderable ſize, and fifteen feet in height. The flowers are little leſs than thoſe of the large ſort. I cannot here forbear taking notice of a vulgar error relating to the large American aloe; which is, that it never flowers till it is an hundred years old; but this is a miſtake; ſince we have had ſeveral of them flower in England, ſome of which were known not to exceed fifty years old, and others, which flowered many years ago, cannot be ſuppoſed to have been in England ſo long as to arrive at that age, ſince they were thought too tender for our climate at that time, when green-houſes were not known; as may be ſeen by looking into Gerrard's and Parkinſon's Herbals.

Thoſe who are deſirous of having this ſort of aloe flower, may, by giving the plants large tubs for their roots to ſpread, greatly promote their growth; and, in proportion to the growing of the plants, their flowering is haſtened; for the bud being formed in the center of the plants, when the number of leaves which enfold it are thrown off, the ſtem will advance: ſo that in Spain and Portugal, where the plants grow faſt, they produce flowers in eighteen or twenty years; and in the Weſt-Indies, where they grow faſter, in ſeven or eight.

The African aloes, for the moſt part, afford plenty of ſuckers, by which they are increaſed; but thoſe few that do not may be moſt of them propagated, by taking off ſome of the under leaves, laying them to dry for a week or ten days, as was directed for the off-ſets; then plant them in the ſame ſoil as was directed for them, putting that part of the leaf which did adhere to the old plant about an inch, or an inch and a half (according to the ſize of the leaf) into the earth, giving them a little water to ſettle the earth about them: then plunge the pots into a moderate hot bed, obſerving to ſcreen them from the violence of the ſun, and give them gentle refreſhings with water. The beſt ſeaſon for this is in June, that they may puſh out heads before winter. *Miller's Dict.*

ALOES, in the materia medica, a bitter, gummy, reſinous, inſpiſſated juice; prepared from the leaves of the above ſpecies of plants. There are three different ſorts of aloes found in the ſhops, diſtinguiſhed by the names of *ſocotorine*, *hepatic*, and *caballine*.

ALOE *Socotorina*. Socotorine aloes are brought from the iſland Socotora, in the Indian ocean, wrapt in ſkins; and obtained from the *aloe ſocotorina anguſtifolia ſpinoſa flore pupureo*. This ſort of aloes is of a bright ſurface, and in ſome degree pellucid, in the lump; of a yellowiſh red colour, with a purpliſh caſt: when reduced into powder, of a golden colour. It is hard and friable in the winter; ſomewhat pliable in the ſummer, and ſoftens betwixt the fingers. Its bitter taſte is accompanied with an aromatic flavour, but not ſufficient to prevent its being diſagreeable: the ſmell is not very unpleaſant, and ſomewhat reſembles that of myrrh.

ALOE *Hepatica*. Hepatic, Barbadoes, or common aloes, are uſually brought from Barbadoes; the beſt ſort in large gourd ſhells; an inferior kind in pots; and a ſtill worſe in caſks; and extracted from the *aloe dioſcordis et aliorum*, of Sloane. This is darker-coloured than the foregoing, and not ſo clear or bright. It is generally drier and more compact; though ſometimes, eſpecially the caſk ſort, quite ſoft and clammy. Its ſmell is much ſtronger and more diſagreeable; the taſte intenſely bitter and nauſeous, with little or nothing of the aromatic flavour of the ſoccotorine.

Aloe *Caballina*. Caballine, or horſe aloes, are prepared, probably, from the *aloe guineenſis caballina vulgari ſimilis ſed tota maculata*, and not, as is generally ſuppoſed, from the fœces of the hepatic; the difference not being in purity, but in quality. It is eaſily diſtinguiſhed from both the foregoing by its ſtrong rank ſmell: in other reſpects it agrees pretty much with the hepatic; and is, not unfrequently, ſold in its place. Sometimes it is prepared ſo pure and bright as ſcarce to be diſtinguiſhable by the eye, even from the ſocotorine; but its offenſive ſmell readily betrays it: and if this alſo ſhould be diſſipated by art, its wanting the aromatic flavour of the finer aloes will be a ſufficient criterion.

Aloes is a ſtimulating cathartic bitter: taken in ſufficient doſes to purge effectually, as two ſcruples or a dram, it occaſions commonly a great irritation about the anus, and ſometimes a diſcharge of blood. In ſmaller doſes, or ten or twelve grains, repeated once or twice a day, it not only evacuates the firſt paſſages, but attenuates and diſſolves viſcid humours in the remoter parts; warms the habit, quickens the circulation, and promotes the menſtrual and hæmorrhoidal fluxes: its continued uſe renders the blood ſenſibly more fluid, as appears on venæſection. For a time, in theſe ſmall doſes, it does not act by ſtool; but at length it produces a gentle looſeneſs, of longer continuance than that occaſioned by moſt other purgatives: hence its utility in habitual coſtiveneſs. This ſtimulating cathartic is particularly adapted to perſons of a phlegmatic temperament and ſedentary life, to cachectic indiſpoſitions, and oppreſſions of the ſtomach by viſcid crudities contracted from irregularity: in dry bilious habits it is often injurious, immoderately heating the blood, or inflaming the bowels.

This bitter juice is accounted deſtructive to worms, (or to the matter which favours their production) whether taken internally, or applied in plaiſters to the umbilical region. It is powerfully antiſeptic; and commonly made an ingredient in tinctures and balſams for cleanſing and healing wounds or putrid ſores.

Aloes conſiſts of a reſinous matter, and a large proportion of a ſubſtance called gum. By boiling in water, in the proportion, for inſtance, of four ounces to a quart, it nearly all diſſolves, except the impurities, into a dark-coloured liquor, which, on ſtanding in the cold for a night, depoſites the reſin to the bottom, the gummy part continuing diſſolved. From this ſolution (poured off from the precipitated reſin, and, if any feculencies appear in it, paſſed through a ſtrainer) the gum may be recovered in a ſolid form by evaporation. The coarſer ſorts of aloes may be purified from their feculencies, without any ſeparation of the gummy and reſinous parts, by ſtraining the ſolution whilſt hot, and ſetting it directly to evaporate, without ſuffering it to ſettle.

The hepatic aloes is found to contain more reſin and leſs gum than the ſoecotorine; and this than the caballine. Twelve ounces of caballine aloes yielded two of reſin; the ſame quantity of ſocotorine three; of hepatic almoſt four; of gummy extract, the caballine yielded nine ounces; the ſocotorine ſomewhat leſs than nine; the hepatic eight. The watery ſolution of the gummy part of the ſocotorine, after the ſeparation of the reſin, appeared of a bright brown colour, with a caſt of red; that of the caballine, deep reddiſh brown; of the hepatic, browniſh yellow, without any tendency to redneſs.

The reſins of all the ſorts, purified by ſolution in ſpirit of wine, (for in their ſettling from the watery decoction of the aloes, the impurities of the juice ſubſide along with them) have little ſmell: that obtained from the ſocotorine has ſcarcely any perceptible taſte, that of the hepatic a ſlight bitteriſh reliſh, and that of the caballine a little more of the aloetic flavour. The gummy extracts alſo are leſs diſagreeable than the crude aloes; the extract of the ſocotorine has a very little ſmell, and is in taſte ſcarcely unpleaſant; that of the hepatic is in ſmell ſomewhat ſtronger, but ſeems to taſte rather leſs ungrateful than the extract of the ſoecotorine; the gum of the caballine retains a conſiderable ſhare of the peculiar rank ſmell of this kind of aloes, but its taſte is not much more unpleaſant than that of the extracts made from the other two.

The purgative virtue of aloes, contrary to that of moſt of the other cathartic vegetables, reſides chiefly in the gummy part; the reſin, though taken in conſiderable doſes, (whether divided by teſtaceous powders, or diſſolved in ſpirit of wine) having little or no cathartic power. Socotorine aloes, which contains more gum than the hepatic, purges more, and with greater irritation: the former therefore is to be preferred where a ſtimulus is required, as for promoting or exciting the menſtrual flux; whilſt the latter is better fitted for a common purge. The vulnerary and balſamic virtues, on the other hand, reſide principally in the reſin; and hence the hepatic, which is more reſinous than the ſocotorine, is found to be more ſerviceable in external applications. The caballine aloes, on account of its offenſive ſmell, is very rarely made uſe of, at leaſt under its own name, either internally or externally.

The purgative aloetic gum diſſolves, not only in watery, but likewiſe in ſpirituous menſtrua; and even more readily in proof ſpirit and in rectified ſpirit, than in water or wine. When powdered aloes is macerated, or digeſted in a gentle warmth, with water, with wine, or with vinous ſpirits largely diluted, the powder ſoftens, and becomes tenacious, and the ſolution goes on exceeding ſlowly: hence, in making tinctures or ſolutions of aloes in theſe kind of menſtrua, it is of advantage to mix with the powder ſome clean dry ſand, which, by keeping it divided, promotes the diſſolution. With rectified and proof ſpirits, the aloes does not cohere, but continues powdery till diſſolved.

Aloes is ſometimes taken by itſelf, ſometimes mixed with ſaponaceous medicines, warmed with aromatics, acuated with pungent materials, combined with the deobſtruent gums, &c. Many of theſe kinds of compoſitions have been received as officinals: a pill, for example, compoſed of equal parts of aloes and ſoap, with a proper quantity of thin honey: a powder, of eight parts of aloes, with two of canella alba, or with one of virginian ſnake-root, and one of ginger: a tincture, made by digeſting five ounces of theſe powders in five or ſix pints of mountain wine: pills of four parts of aloes, two of myrrh, and two or one of ſaffron, made up with ſyrup of ſaffron, or of orange peel: vinous and ſpirituous tinctures of the aloes, with different proportions of the myrrh and ſaffron, &c.

Among different aromatic materials made trial of, cloves ſeemed the beſt adapted for alleviating the offenſiveneſs of the aloes: the committee appointed by the London college for reforming their Pharmacopœia, made choice of canella alba, on account of its not rendering the medicine ſo hot as the neceſſary quantity of the clove itſelf would do, and yet having ſo much of the clove flavour, as to cover the aloes in a ſufficient degree: ſome commend the caſia caryophyllata, or clove bark, as having more of the clove flavour than canella alba, and yet not being very hot. Where volatile ſpirits are to be joined, a ſolution of the aloes, in dulcified ſpirit of ſal ammoniac, or in ſpirit of ſal ammoniac made with quicklime, are very elegant preparations, and require little aſſiſtance from aromatics to render them ſupportable to the palate; the offenſiveneſs of the aloes being greatly abated by the ſpirit, and the pungency of the ſpirit ſheathed by the aloes; the ſpirit of ſal ammoniac made fixed with alkaline ſalt, does not diſſolve near ſo much of the aloes as the two abovementioned. *Lewis's Hiſtory of the Materia Medica.*

Aloes *Wood.* See Lignum *Aloes.*

ALOETICS, a general name for all medicines, whoſe baſis or principal ingredient is aloes.

ALOGIANS, in eccleſiaſtical hiſtory, a ſect of ancient heretics, who denied that Jeſus Chriſt is the logos, or eternal word; and therefore they rejected the goſpel of St. John as a ſpurious production.

The word is Greek, and compounded of α, priv. and λόγος, the word.

ALOPECIA, in medicine, implies a falling off of the hair, occaſioned either by a defect of nouriſhment, or a bad ſtate of the humours.

ALP, a name given to the bullfinch, in ſeveral parts of England. See BULLFINCH.

ALPHA, the name of the firſt letter of the Greek alphabet, anſwering to our A.

As a numeral it ſtands for one, or the firſt of any thing; hence alpha and omega, being the firſt and laſt letters in the Greek alphabet, are uſed to ſignify the eternity of God.

ALPHABET, the natural or cuſtomary ſeries of the ſeveral letters of a language.

The word is formed from *alpha*, and *beta*, the firſt and ſecond letters of the Greek alphabet.

The number of letters is different in the alphabets of different languages. The Engliſh alphabet contains 24 letters, to which if we add *j* and *v* conſonant, the ſum will be 26; the French 23; the Hebrew, Chaldee, Syriac, and Samaritan, 22 each; the Arabic 28; the Perſian 31; the Turkiſh 33; the Georgian 36; the Coptic 32; the Muſcovite 43; the Greek 24; the Latin 22; the Sclavonic 27; the Dutch 26; the Spaniſh 27; the Italian 20; the Ethiopic and Tartarian, each 202, the Indians of Bengal 21; the Barameſe 19. The Chineſe have, properly ſpeaking, no alphabet, except we call their whole language by that name: their letters are words, or rather hieroglyphics, amounting to about 80,000.

ALPHABET is alſo uſed for a cypher, or table of the uſual letters of the alphabet, with the correſpondent ſecret characters, and other blank ſymbols intended to render the writing more difficult to be decyphered.

ALPHABET, among merchants, a kind of index, with the twenty-four letters in their natural order, in which are ſet down the names of thoſe who have open accounts, referring to the folios of the ledger.

ALPHABETICAL, ſomething belonging to, or placed in the order of, the alphabet.

ALPHETA, in aſtronomy, the name of a fixed ſtar in the northern crown, and generally called lucida coronæ. See the article *Lucida* CORONÆ.

ALPHONSIN, in ſurgery, an inſtrument for extracting bullets out of gun-ſhot wounds.

This inſtrument derives its name from the inventor Alphonſus Ferrier, a phyſician of Naples. It conſiſts of three branches, which are cloſed by a ring. When cloſed and introduced into the wound, the operator draws back the ring towards the handle, upon which the branches opening take hold of the ball; and then the ring is puſhed from the haft, by which means the branches graſp the ball ſo firmly as to extract it from the wound.

ALPHONSINE tables, aſtronomical tables calculated by order of Alphonſus king of Caſtile, in the conſtruction of which that prince is ſuppoſed to have contributed his own labour.

ALPHOS, among phyſicians, a diſeaſe of the ſkin, otherwiſe called *vitiligo*, when that membrane is ſprinkled, or, as it were, covered with white ſpots. Several authors conſider it as a ſymptom of the leproſy. See the article LEPROSY.

The word is Greek, αλφος, a radix in that language, and ſignifies white.

ALRAMECH, in aſtronomy, the name of a ſtar of the firſt magnitude, generally called Arcturus. See ARCTURUS.

ALSINASTRUM, in botany, a genus of plants reſembling the alſine, or chickweed.

ALSINE, chickweed, in botany, a ſmall, creeping, juicy herb; annual, yet common in all times of the year in ſhady cultivated ground.

This herb was formerly employed in cataplaſms againſt external inflammations; and its expreſſed juice, a decoction, given alſo internally, as an aperient, antiſcorbutic, antiphlogiſtic, and as a reſtorative (that is, perhaps, for abating hectic fits) in atrophies and conſumptions. Nor do the virtues aſcribed to it appear to be wholly without foundation: experiment diſcovers, that it is not deſtitute of active matter, though this matter is ſo far divided and diluted in the herb, as ſcarcely to manifeſt itſelf till ſeparated from the groſſer parts.

The freſh leaves have an herbaceous ſomewhat ſaline taſte, without any remarkable ſmell: in diſtillation, with water or with ſpirit, they give over nothing. On expreſſion, they yield a large quantity of green-coloured turbid juice; which difficultly depoſits its fœces upon ſtanding, but immediately parts with them on being heated to ebullition, and, being now paſſed through a ſtrainer, looks clear and reddiſh. The depurated juice, inſpiſſated to the conſiſtence of an extract, diſcovers to the taſte a cool penetrating ſaline pungency, which quickly goes off, leaving a ſlight auſterity in the mouth. *Lewis's Hiſtory of the Materia Medica.*

ALT, in muſic, a term applied to the high notes in the ſcale. See GAMUT.

ALTAR, a place upon which ſacrifices were anciently offered to ſome deity.

As ſacrifices offered up to God are as ancient as the world, altars are of no leſs antiquity. The Scripture in ſome places ſpeaks of altars erected by the patriarchs, without deſcribing the form or matter of them. The altar which Jacob ſet up at Bethel, was nothing but a ſtone which had ſerved him for a pillow. Gideon ſacrificed upon nothing better than a ſtone which was before his houſe. The firſt altars which God commanded Moſes to raiſe to him muſt have been of earth, or rough ſtones; and the Lord declared to him, that if any uſe were made of iron in them, they would be impure. The altar of burnt-offerings which he cauſed ſome time after to be made, was a kind of trunk of Shittim-wood, hollow, and covered over with plates of braſs.

The altar which Moſes enjoined Joſhua to build upon mount Ebal, was to be of unpoliſhed ſtones; and it is very probable, that thoſe which were built afterwards by Samuel, Saul, and David, were of the ſame ſtructure. The altar which Solomon erected in the temple was of braſs, but filled, as is believed, with rough ſtones. It was twenty cubits long, twenty wide, and ten in height. Laſtly, that which was built at Jeruſalem by Zerubbabel, and other Jews who returned from Babylon, was only of rough ſtones: nor was that which the Maccabees rebuilt any better. Joſephus ſays, that the altar which in his time was in the temple was of rough ſtones, fifteen cubits high, forty long, and as many in width.

ALTAR *of Incenſe.* This was a ſmall table of ſhittim-wood, covered with plates of gold, of one cubit in length, another in width, and two in height. At the four corners of it were four kinds of horns, and all round a little border or crown over it. Every morning and evening, the prieſt in waiting for that week, and appointed by lot for this office, offered incenſe of a particular compoſition upon this altar; and to this end, entered with the ſmoaking cenſer filled with fire from the altar of burnt-offerings in the Holy, where this altar was fixed over-againſt the ſhew-bread table. This was the altar which was hidden by Jeremiah before the captivity. The prieſt, having placed the cenſer on it, retired out of the Holy. See Plate IV. *fig.* 5.

Altar, or table, for the ſhew-bread was a ſmall table of ſhittim-wood, covered with plates of gold, having a little border round it, adorned with ſculpture. It was two cubits long, one cubit wide, and one and a half in height. It was placed in the Holy. Upon this table, every ſabbath-day, were put twelve loaves with ſalt and incenſe.

ALTAR *of Burnt-offerings.* This was a kind of coffer of ſhittim-wood, covered with braſs plates. It was five cubits ſquare, and three in height. Moſes placed it to the eaſt, before the entrance of the tabernacle, in the open air, that ſo the fire, which was to be kept perpetually upon it, and the ſmoak ariſing from the ſacrifices which were burnt there, might not ſpoil the inſide of the tabernacle. At the four corners of the altar there was an appearance as it were of four horns, covered with the ſame metal as the reſt of the altar. Within the depth or hollow of it was a grate of braſs, on which the fire was made; through this fell the aſhes in proportion as they increaſed upon the altar, and were received below within a pan which was placed under it. At the four corners of this grate were four rings, and

four chains, which kept it up at the four horns of the altar abovementioned. As this altar was portable, Moſes had rings made and faſtened to the ſides of it, into which were put ſtaves of ſhittim-wood, overlaid with braſs, by the help whereof it was removed from place to place.

Such was the altar of burnt-offerings belonging to the tabernacle erected by Moſes in the wilderneſs: but in Solomon's temple it was much larger. This was a kind of cube, twenty cubits long, as many wide, and ten in height. It was covered with thick plates of braſs, and filled with rough ſtones; on the eaſt ſide there was an eaſy aſcent leading up to it. When the Jews returned from the captivity of Babylon, they rebuilt the altar of burnt-offerings after the model of Solomon's; but after both the temple and altar had been prophaned by the orders of Antiochus Epiphanes, this altar was demoliſhed, and the ſtones of it were laid up in ſome part of the temple which was unpolluted, till a prophet ſhould be raiſed up by God, who ſhould come and declare the uſe for which they were reſerved. Herod the Great having made a new temple, built an altar of burnt-offerings like that which had been there before; but Joſephus ſays, that the aſcent up to it was on the ſouth-ſide.

The altar of burnt-offerings, according to the rabbins, was a large maſs all built of rough and unpoliſhed ſtones, the baſis whereof was thirty-two cubits, or forty-eight feet ſquare. From thence the altar roſe one cubit, or a foot and a half, then there was a diminiſhing of one cubit in thickneſs; from thence the altar being only thirty cubits ſquare, roſe five cubits, and received a new diminution or in-benching of two cubits, and conſequently was reduced to twenty-eight cubits ſquare. From thence again it roſe three cubits, and grew two cubits ſmaller. Laſtly, it roſe again one cubit, and ſo being in all twenty-four cubits, or thirty-ſix foot ſquare, it formed the hearth on which the ſacrifices were burnt, and the perpetual fire kept up. See Plate IV. *fig.* 4.

The diminution of two cubits abovementioned, which was about the middle of the altar, ſerved as a paſſage for the prieſts to go and come about the altar, to attend the fire, and place the ſacrifices on it. This altar was compoſed of large plates of maſſy braſs, whence it is called the braſen altar. It is believed, that the altar was all filled with rough ſtones or earth, according to what is ſaid in Exodus; "An altar of earth thou ſhalt make unto me, and ſhalt ſacrifice thereon thy burnt-offerings, and thy peace-offerings—and if thou wilt make me an altar of ſtone, thou ſhalt not build it with hewn ſtone, for if thou lift up thy tool upon it, thou haſt polluted it." At the four corners of the altar, on the laſt diminution or in-benching, were four ſmall pillars of a cubit ſquare, and in the form of a perfect cube. Theſe are the horns of the altar, ſo often mentioned in Scripture; they were hollow, that part of the blood of the ſacrifices might be poured into them.

The aſcent to the altar was by an inſenſible riſe on the ſouth-ſide, and was called kibbeſh; it was thirty-two cubits in length, and ſixteen in breadth, and landed upon the upper benching-in, near the hearth or top of the altar; for to go up to the altar by ſteps was by the law forbidden. The prieſts might go round about the altar, and perform their offices very conveniently upon the two in-benchings which we have deſcribed; namely, that of the middle, which was a cubit, and that above it, which was likewiſe a cubit broad; for it would have been very uneaſy for them to have walked barefoot on the hearth, which was always heated by the fire that was continually burning there.

With regard to the heathens, they made their altars at firſt only of turf; but afterwards they were made of ſtone, of marble, of wood, and even of horn, as that of Apollo in the iſland of Delos. The figure of them, as well as the materials, was different; ſome were round, others ſquare, others oval: they were always turned towards the eaſt, and ſtood lower than the ſtatues of the gods, which were placed upon baſes above the altar, which was generally adorned with leaves and flowers; thoſe of Apollo with laurel; thoſe of Hercules with poplar; Jupiter's with oak; Venus's with myrtle; and thoſe of Minerva with olive. The altars were uſually conſecrated with oil, which was poured upon them.

A ſecond uſe of altars was to ſerve as a place of refuge, or ſanctuary, to all thoſe who fled to them, whatever crimes they had committed. Romulus was the firſt who appointed theſe places of refuge in the temples, that by this means he might people his new city: and the privileges of theſe ſanctuaries came to ſo great a height, that, at Rome, and in the cities of Greece, the temples were filled with debtors, fugitive ſlaves, and criminals, in defiance of the civil power, which could not force them from the altars.

The height of altars differed, according to the different gods to whom they were conſecrated: for the Θεοι ουρανιοι, or Celeſtial Gods, had their altars raiſed to a very great height above the ground; inſomuch that Pauſanias tells us, that the altar of Olympian Jupiter was almoſt twenty-two feet high. To the terreſtrial gods and heroes, they ſacrificed upon altars almoſt cloſe to the ground; and they dug a hole in the earth for thoſe of the infernal gods.

Before temples were in uſe, altars were erected, ſometimes in groves, ſometimes in the highways, and ſometimes on the tops of mountains: and it was cuſtomary to engrave upon them the name, a proper enſign, and character of the deity to whom they were dedicated. Thus St. Paul obſerved on an altar at Athens this inſcription, Αγνωϛω Θεῳ, To the unknown God.

ALTAR is alſo uſed to denote the communion table in the reformed churches.

ALTAR, in aſtronomy. See ARA.

ALTARAGE, the profits ariſing to a prieſt on account of the altar.

ALTERANTS, in medicine. See the article ALTERATIVES.

ALTERATE, in muſic and geometry. See SESQUIALTERATE.

ALTERATIVES, or ALTERATIVE medicines, in the healing art, are ſuch medicines as correct the bad qualities of the animal fluids, without occaſioning any ſenſible evacuation.

ALTERNATE, in a general ſenſe, ſignifies a term applied to ſuch perſons or things, as ſucceed each other by turns.

ALTERNATE, in botany, implies ſuch a diſpoſition of the leaves of a plant, that the firſt on one ſide of a branch ſtands higher than the firſt on the other ſide; the ſecond the ſame, and ſo on to the top.

ALTERNATE, in heraldry, is ſaid with regard to the ſituation of the quarters. Thus the firſt and fourth quarters, and the ſecond and third, are uſually of the ſame nature, and are thence called alternate quarters.

ALTERNATE *Angles*, in geometry, are thoſe acute or obtuſe angles which are oppoſite to each other, and formed by a right line cutting two parallel right lines. Thus if A B (plate X. *fig.* 5.) be parallel to C D, and the line G H cuts them in I and K, then are the angles A I K, D K I, and B I K, I K C, alternate angles, by 18 Euc. 1. and are always equal.

Alligation ALTERNATE. See ALLIGATION.

ALTERNATE *Ratio*, or *Proportion*, is where the antecedent of the one ratio is to its conſequent, as the antecedent of another to its conſequent; the very ſame ratio, in this caſe, holding alternately in reſpect of the antecedents to each other, and the conſequents to each other.

Thus, if $A:B::C:D$; then alternately $A:C::B:D$. See PROPORTION.

ALTERNATION properly ſignifies a ſucceſſion by turns.

ALTERNATIONS, in arithmetic, is a term ſometimes uſed to expreſs the various changes or alterations of order in any number of things propoſed.

This is alſo called permutation, &c. and is eaſily found by a continual multiplication of all the numbers, beginning at unity. Thus, if it be required to know how many changes or alternations can be rung on ſix bells, multiply the numbers 1, 2, 3, 4, 5, 6, continually one into another, and the laſt product gives the number of changes, in this caſe, 720. See the inveſtigation of this rule under the word CHANGE.

ALTERNATIVE, in a general ſenſe, implies nearly the ſame as alternate. See ALTERNATE.

ALTHÆA, *Marſhmallow*, in the materia medica, a ſoft hoary plant, with oblong undivided leaves, and pale fleſh-coloured monopetalous flowers, cut deeply into five ſections, ſet in a double cup, the outermoſt of which is divided into nine parts, the inner into five: the fruit conſiſts of a number of capſules, ſet in form of a flat diſk, containing each a ſingle ſeed: the roots are long and ſlender, with ſeveral fibres of a pale yellowiſh colour on the outſide, and white within. It grows wild in marſhes and other moiſt places, though frequently cultivated in gardens. It is perennial, and flowers from June to near the end of ſummer.

All the parts of althæa abound with a glutinous juice, of ſcarcely any ſmell or particular taſte. The dry roots, boiled in water, give out near half their weight of gummy matter; which, on evaporating the aqueous fluid, forms an unctuous, flavourleſs, yellowiſh mucilage. The leaves afford ſcarcely one-fourth their weight, and the flowers and ſeeds ſtill leſs; though the two latter have been looked upon by ſome as the moſt mucilaginous, and accordingly preſcribed in leſs quantity than the other parts of the plant.

Of all the mucilaginous vegetables, marſhmallow-root is, among us, of the moſt general uſe, for obtunding and incraſſating acrimonious thin fluids, in tickling coughs from defluxions on the ſauces and lungs, in hoarſeneſs, eroſions of the ſtomach and inteſtines, difficulty and heat of urine, and for lubricating and relaxing the paſſages in nephritic and calculous complaints.

The root is ſometimes given in powder, from a ſcruple to a dram or two, either by itſelf, or in conjunction with other materials of ſimilar intention, as gum tragacanth, ſtarch, &c. It is rather too bulky, however, for this form; and may, in moſt caſes, be taken to better advantage in that of an infuſion or decoction, ſweetened with a little liquorice: an ounce of the dry root is ſufficient for a quart or three pints of water, a larger proportion rendering the liquor diſagreeably ſlimy. A ſyrup, made by boiling a pound of the freſh roots in a gallon of water till half the liquor is waſted, preſſing out the decoction, and after ſettling for a night, boiling it down with four pounds of fine ſugar till the weight of the whole is ſix pounds, is kept in the ſhops, and employed occaſionally in ſome diſorders of the breaſt, and for ſweetening emollient decoctions in nephritic caſes. *Lewis's Hiſtory of the Materia Medica.*

ALTIMETRY, the art of meaſuring altitudes or heights, whether acceſſible or inacceſſible. See ALTITUDE.

The word is compounded of the Latin, *altus*, high, and the Greek, μετρεω, to meaſure.

ALTITUDE, *Altitudo*, in geometry, the third dimenſion of body, conſidered with regard to its elevation above the ground; called alſo height or depth.

The word is derived from the Latin, *altus*, high.

ALTITUDE *of a Figure*, is the diſtance of its vertex from its baſe, or the length of a perpendicular let fall from the vertex to the baſe. Thus KL (plate IX. *fig.* 3.) being taken for the baſe of the triangle KML, the perpendicular MP, let fall from the vertex M upon the baſe KL, will be the altitude of the triangle.

Triangles of equal baſes and altitudes are equal, and parallelograms, whoſe baſes and altitudes are equal to thoſe of triangles, are juſt double thereof.

ALTITUDE, in optics, is uſually conſidered as the angle ſubtended between a line drawn from the eye, parallel to the horizon, and a viſual ray emitted from an object to the eye.

If, through the two extremes of an object, S and T (plate IX. *fig.* 7.) two parallels, TV and SQ, be drawn, the angle TVS, intercepted between a ray paſſing through the vertex S, and terminating the ſhadow thereof in V, makes with the right line TV, what is called, by ſome writers, the altitude of the luminary.

ALTITUDE *of the Eye*, in perſpective, is a right line let fall from the eye perpendicular to the geometrical plane.

ALTITUDE, in aſtronomy, is the diſtance of the ſun or ſtar from the horizon. This altitude is meaſured by an arch of a vertical circle, intercepted between the point where the ſun or ſtar then is, and the horizon.

Apparent ALTITUDE of any heavenly object, is the arch of a vertical circle intercepted between the ſenſible horizon and the center of the object.

True ALTITUDE is the arch of a vertical circle comprehended between the center of the object and the rational horizon.

The true altitudes of the ſun and planets differ but very little from their apparent altitudes; becauſe of their great diſtances from the center of the earth, and the ſmallneſs of the earth's ſemi-diameter, when compared thereto: but the diſtance between the true and apparent altitude of the moon is very conſiderable, it ſometimes amounting to upwards of 50 minutes.

Meridian ALTITUDE *of the Sun*, *Planet*, or *Star*, is an arch of the meridian intercepted between the horizon and the center of the object. For the method of obſerving the meridian altitude of an heavenly object, ſee MERIDIAN *Altitude*, and OBSERVATION.

ALTITUDE *of the Pole* is the height of the pole above the horizon, or an arch of the meridian intercepted between the pole and the horizon.

The altitude of the pole is always equal to the latitude of the place, and the diſtance of the pole from the zenith of the place, is always the complement of the latitude thereof.

ALTITUDE *of the Equinoctial* is the elevation of the equinoctial above the horizon, and is always equal to the complement of the latitude, or the complement of the altitude of the pole.

ALTITUDE *of the nonageſimal Degree* is the altitude of the nonageſimal degree, counted from the point at which it riſes; or it is the complement of the diſtance of the 90th degree of the ecliptic, reckoned from the orient, or eaſt point. See NONAGESIMAL.

ALTITUDE *of Motion*, a term made uſe of by Dr. Wallis, to expreſs the meaſure of any motion computed according to the line of direction of the moving force.

ALTITUDE *of the Earth's Shadow*. See ECLIPSE *of the Moon.*

ALTITUDE *of the Moon's Shadow*. See ECLIPSE *of the Sun.*

Refraction of ALTITUDE is an arch of a vertical circle, as S*s* (plate IX. *fig.* 5.) whereby the altitude SE, of a ſtar, or other body, is increaſed by means of the refraction.

Parallax of ALTITUDE is the difference CB (plate IX. *fig.* 8.) between the true and apparent place of a ſtar; or the difference BC, between the true diſtance of a ſtar AB, and the obſerved diſtance AC, from the zenith A.

The parallax diminiſhes the altitude of a ſtar, or increaſes its diſtance from the zenith. To find the parallax of altitude, ſee PARALLAX.

Quadrant of ALTITUDE. See the article QUADRANT.

ALTITUDE, in coſmography, is the perpendicular height of an object, or its diſtance from the horizon, upwards.

The altitudes of objects, ſituated on the ſurface of the earth, are either acceſſible or inacceſſible.

Acceſſible ALTITUDE *of an Object*, is that whoſe baſe you can have acceſs to, i. e. meaſure the neareſt diſtance between your ſtation and the foot of the object on the ground.

To take an acceſſible ALTITUDE, let C (plate IX. *fig.* 1.) repreſent a tower ſtanding upon level ground, whoſe height is required; with a chain or ſtaff of a known length, meaſure the diſtance between your ſtation at E and D, the foot of the tower, which ſuppoſe equal to 160 feet; then, holding the quadrant in a horizontal poſition, look through the ſights at the tower, and where the viſual ray terminates make a mark, as at A, which will ſhew the height of the eye above D, the bottom of the tower; then elevate the inſtrument till C, the top of the tower, is ſeen through the ſights. Now it is plain that the triangle BAC is formed by theſe three lines, viz. BA the diſtance of the obſerver's eye from the tower, AC the height of the tower above his eye, and BC a line drawn from his eye to the top of the tower. In this triangle the angle A is a right one by the ſuppoſition the angle B is found by the quadrant, which ſuppoſe 70°, and the meaſure of one ſide, B A, is known, viz. 160 feet; whence A C may be eaſily found: for if B A be made radius, then A C will be the tangent of the angle C B A. Therefore, as radius : A B :: tang. ang. A B C : A C = 440; and conſequently, if A D, the height of the obſerver's eye from the ground, be added, you will have the whole height of the tower C D.

An acceſſible ALTITUDE may alſo be meaſured geometrically, without the help of the quadrant, in the following manner. Suppoſe it were required to find the height of the tree C D, (plate IX. *fig.* 2.) plant a ſtaff, as E B, of a known length perpendicularly in the ground; then, lying proſtrate on your face, move yourſelf forwards or backwards till the top of the ſtaff E be in a right line with that of the tree at D: meaſure the diſtance from the eye at A to the ſtaff at B, and alſo from A to the foot of the tree at C; then, becauſe the triangles A B E and A C D are ſimilar, it will be, as A B : A C :: B E : C D, the height of the tree required.

Inacceſſible ALTITUDE *of an Object*, is that when the foot or bottom thereof cannot be approached by reaſon of ſome impediment.

To take an inacceſſible ALTITUDE; let A B (plate IX. *fig.* 6.) be a tower, whoſe height is required: to do this make choice of two ſtations, D and C, in the ſame right line with B; then meaſure the ſtationary diſtance D C, and with a quadrant, or other proper inſtrument, take the angles D and C, as before in acceſſible altitude. Now the two viſual lines D A and C A, together with the diſtance D C, form an oblique-angled triangle, wherein there are given the three angles D, A C D, and D A C; for the difference of the obſerved angles is equal to the angle C A D. Therefore ſay, As the ſine of the angle C A D is to C D, ſo is the ſine of the angle A D C to A C. Then, radius : A C :: ſine < A C B : A B, the height of the tower required.

To find the inacceſſible ALTITUDE *of an Object ſtanding upon a Hill.* Lt A K (plate IX. *fig.* 4.) be a tower upon a hill, whoſe height is required to be found on the plane at the foot of the hill: firſt make choice of two ſtations, as D, C, in a right line with the object, and at D take the angle A D B, then meaſure the diſtance D C, and at C take the angles A C B and K C B. Now, in the oblique triangle A D C, we have the baſe D C and the angles given, to find A C, (as in the foregoing propoſition) which being obtained, we ſhall have radius : A C :: ſine < B A C : B C, whence A B may be found; laſtly, as radius : tang. of the obſerved angle K C B :: B C : B K, which ſubtracted from A B, leaves A K the height required.

The method of taking conſiderable terreſtrial altitudes, of which thoſe of mountains are the greateſt, by means of the barometer, is very eaſy and expeditious. This is done by obſerving, on the top of the mountain, how much the mercury has fell below what it was at the foot of the mountain. See BAROMETER.

ALTO and BASSO, in law, denotes the abſolute ſubmiſſion of all differences high and low to ſome arbitrator.

ALTOM, a name given in ſeveral parts of the Turkiſh dominions to what the Europeans call a ſequin. See SEQUIN.

ALTO-RELIEVO. See the article RELIEVO.

ALTO-REPIENO, in muſic, the tenor of the grand chorus, which ſings or plays only now and then in ſome particular places.

ALTUS, in muſic. See COUNTER-TENOR.

ALVARISTS, in eccleſiaſtical hiſtory, a branch of the Thomiſts, ſo called from Alvares their leader, who aſſerted the doctrine of ſufficient grace, inſtead of the efficacious grace of the ancient Thomiſts. See THOMISTS.

ALUCO, in natural hiſtory, a name by which ſome authors call the common white owl. See OWL.

ALUDE, a kind of coloured ſheep's leather dreſſed with the wool on.

ALUDELS, in chemiſtry, are earthen pots without bottoms, inſerted into each other, and uſed in ſublimations. See the article SUBLIMATION.

The firſt aludel is fitted to a pot, containing the matter to be ſublimed, and placed in the furnace; the ſecond aludel is adjuſted to the former; and in this manner any number of aludels, requiſite in the operation, are placed on each other, and the upper one fitted to a blind head, where the flowers that aſcend higheſt are retained.

ALVEARIUM, in anatomy, the hollow of the auricle, or external ear.

The word is Latin, and derived from *alveus*, a channel, or cavity.

ALVEOLUS, in natural hiſtory, ſignifies one of thoſe waxen cells which compoſe the combs in bee-hives.

Theſe cells ſerve both for ſtore-houſes, wherein the honey and wax for future uſe are depoſited, and alſo for niduſes to defend the embryo bees, while hatching. See BEE.

Perhaps there is not in nature a more remarkable inſtance of inſtinct, than in the conſtruction of theſe cells, it having been found that the form in which they are conſtructed, requires the leaſt wax to contain the ſame quantity of honey. See the article COMB.

ALVEOLUS, in anatomy, the ſocket-like cavity in the jaw wherein each of the teeth are ſet.

ALVEOLUS, in botany, a name given to each of the cells containing the ſeeds of certain plants.

ALUM, *Alumen*, in natural hiſtory, a ſemi-tranſparent, auſtere, ſtyptic ſalt, compoſed of the vitriolic acid, and a certain earth, found in all the argillaceous foſſils hitherto examined.

The greateſt quantities of this ſalt are artificially produced from different kinds of minerals, whoſe nature and compoſition are little known.

The reddiſh Roman alum is prepared from a reddiſh ſtone found at the bottom of the hill Tolfa, near Civita Vecchia, in the Eccleſiaſtical State. In Sweden and ſome parts of Bohemia, alum is made from pyritæ and other ores; in England, at Altſattel, and ſundry other places, from bituminous minerals of the pit-coal kind; at Solfatara near Naples, from a whitiſh earth; in Miſnia, from a blackiſh one; at Leowenberg near Freyenwalde, from a reddiſh one; and from different minerals at Saalfeld, Reichenbach, Leuſersdorff, Suſersdorff, Eliard, Schwentzel, Duben, &c. There are waters impregnated with alum, though few if any that leave a perfect alum on bare evaporation.

The pureſt and moſt perfect alum ore is the reddiſh ſtone of Tolfa: this is ſaid to yield alum without any additional matter, though not without artificial management: the alum obtained from it is tinctured with the reddiſh colour of the ſtone. In its natural ſtate it gives no marks of alum; and, if expoſed to the air, it continues a hard inſipid ſtone. Calcined or roaſted, and then laid for a time in the air, it becomes by degrees aluminous, and gives out its alum on being boiled in water. This is the alum which the Italians call *alum di rocca*, alum made from a ſtone or rock; among us, the name *alumen rupeum*, or rock alum, is often applied to the larger cryſtalline maſſes, whatever ſubject they have been prepared from.

The aluminous pyritæ and bitumens require no calcination, unleſs they greatly abound with ſulphur. Theſe minerals, at firſt taken out of the earth, are compact, and often bright and glittering: they have no manner of taſte, and diſcover no mark of their holding any thing ſaline; the vitriolic acid being as yet blended with an inflammable matter, by which its acidity and all its ſaline characters are deſtroyed. On bare expoſure to the open air, the inflammable principle is diſſipated, and the acid is combined with the aluminous earth into a perfect alum, the ſtone at the ſame time falling into powder.

The mineral, thus impregnated with alum, is elixated or boiled with water; the liquor boiled down, commonly with an addition of urine, or alkaline ley, or both together; the clear part poured off and ſet to ſhoot; the cryſtals, if not ſufficiently pure, diſſolved again, boiled down with a little more alkali, and cryſtallized afreſh. The uſe of the urine or alkali ſalt is partly to clarify the liquor, and precipitate ſuch metallic parts as it may contain, and partly to give a body to the alum, and promote the cryſtallization; the liquor of itſelf would not ſhoot, but either continue fluid, or if further evaporated, would yield only an unctuous maſs. Alkaline ſalts are found to anſwer better than urine, and hence are now in moſt places alone made uſe of, though ſome ſtill retain urine from prejudice and cuſtom. The alkali precipitates not only metallic matters, but a groſs earth which would injure the tranſparency of the ſalt, and often alſo a part of the aluminous earth itſelf, which falls to the bottom in form of a fine white meal, called at the works alum meal; this is to be rediſſolved and cryſtallized afreſh. The mineral remaining after elixation, expoſed for ſome years to the air, becomes impregnated with alum again; in ſome places this proceſs is repeated a third and fourth time.

Some earths, as the alum earth of Solfatara, and the aluminous ſlates, have a manifeſt aluminous taſte when newly dug; and hence are directly elixated, without expoſure to the atmoſphere. In ſome kinds of ſlates we may plainly diſtinguiſh the aluminous matter lying in a powdery form, betwixt the flakes or ſcales of which the ſtone is compoſed. In general, where the mineral holds but little ſulphur, it is ſufficient to lay it for a time in the open air, defended from rain by a ſhed or ſlight covering; if it participates conſiderably of ſulphur, it muſt be previouſly calcined; if very rich in ſulphur, a part of the ſulphur is firſt extracted by ſublimation, and the reſiduum worked for alum.

The alum ſlates near York, in England, are conſiderably ſulphureous; by lying long in the air, they become aluminous of themſelves; but to promote this effect they are uſually calcined. The boilers are large leaden pans, nine feet long, five feet broad, and two and a half in depth; the liquor is clarified and diſpoſed to cryſtallize by the addition of ſoda, there called kelp, and of urine. The alum ore of Schwentzel, near Duben in Saxony, above five miles from Hall, is likewiſe bituminous; this is firſt calcined, then expoſed to the air, elixated with water, and the liquor boiled down with potaſh. At Altſattel near Carlſbade, the workmen formerly uſed only urine, of which they received conſtant ſupplies from the neighbouring towns and villages. The moſt curious alum ore known is in Sweden; ſulphur, vitriol, and alum, being here obtained from one mineral, which appears to be a kind of pyrites. The ſulphur is firſt extracted by diſtillation; the reſiduum being ſtrongly calcined, boiled in water, the liquor duly evaporated and ſet to ſhoot, the vitriol cryſtallizes; the uncryſtallized liquor, treated with urine and a ley drawn from aſhes, yields alum.

The cryſtallization of alum is uſually performed in large ſtrong wooden caſks, whoſe ſtaves and hoops are all marked with numbers, that they may be readily put together; in ſome places iron veſſels are uſed. The caſks being filled with the alum liquor, evaporated to a due conſiſtence, and ſet in a cold place, the alum gradually ſhoots into large cryſtals about the ſides; the liquor in the middle is then let off by a cock in the bottom, the head of the caſk knocked out, and the veſſel turned upſide down, for the more effectual draining off of the remaining liquid. The cryſtals are then dried in a warm ſtove, and packed up in caſks; and the mother-ley, or uncryſtallized liquor, mixed with freſh aluminous leys. The metallic or vitriolic alum-ores occaſion the greateſt trouble; and the alum obtained from them, though it appears white, is never totally free from ſome metallic impregnation. Conſiderable differences are found in alum, partly from this cauſe, and partly from its being prepared with urine or pot-aſh, or with freſh or ſtale urine. Theſe differences are chiefly obſerved by the dyers, and thoſe who prepare lakes for the painters.

Alum requires about ten times its weight of water to diſſolve in. The ſolution, if the alum was pure, makes no change in the colour of ſyrup of violets; but the common ſorts change the ſyrup green, by virtue of the alkaline ſalt employed in their preparation. Fixed alkalies, volatile alkalies, and borax, added to ſolutions of alum, precipitate the earth. Its taſte is nauſeouſly ſweetiſh and aſtringent. In cryſtallization, it ſhoots into large angular maſſes, conſiſting generally of eleven planes, five of which are hexangular and ſix quadrangular.

An ounce of alum contains about five ſcruples and a half of earth, one dram and eighteen grains of vitriolic acid, and nearly five drams of water. Great quantities of alum are uſed by the dyers, calico printers, &c. the former ſteeping and boiling their ſtuffs in a compoſition made with alum, tartar, and bran; and the latter print their linens intended for reds with a compoſition of alum and ſacrum ſaturni. See DYING, and CALICO *Printing*.

Burnt ALUM is nothing more than alum expoſed to the action of the fire; by which means it liquefies, and boils up like green vitriol; and when its phlegm is evaporated, forms a white ſpongy brittle maſs: by this treatment it loſes very little of its acid; and hence almoſt totally diſſolves again in water, and ſhoots into hard compact cryſtals as at firſt. The calcined or burnt alum, as it is called, proves ſharper in taſte than crude alum, on account of the loſs of its phlegm; and imbibes humidity from the air. Four ounces will, in the ſpace of a month, gain an increaſe of one ounce. Dr. Rhuon expoſed equal quantities of burnt alum, for equal lengths of time, in a damp cellar, and in a dry upper room; the firſt gained half an ounce; the latter only five ſcruples.

If we attempt to extract the phlegm and acid of alum by diſtillation, we muſt either inject the alum by a little at a time into a tubulated retort, or put it into a common retort, of which it may fill no more than one half, and apply the fire in ſuch a manner, that the matter may be heated firſt on the ſurface, and thence gradually to the bottom. Though the fire is kept up ſtrong for a conſiderable time, we can ſcarce gain more than half the weight of the alum of a phlegmatic ſpirit. The reſiduum, expoſed to the air, imbibes moiſture, and then yields more of an acid ſpirit, the phlegm ſerving for a vehicle to the acid. Alum, diſſolved repeatedly in vinegar, parts with its water more eaſily than at firſt: it now calcines into a white mealy powder, in a warm room, or by the heat of the ſun.

ALUM *Water*, a compoſition uſed by thoſe who colour prints, &c. and made in the following manner:

Take three ounces of alum, and boil it in a quart of rain or river water, till the ſalt is diſſolved. Then take it from the fire, and after ſtanding twenty-fours to ſettle, pour off the clear liquor for uſe.

With this water they waſh their prints in order to prevent the colours from ſinking into the paper, and give them a brightneſs which they would otherwiſe want.

ALUMINOUS, an epithet applied to ſuch things as partake of the nature or properties of alum.

ALUMINOUS *Waters*, thoſe impregnated, either by nature or art, with the virtues of alum. The ſpa at Scarborough is ſaid to be of the former kind.

ALVUS, in anatomy, the lower belly or venter. See ABDOMEN.

ALYSOIDES, in botany, a diſtinct genus of plants, with cruciform flowers, and elliptical fruit, divided by an intermediate membrane into two cells, which contain a conſiderable number of ſmall roundiſh ſeeds.

ALYSSON, or ALYSSUM, in botany, is the name of a genus of plants called in Engliſh mad-wort: the flower is of the cruciform kind, and conſiſts of four leaves: the fruit is a roundiſh capſule, divided into two cells, in which are contained a number of ſmall roundiſh ſeeds.

This plant is ſaid to be aperitive and diaphoretic; but is ſeldom uſed at preſent.

ALYTARCHA, a prieſt of Antioch, who preſided in the games inſtituted in honour of the gods, over the alutai, or officers who kept order and decency at theſe feſtivals.

The word is Greek, and compounded of αλυται, and αρχος, chief.

AMA, among eccleſiaſtical writers, implies a veſſel in which wine or water were kept for the ſervice of the euchariſt.

AMABYR, a barbarous cuſtom which formerly prevailed in ſeveral parts of England and Wales, being a ſum of money paid to the lord, when a maid was married within his lordſhip.

The word is old Britiſh, and ſignifies "the price of "virginity."

AMAIN, in the ſea language, ſignifies at once. Thus to lower amain, is to lower at once, or let go the fall of the tackle.

AMALGAMA, in chemiſtry, a maſs of mercury united and incorporated with ſome metal.

The word is formed from the Greek, *αμα*, together, and *γαμεω*, to join.

AMALGAMATION, in chemiſtry, the operation of making an amalgama, or mixing quickſilver with ſome metal.

Trituration is often ſufficient to make an amalgama; but a proper degree of heat is alſo of very conſiderable uſe.

Mercury, amalgamated with a metal, gives it a conſiſtence more or leſs ſoft, and even fluid, according to the greater or ſmaller proportion of mercury employed. All amalgamas are ſoftened by heat, and hardened by cold.

Mercury is very volatile; vaſtly more ſo than the unfixed metals: moreover, the union it contracts with any metal is not ſufficiently intimate to entitle the new compound reſulting from the union to all the properties of the two ſubſtances united; at leaſt with regard to their degree of fixity and volatility: from all which it follows, that the beſt and ſureſt method of ſeparating it from metals diſſolved by it, is to expoſe the amalgama to a degree of heat ſufficient to make all the quickſilver ariſe and evaporate; after which the metal remains in the form of a powder, and being fuſed recovers its malleability. If it be thought proper to ſave the quickſilver, the operation muſt be performed in cloſe veſſels, which will confine and collect the mercurial vapours.

Of all metals gold unites with mercury with the greateſt facility; next to that ſilver; then lead, tin, and every metal, except iron and copper, the laſt of which incorporates with quickſilver with great difficulty, and the former ſcarce at all.

The amalgama of gold is thus made: take a dram of the regulus of gold, beat it into very thin plates, and upon theſe, heated in a crucible red-hot, pour an ounce of quickſilver, ſtir the matter with an iron rod, and when it begins to fume, caſt it into an earthen pan filled with water, and it will coagulate and become tractable. Gold will retain about thrice its weight of mercury.

To make an amalgama of lead: melt clean lead in an iron ladle, add to it an equal weight of melted mercury, ſtir them together with an iron rod; then let them cool, and you will have an uniform maſs of a ſilver colour, ſomewhat hard, but growing ſofter and ſofter by trituration. Put this maſs into a glaſs mortar, grind it, and mix with it any quantity of mercury at pleaſure, and it will unite with it, as ſalt with water.

The amalgama of tin is made exactly in the ſame manner, and this alſo may be diluted by the addition of mercury.

To have an amalgama of copper: take a ſolution of pure copper made in aquafortis, ſo ſtrong that the aquafortis could diſſolve no more of the metal; dilute the ſolution with twelve times its quantity of fair water; heat the liquor, and put it into poliſhed plates of iron, and the copper will be precipitated in a powder to the bottom, while the iron will be diſſolved: proceed thus till all the copper is fallen; pour off the liquor, waſh the powder with hot water, till it becomes perfectly inſipid; then dry the powder, and grind it in a glaſs mortar with an equal weight of hot quickſilver, and they will unite into an amalgama, which will alſo receive a further addition of mercury. An amalgama of copper in any other way is very difficult to make.

Pure ſilver, precipitated from aquafortis, may in the ſame manner be made into an amalgama.

From theſe operations we may perceive that the making of amalgamas is the foundation of the art of gilding, both of gold and ſilver; and that metals, by that art, may be mixed, confounded, and ſecretly concealed among one another.

AMALTHEA, in mythology, the goat that ſuckled Jupiter, and was afterwards placed by that god among the ſtars.

AMANUS, in mythology, a god of the ancient Perſians. It is ſuppoſed to have been the ſun, who m worſhipped under the image of the perpetual fire.

AMARANTA, or AMARANTE, an order of knighthood, inſtituted in the year 1653, by Chriſtina, queen of Sweden, in memory of a maſquerade, in which ſhe had aſſumed that name, which ſignifies unfading, or immortal.

AMARANTHUS, in botany, the name of a genus of plants, ſometimes called prince's-feather, the flower of which is roſaceous, and the fruit an oval capſule, containing only one large ſeed of a roundiſh compreſſed ſhape. See plate IV. *fig.* 10.

All the ſorts of amaranthus muſt be ſown on a good hot-bed, in February, or the beginning of March at fartheſt; and in about a fortnight's time (if the bed is in good temper) the plants will riſe; when you muſt prepare another hot-bed, covered with good rich light earth, about four inches thick; then raiſe up the young plants with your finger, ſo as not to break off the tender roots, and prick them into your new hot-bed, about four inches diſtance every way; give them a gentle watering to ſettle the earth to their roots; but, in doing this, be very cautious not to bear the young plants down to the ground by haſty watering, which rarely riſe again, or at leaſt ſo as to recover their former ſtrength in a long time, but very often rot in the ſtems, and die quite away.

The amaranthus tricolor and bicolor muſt be kept longer under the frames than the cock's combs; and, in order to have them very beautiful, it will be proper to make a freſh hot-bed in a glaſs-caſe; or, where ſuch a conveniency is wanting, to erect ſome of the lights which were placed over cucumbers, round an hot-bed, and cover thoſe with the ſame lights on the top, ſo as to reſemble a glaſs-ſtove. On this hot-bed, you ſhould place your amaranthus at ſuch a diſtance from each other, as to allow them room to ſpread; obſerving to refreſh them often with water, and in warm weather let them have plenty of freſh air. With this management the plants may be raiſed five or ſix feet high, and their leaves will come to the moſt beautiful colours; after which they may be expoſed to the open air, and removed to adorn the ſeveral parts of the garden. *Miller's Dict.*

AMARANTHOIDES, in botany, a diſtinct genus of plants, with floſculous flowers collected into a ſquamoſe head, and a roundiſh fruit.

AMATORII *Muſculi*, in anatomy, thoſe muſcles of the eye that draw it ſideways, and aſſiſt the look called ogling.

AMAZON, in antiquity, a bold daring woman, whoſe breaſts have been cut off to render her more proper for fighting. In a more limited ſenſe, it implied one of the ancient nation of women, who inhabited that part of the Leſſer Aſia, now called Amaſia. We alſo read of Scythian, German, Lybian, and American amazons.

AMAZONS, in a figurative ſenſe, is an appellation given to bees from their being governed by a queen.

AMBASSADOR, a perſon ſent in a public character from one ſovereign to another.

The word is derived from the low Latin, *ambaſciator*, formed from *ambactus*, which among the ancient Gauls ſignified ſervant, client, domeſtic, or officer.

Ambaſſadors are either ordinary or extraordinary.

AMBASSADOR *Ordinary* is a perſon reſiding at another court for keeping up a good intelligence between the two powers, taking care of the intereſt of his maſter, and negociating ſuch affairs as may occaſionally happen. Ambaſſadors of this kind have not been known above two centuries; before that time all ambaſſadors were extraordinary, and retired as ſoon as they had finiſhed the affair they were ſent to negociate.

AMBASSADOR *Extraordinary* is a perſon ſent to the court of a foreign power, on ſome particular and preſſing affair, as to conclude a peace, or a marriage, make a compliment, &c.

In fact, there is no eſſential difference between ambaſſadors ordinary and extraordinary; the motive of their ambaſſies alone diſtinguiſhes them: they are equally entitled to the privileges given to ambaſſadors by the law of nations.

The name of ambaſſador, ſays Cicero, is ſacred and inviolable. And this has always been the opinion of all nations; for we find that David thought the affront offered to his ambaſſadors, a ſufficient reaſon for making war againſt the Ammonites; and Alexander put the inhabitants of Tyre to the ſword for inſulting his ambaſſadors.

AMBERVALIA, in antiquity, a ceremony among the Romans; when, in order to procure from the gods an happy harveſt, they conducted the victims thrice round the corn fields, in proceſſion, before they were ſacrificed.

AMBE, among ſurgeons, is the name of an ancient inſtrument for reducing a diſlocated ſhoulder.

This inſtrument has received various improvements at different times, and by different authors. Mr. Freke, late ſurgeon to St. Bartholomew's hoſpital, both improved the machine, and rendered it portable; we ſhall therefore give a deſcription of the ambe, according to his conſtruction.

This machine, (repreſented on plate IX. *fig.* 9.) which conſiſts of two boxes, A, A, joined at the ends by two hinges, contains, when folded together, every thing that can poſſibly be wanted in reducing a diſlocated ſhoulder; and it may ſo eaſily be made uſe of, without the aſſiſtance of any other than the ſurgeon employed, that (ſays the ingenious author) I may venture to affirm, a patient may be ſet down, the inſtrument applied, and the ſhoulder reduced, in one minute, ordinarily ſpeaking.

The length of this inſtrument, when ſhut up, is one foot eight inches, its breadth nine inches, and its thickneſs three inches and a quarter. When it is opened, it is kept ſo by two hooks fixed on the backſide of it; and when one end of it ſtands on the ground, the other ſtands high enough to become a fulcrum, or ſupport of the lever B, B, which is fixed on a roller *b*, by a large wood-ſcrew, which turning ſideways, as well as with the roller, it obtains a circumrotatory motion; ſo that it will ſerve to reduce a luxation, either backward, forward, or downward.

The roller, on which the lever is fixed, is juſt the diameter of the depth of one of the boxes, into which are driven two iron pins, the ends of which are received by the two ſides of the box, which are an inch thick.

The lever is two feet four inches long, and is cut off and joined again by two hinges C, to fold up ſo as to be contained in the boxes. On the backſide of it is a hook to keep it ſtraight; the other end of it is to hang over the roller about an inch and an half, which is to be excavated and covered with buff-leather, for the more eaſy reception of the head of the os humeri.

Two iron cheeks D, are ſcrewed on each ſide of the lever, to receive through them an iron roller, which has two holes through it to receive two cords coming from a brace F, fixed on the lower head of the os humeri; for on no other part of the arm above the cubit can a bandage for this purpoſe be uſeful; for, if it be applied on the muſcular part of the arm, it never fails ſlipping down to the joint before you can extend the limb.

The iron roller has a ſquare end, on which is fixed a wheel G, within the cheek notched round, which works as a ratchet, on a ſpring catch underneath the lever, by which it is ſtopped, as you wind it with a winch; and may at pleaſure be let looſe, as there ſhall be occaſion for it, by diſcharging the catch. We come now to deſcribe the brace F, which, compared with common bandages, is of more conſequence than can eaſily be imagined by unexperienced perſons. It conſiſts of a large piece of buff-leather, big enough to embrace the arm, ſewed on two pieces of ſtrong, iron, curved plates, riveted together, one of them having an eye at each end to faſten two cords in; the other is bent at the ends into two hooks, which are to receive the cords, after they have croſſed over the arm above.

In order to keep the patient ſteady in his chair from coming forward, or letting the ſcapula riſe up on depreſſing the lever, after the limb is extended by the winch, there muſt be fixed over the ſhoulder a girth with two hooks at the ends of it, long enough to reach to the ground on the other ſide, where it muſt be hooked into a ring I, ſcrewed into the floor for that purpoſe. *Philoſophical Tranſactions.*

AMBE, among anatomiſts, implies the ſuperficial jutting out a bone.

AMBER, *ſuccinum*, or *electrum*, in natural hiſtory, a pellucid and very hard inflammable ſubſtance, of an uniform ſtructure, a bituminous taſte, a very fragrant ſmell when rubbed, and highly endowed with that remarkable property called electricity.

Amber is a ſolid mineral bitumen; not as ſome have ſuppoſed a vegetable reſin, or inſpiſſated juice, introduced into cavities in the earth, and there indurated and ſomewhat changed in its quality; nor is it a true marine production, though ſometimes found in the ſea.

This bitumen is met with plentifully in regular mines in ſome parts of Pruſſia; the upper ſurface is compoſed of ſand, under which is a ſtratum of loam, and under this a bed of wood, partly entire, but chiefly mouldered or changed into a bituminous ſubſtance; under the wood is a ſtratum of vitriolic or rather aluminous mineral, and under this another bed of ſand, in which the amber is found. Strong ſulphureous exhalations are often perceived in the pits. Helving relates, that wherever there is amber, there is always bituminous earth and foſſil wood, a gravelly matter, vitriol, nitre, and ſulphur; and that the matter of the amber reſides in the foſſil wood. The obſervation appears to be juſt, except in regard to nitre, which is never found in the amber pits; ſome aluminous matter was doubtleſs miſtaken for nitre. Conſiderable quantities are met with alſo in the ſea, near the amber ſhores, particularly after a ſtorm, the ſea having probably waſhed out the mineral from the earth.

The principal amber pits are in the territory called Sandlande, between Pillau and Fiſchhauſen, near the villages Groſshubenick, Groſsdirſchken, Warnicken, Strobſchner, Rittener, Palmnick, &c. The ſhores on which amber is chiefly fiſhed for, are thoſe called Krecke, Nodens, Laſſnick, Kinck, Krapellen, Krackſtepellen, Crimichen, and Thieſkim or Bruſterort. The manner of fiſhing for it is pretty well deſcribed in *Hartman's Hiſtoria Succini Pruſſici*. The digging of amber is a very dangerous work; the ground not being ſtony or rocky, as in metallic mines, but ſandy or loamy, and hence very ſubject to fall in when hollow underneath. His Pruſſian majeſty receives a large annual revenue from this commodity: he has a peculiar council called the Amber-chamber; and no one but thoſe appointed for that purpoſe is permitted to dig or fiſh for amber in his dominions. Small quantities of amber are met with alſo in Bohemia, Sileſia, Saxony, Hungary, France, &c. The pieces of amber now and then found in theſe places were not perhaps originally produced there, but carried thither by the flood.

Various kinds of ſubſtances are often encloſed in maſſes of amber, as drops of water, which paſs from ſide to ſide upon moving the maſs, ſmall bits of wood, moſs, leaves of plants, &c. a variety of inſects, particularly gnats, flies, ſpiders, ants, moths, butterflies, graſshoppers, bees, worms, cantharides, caterpillars, crickets, maggots, lice and fleas. There are reports alſo of frogs, vipers, fiſhes, and other large animals being found in maſſes of amber, and ſuch are figured in *Mercatus's Metallotheca*; but moſt of theſe are artificial preparations; even the fiſh in amber, in his Pruſſian majeſty's Repoſitory, is manifeſtly factitious. The generality are however natural. Hence it is evident, that this bitumen has once been in a fluid ſtate, tho' we cannot conclude that it ever was a liquid or oily matter, and acquired its conſiſtency and ſolidity by degrees. Appearances are rather contrary to this ſuppoſition. The inſects found in amber have nothing of thoſe ſtrained or diſtorted poſtures which animals are naturally thrown into upon endeavouring to diſengage themſelves when entangled in a viſcous liquid. We often ſee pieces of amber in which there are perfect flies, with the wings and feet beautifully expanded as if they were ſtill flying. It is therefore moſt probable that the amber was generated inſtantaneouſly from the concourſe of mineral oil or petroleum, with vitriolic acid, in the form of vapours, which at once concreted together, and embalmed the inſects that happened to lye in their way, with a more durable and precious covering than has ever fallen to the lot of the moſt magnificent monarchs.

A bituminous wood is conſtantly to be met with in the Pruſſian amber pits: this however does not appear at all neceſſary to the formation of amber; for that bitumen is alſo found in Italy, where foſſil wood is unknown, but plenty of mineral oil or petroleum.

There are different ſorts of amber in regard to external appearance; opake and tranſparent; white or whitiſh, yellowiſh or yellow, greeniſh, browniſh, bluiſh, reddiſh, or browniſh red; what is called black amber is no true amber, but bitumen of the pit-coal, aſphaltum, or jet kind. Some divide amber into native and factitious. There are indeed artificial maſſes reſembling amber in appearance; but no true amber has hitherto been produced by art. In Holland, a vegetable reſin, whoſe proper name is gummi de loock, is ſold under the name of American amber: this, when in conſiderable maſſes, and by itſelf, is eaſily diſtinguiſhed from the genuine amber, by its having leſs electricity, wanting the peculiar ſtrong ſmell which amber emits in burning, by its greater ſolubrity in ſpirit of wine, and not yielding the ſame principles as amber in diſtillation: ſmall pieces of the reſin, mixed among true amber, are diſcovered with more difficulty; and this abuſe is not unfrequently practiſed.

Amber is divided by the workmen into different aſſortments, according to the ſize of the maſſes; the ſmalleſt and coarſeſt bits are called ſandſteiri; the ſomewhat larger, ſchulg; thoſe which are ſtill larger, firniſs, or varniſh amber; the pieces which are large enough to be turned into beads, or other ornaments or utenſils, are named from the works for which they are judged to be fit. There are other diviſions taken from the quality of the maſſes. Of the opake ambers, the moſt valuable is the flaky or ſcaly; next to this the undulated or waved; and next in order the cloudy, the cauliflower or pearl-like, the milky, the citron yellow, the wax coloured, the dark yellow, the browniſh, and the dark brown, which laſt is the coarſeſt of all. The tranſparent ambers are divided into reddiſh, gold yellow, like a yellow glaſs, citron yellow, pale yellow, and whitiſh. Of all theſe there are ſeveral ſubdiviſions, commixtures, or intermediate ſhades; and ſometimes we meet with pieces of other colours, as greeniſh, bluiſh, coffee-coloured, opal-coloured, &c. With regard to the tranſparent ambers, it may be proper to take notice, 1. That inſects or other foreign bodies are obſerved chiefly in theſe; poſſibly they may often be lodged alſo in opake amber, though the opacity of the maſs prevents our ſeeing them. 2. That opake amber is capable of being made tranſparent by art; and hence that all our tranſparent ambers were not naturally ſuch. 3. That the fine gold yellow tranſparent ſort is entirely natural; the common methods of improving the tranſparency, weakening the colour. There are means of communicating to amber a variety of colours: one Somnelſon, an excellent artiſt at Breſlau, not only made opake amber tranſparent, but tinged it red, blue, violet, of a purpliſh, green, and white; and cut it into brilliants, necklaces, ear-pendants, bracelets, &c. in imitation of precious ſtones; as alſo into ſpectacles, microſcopes, priſms, burning lens's, &c. of which an account may be ſeen in the Breſlau collections. 4. That amber clarified by art is always harder, and leſs electric than in its natural untranſparent ſtate.

Schroder relates, that yellow amber is made white by boiling in ſalt-water; and later writers have copied this account: on trial, however, ſalt water is not found to have any ſuch effect. The workmen have two methods of clarifying amber; one by ſurrounding the amber with ſand in an iron pot, and cementing it with a gradual fire for forty hours; ſome ſmall pieces placed near the ſides of the veſſel being occaſionally taken out for judging of the effect of the operation. The ſecond method, which is that moſt commonly practiſed, is by digeſting and boiling the amber about twenty hours in rape-ſeed oil, by which it is rendered both clear and hard; treated in the ſame manner with linſeed oil, it does not become clear.

Sendelius informs us, that he clarified pieces of cloudy amber, by applying them to the flame of a candle, and rubbing them now and then with tallow; and that opake pieces, boiled with fleſh and with fiſh, ſhewed a diſpoſition to become clear. The moſt deſirable point in the manufactures of amber would be, to find a method of melting ſmall pieces into a large one; but all attempts of this kind have hitherto miſcarried.

It is no ſmall piece of art to procure a total ſolution of amber; various methods have been tried with alkalies, acids, oil, inflammable ſpirits, dulcified ſpirits, balſams, and other menſtrua, without the wiſhed for ſucceſs. Hoffman relates, that he has diſſolved amber by two methods; one by putting two parts of oil of almonds, and one of powdered amber, into a glaſs veſſel, and ſetting the veſſel in Papin's digeſter, filled about one third with water; the cover of the digeſter being ſtrongly ſecured, and a moderate fire kept up for above an hour, the amber was reſolved into a tranſparent gelatinous maſs, on the ſurface of which floated a little fluid oil. The other method conſiſted in boiling powdered amber in water, with an equal weight of cauſtic nitre; this corroſive alkali occaſioning, he ſays, almoſt all the amber to be diſſolved. Theſe experiments muſt be left to future trials: we ſhall however obſerve, that neither of them proved entirely ſatisfactory. Henckel has carried the affair much farther, pretending to prepare amber, without burning, and without alkalies, ſo as to diſſolve totally in ſpirit of wine: of this aſſertion we can form no judgment till the fact is produced. Of the common menſtrua, there is not one which totally diſſolves this concrete: in Papin's digeſter, the amber perhaps is only ſoftened. Moſt liquors however extract ſome portion of it. A tincture made in vinous ſpirits is kept in the ſhops. Some have thought it to promote the action of the ſpirit by fixed or volatile alkaline ſalts: but theſe kinds of additions give very little, if any, aſſiſtance to the ſpirit as a menſtruum, and are accompanied with an inconvenience of rendering the tincture unfit for the chirurgical uſes to which it is commonly applied. Highly rectified ſpirit of wine extracts of itſelf a ſufficiently ſtrong tincture from amber: the admixture of alkaline ſalts deepens the colour of the liquor, without increaſing the quantity taken up. If the ſimple tincture is required to be more ſaturated with the amber, it may be eaſily rendered ſo by drawing off a part of the ſpirit, which may be reſerved for the like uſes again, as being impregnated with the more ſubtile parts of the amber. If the ſpirit be totally abſtracted, a balſamic matter or reſin is left in the form of an extract. This is employed by ſome as an ingredient in compoſitions for pills. Water mixed with the tincture renders it turbid; but ſcarce any precipitation enſues: though in ſeveral books of pharmacy a magiſtery of amber is directed to be prepared by this means.

Oil and Salt of AMBER. Amber melts and burns in the fire, and emits a ſtrong peculiar ſmell. Diſtilled in a ſtrong heat it yields a phlegm, an oil, and a particular ſpecies of volatile ſaline matter. The diſtillation is performed in earthen or glaſs retorts, frequently with the addition of ſand, powdered flints, bricks, lime, elixated aſhes, bole, loam, pumice, ſea-ſalt, coals, &c. Conſiderable differences are obſerved in the products, according to the additions made uſe of; with ſome the ſalt proves yellowiſh and dry, with others browniſh or blackiſh, and unctuous or ſoft like an extract; with ſome the oil is throughout of a dark brown colour, with others it proves externally green or greeniſh, with elixated aſhes in particular of a fine green. The quantity of oil and phlegm is greateſt when coals, that of ſalt when ſea-ſalt is uſed. The common addition is ſand, of which two parts are mixed with two or one of amber in coarſe powder. Thoſe whoſe ſole buſineſs is to diſtil amber in Pruſſia, and whom long experience has taught the moſt advantageous methods of doing it, uſe no addition. The Engliſh chemiſts likewiſe diſtil their amber without addition, and ſell their reſiduum to the japanners, who prepare from it the fineſt black varniſh. See the article VARNISH.

In order more perfectly to collect the ſalt, which is the moſt valuable product in this operation, the Pruſſian workmen frequently change the receiver during the diſtillation, and keep apart the phlegm and the light oil which ariſe at firſt. They purify the ſalt by placing it for a time upon bibulous paper, which abſorbs a part of the oil, and changing the paper ſo long as it receives any oily ſtain. Where a farther depuration is required, the ſalt is ſcraped out as clean as poſſible from the neck of the retort, or wherever elſe it has concreted, and waſhed off with water. The whole diſtilled matter is then to be mixed with a conſiderable quantity of hot water, the mixture well ſtirred together with a wooden ſpatula, the water, after ſettling, poured off, and freſh parcels of hot water added, to extract all the ſaline matter that may be retained by the oil: the ſalt ſeparated at firſt is to be diſſolved in this liquor, the ſolution filtrated, evaporated in glaſs veſſels to a proper pitch, and then ſet in the cold; the ſalt will ſhoot into fine ſpongy cryſtals, which may be gently dried upon bibulous paper: the remaining liquor may be further inſpiſſated and cryſtallized afreſh, or evaporated to dryneſs. The ſalt obtained by theſe laſt proceſſes will turn out browner and browner, and is therefore to be reſerved for inferior purpoſes, or further purified by repeating the ſolution, filtration, and cryſtallization. This ſalt may alſo be purified by ſublimation. It effervesces with alkalies and abſorbent earths, and forms with them compound ſalts ſomewhat reſembling thoſe made with vegetable acids; its acid matter ſeeming to have a conſiderable analogy to the acids of the vegetable kingdom, and being eſſentially diſtinct from the three called mineral acids: mixed with acids, it makes no ſenſible commotion. By theſe characters this ſalt may be diſtinguiſhed from all the other matters that have been mixed with or vended for it. With regard to its virtues, it is accounted aperient, diuretic, and antihyſteric: its great price has prevented its coming much into uſe, and probably its real virtues, though doubtleſs conſiderable, fall greatly ſhort of the opinion that has been generally entertained of them.

The oil of amber is rectified by diſtilling it over, either by itſelf, or with different additions, as burnt bones, lime, elixated aſhes, chalk, tobacco-pipe clay, potaſh, &c. The beſt method is to diſtil it with common water, and repeat the diſtillation ſeveral times with freſh parcels of water: by this method we obtain a clear limpid oil, a large quantity of thick pitchy matter remaining behind. This oil has a ſtrong bituminous ſmell, and a hot pungent taſte; and approaches more to the nature of the mineral petrolea than of the vegetable or animal diſtilled oils. It is ſometimes given internally, in doſes of ten or twelve drops, as an antihyſteric and emmenagogue; and ſometimes employed externally in antihyſteric, paralytic, and rheumatic liniments, or unguents.

AMBERGRIS, *Ambragriſea*, in natural hiſtory, a marine bitumen, about the conſiſtence of wax, of a laminated ſtructure, as if the maſs was formed by a ſucceſſive appoſition of matter.

It is ſometimes found in the waters of the ſea, ſometimes thrown out upon the ſhores, and ſometimes met with in the ſtomachs of whales and other fiſhes frequently intermixed with little bones, claws of birds, and other like matters.

Theſe circumſtances have given riſe to many ridiculous opinions concerning its origin, as its being the excrements of birds or fiſhes, generated in the ſtomachs of fiſhes like bezoar, being a ſort of wax produced by bees upon rocks, &c.

The greateſt quantities of ambergris are met with in the Eaſt Indies, about the iſland Madagaſcar, the Molucca iſlands, Mauritius and Neykotarres, the weſtern Sumatra iſlands, about the iſland Borneo and Cape Comorin, near Malabar, and on the Ethiopian coaſt, which, from Solafa to Brana, is ſaid to be very rich in ambergris. Pieces are ſometimes met with of an extraordinary ſize. Chevalier and Garcias mention a piece weighing no leſs than three thouſand pounds, found in 1555 at Cape Comorin, and ſold for aſphaltum: and Joh. Hugo von Lindſchott informs us, that a maſs of thirty quintals was found at the ſame Cape. Monaides and Franciſcus Hernandez mention a piece of an hundred pounds; Garcias, one as large as a man, and another which was ninety palms in length and eighteen in breadth; Montanus, one of an hundred and thirty pounds; Kempfer, one exceeding that weight, found in his time in the province of Kinokuni, in Japan. The Dutch Eaſt-India company purchaſed of king Tidori in 1693, for eleven thouſand rixdollars, a piece of ambergris, weighing one hundred and eighty-two pounds, which was kept many years at Amſterdam, and ſeen by thouſands; but afterwards broken and ſold in pieces. It was of the ſhape of a tortoiſe, and meaſured five foot eight inches by two foot two. Nicholas Chevalier has given a particular deſcription of it in a Treatiſe printed at Amſterdam in 1700.

Ambergris is of various colours, aſh-coloured, whitiſh, yellowiſh, blackiſh-grey, brown, black, ſtreaked, and ſpotted. The pieces which have been ſwallowed by fiſhes are the leaſt eſteemed, as receiving an ill ſmell from the animal. The quite blackiſh and the quite whitiſh are to be rejected; and thoſe which are ſmooth and of a uniform texture, we may ſuſpect of being counterfeits. The aſh-grey-coloured ambergris, with whitiſh, blackiſh, and yellowiſh ſtreaks or ſpecks, is accounted the beſt, eſpecially when intermixed with beaks of birds, bits of cuttle-bone, or other like matters; not that theſe are eſſential to ambergris, but they are marks of its being genuine. The beſt ambergris is light, like wax to the touch, crumbly, yet ſomewhat tenacious, ſo as to ſtick to the mortar or peſtle; it has an agreeable ſmell, but no remarkable taſte: it eaſily melts in the fire, takes flame from a candle, and burns away without intermiſſion.

Ambergris is counterfeited or adulterated with wax, reſin, ſtorax, benzoine, amber, labdanum, muſk, civet, aloes wood, old decayed aſh-wood, rice-meal, tree-moſs, and other like ſubſtances. Theſe abuſes are eaſily detected. The counterfeit ſorts are commonly uniform throughout, both in colour and texture, like a paſte or maſs of pills, which the genuine ambergris never is. The former commonly ſoften ſooner in the warm hand, and never have the true ambergris ſmell, no art being able to perfectly imitate this. The ſmell is moſt readily diſtinguiſhed in melting the ambergris on burning coals, or in a ſilver ſpoon over a candle, or in the flame; it ſmells at laſt like burning amber, but not ſo ſtrong. The true ambergris bubbles up in melting, and after fuſion appears brown. Some judge of its genuineneſs from the appearance of a matter, like melted reſin upon piercing the maſs with a red-hot needle, or other ſlender inſtrument. Menſtrua likewiſe afford ready methods of diſtinguiſhing the genuine from the ſophiſticated.

Ambergris melts in boiling water like a reſin, and communicates to the liquor a little of its ſmell, which ariſes along with the water in diſtillation. It diſſolves in linſeed oil, if the ambergris be previouſly melted, and the oil freed from water. It has been hitherto looked upon as exceedingly difficult, and not at all totally ſoluble in ſpirit of wine; the ſpirit being ſuppoſed to extract only a ſmall part, as it does from amber. It has however been found that this menſtruum may be made to diſſolve ambergris both readily and totally. If ambergris, broke in pieces, be put into twelve times its weight of a good tartarized ſpirit of wine, or of a plain highly rectified ſpirit, the ſpirit will extract little till it begins to boil, but will then quickly diſſolve the whole of the ambergris, except its impurities. If the ſpirit be impregnated with any eſſential oil, whether by drawing it over from oily vegetables, or by adding the oil itſelf, it will diſſolve ambergris more readily, and in a leſs degree of heat than would otherwiſe be neceſſary. The rectified oil of amber has been alſo tried, and found to promote the action of the ſpirit; but the expreſſed oils, recommended by Schroder, have no effect. The tincture made in tartarized ſpirit is of a deep reddiſh colour; that made in pure ſpirit ſcarcely any. The reſiduum appears of a large volume, though when dried proves to be only a very ſmall quantity of a fine earthy matter, amounting, when the ambergris is free from viſible impurities, to a grain or two upon two ſcruples. It is probable that ambergris has often been diſſolved, though the paleneſs of the ſolution and apparent bulk of the reſiduum have induced the operator to think otherwiſe. In keeping the tincture or ſolution, if the veſſel be looſely ſtopt, ſo as to ſuffer a part of the menſtruum to exhale, a proportionable quantity of the ambergris precipitates, in form of a white unctuous ſubſtance, like tallow, ſoluble again upon adding more ſpirit. Lemery looked upon this as wax, and hence endeavoured to prove that ambergris proceeded from the labour of bees.

Dr. Grimm gives an analyſis of ambergris by diſtillation in the *Ephemerides naturæ curioſorum*. An ounce diſtilled in a glaſs retort, yielded firſt an aqueous liquor, then, as he calls it, a ſpiritual liquor, afterwards a yellow oil with a ſmall quantity of volatile ſalt, a pitch-like matter remaining in the retort. He obſerves, that the liquor, the oil, the ſalt, and the reſiduum, were all ſimilar to thoſe obtained from amber, except that the oil was in ſmell more agreeable.

This analyſis of ambergris confirms the opinion that this concrete, whoſe origin was formerly ſo much diſputed, is truly a bitumen of the amber kind.

Ambergris is uſed principally as a perfume, in balſams, ſnuffs, dentifrices, hair-powders, waſh-balls, &c. It was formerly held in ſome eſteem as a medicine, and ſaid to poſſeſs nervine, analeptic, aphrodiſiac, cephalic, and other virtues; but is at preſent little regarded. A tincture of it is ſometimes prepared with ſpirit of roſes. This ſpirit has no advantage as a menſtruum for the ambergris above ſimple ſpirit of wine, though it may in ſome caſes be an uſeful addition in point of ſcent; ſolutions of ambergris by itſelf having very little ſmell. And hence it is uſed as an ingredient for heightening the odours of other bodies, as aromatic waters, ſpirits, &c. The principal ſecret in this operation conſiſts in adding the perfume ſo ſparingly, that while it heightens and improves the ſmell of the ſubſtance it is joined with, it may not betray its own. A few drops therefore of the tincture of ambergris may be very advantageouſly added to any of the odoriferous waters, as hungary, lavender, &c. Common water diſtilled from ambergris proves conſiderably impregnated with its fragrance.

AMBIDEXTER, a perſon who uſes both hands alike, and with the ſame dexterity.

The word is Latin, *ambidextra*, and compounded of *ambo*, both, and *dextra*, right hand.

AMBIDEXTER, among lawyers, implies a juror who receives money from both parties for giving his verdict.

AMBIGENAL *Hyperbola*, a name given by Sir Iſaac Newton, in his *Enumeratio Linearum Tertii Ordinis*, to one of the triple hyperbolas of the ſecond order, having one of its infinite legs falling within an angle formed by the aſymptotes, and the other without that angle. As let AC, CD, (plate X. *fig.* 1.) be two aſymptotes, and EEGF one of theſe hyperbolas; then if the infinite leg GE falls within the angle ACD, and the infinite leg GF without that angle, the ſaid hyperbola is called *ambigenal*.

AMBIGUITY, in grammar and rhetoric, a defect in language, whereby words are rendered ambiguous, or capable of a double meaning.

The word is Latin, and compounded of *ambo*, both, and *ago*, to carry.

AMBIT, *Ambitus*, of a figure, in geometry, is the perimeter or ſum of all the lines that include it.

AMBLE, or AMBLING, in horſemanſhip, a peculiar kind of pace, wherein a horſe's two legs of the ſame ſide move at the ſame time.

The ambling horſe changes ſides at each remove, two legs of a ſide being in the air, and two on the ground at the ſame time. An amble is uſually the firſt natural pace of young colts, which they quit as ſoon as they have ſtrength enough to trot: there is no ſuch thing as an amble in the manege, the riding-maſters allowing of no other paces beſides walk, trot and gallop; their reaſon is, that a horſe may be put from a trot to a gallop without ſuch ſtop, which loſes time, and interrupts the juſtneſs and cadence of the manege.

There are various methods and practices of diſcipline for bringing a young horſe to amble. Some chooſe to toil him in his foot pace, through new ploughed fields, which naturally inures him to the ſtroke required in the amble; but this diſorderly toil is very apt to weaken, and ſometimes to lame a young horſe. Others attempt it by ſtopping him in a gallop and trot; ſo that loſing both he neceſſarily ſtumbles on an amble; but this is apt to ſpoil a good mouth and rein, and expoſes the horſe to the danger of an hoof-reach or ſinew-ſtrain, by over-reaching, &c. Others prefer ambling by weights as the beſt way; and to this end ſome over-load their horſe with exceſſive heavy ſhoes, which are apt to make him interfere or ſtrike ſhort with his hind feet. Others fold leaden weights about the fetlock paſterns, which are not only liable to the miſchiefs of the former, but put the horſe in danger of incurable ſtrains, cruſhing of the coronet, and breeding of ring-bones, &c. Others load the horſe with earth, lead, &c. which may occaſion a ſwaying of the back, over-ſtraining of the fillets, &c. Some endeavour to make him amble in hand, before they mount his back, by means of ſome wall, ſmooth pole, or rail, and by checking him in the mouth with a bridle-hand, and correcting him with a rod on the hinder hoofs, and under the belly, when he treads falſe; but this is apt to drive a horſe to a deſperate frenzy, before he can be made to underſtand what they would have him do, and to rear, ſprawl out his legs, and make other antic poſtures, which are not eaſily quitted again. Others think to effect it by a pair of hind ſhoes, with long ſpurns or plates before the toes, and of ſuch length, that if the horſe offers to trot, the hind foot beats the fore foot; but this occaſions wounds of the back-ſinews, which often bring on an incurable lameneſs. Some attempt it by folding fine ſoft liſts ſtrait about his gambrels in the place where he is gartered for a ſtifle ſtrain, and turn him thus to graſs for two or three weeks; and afterwards take away the liſt. This is a Spaniſh method, but diſapproved; for though a horſe cannot then trot but with pain, yet the members muſt be ſufferers; and though the amble be gained, it muſt be ſlow and unſightly, becauſe attended with a cringing in the hind parts.

The beſt way is to try with the hand by a gentle and deliberate racking, and thruſting the horſe forwards, by helping him in the weeks of his mouth with your ſnaffle, which muſt be ſmooth, big, and full; and correcting firſt on one ſide, and then on the other, with the calves of your legs, and ſometimes with a ſpur. If you can make him of himſelf to ſtrike into an amble, though ſhuffling and diſorderly, there will be much labour ſaved; for that aptneſs to amble will make him with more eaſe and leſs danger endure the tramel, and find the motion without ſtumbling or amazement; but if you perceive he will by no means either apprehend the motions or intentions, then ſtruggle no longer with him, but apply the tramel immediately. See TRAMEL. *Newcaſtle's Horſemanſhip*.

AMBLYGONAL, in geometry, an epithet applied to any thing obtuſe angular, as a triangle, one of whoſe angles is obtuſe, or more than 90°, or other plane figure that has one or more obtuſe angles.

The word is formed from the Greek, αμβλυς, obtuſe, and γωνια, an angle.

AMBLYOPY, among phyſicians, ſignifies an obſcuration of the ſight, ſo that objects at a diſtance cannot be clearly diſtinguiſhed.

The word is Greek, αμϐλυωπια, and compounded of αμβλος, dull, and ωψ, the eye.

AMBO, or AMBON, among the ancients, was a kind of pulpit, or reading deſk, where that part of divine ſervice called the gradual was performed.

AMBON, in anatomy, the cartilaginous margin of thoſe ſockets into which the prominent parts of bones are inſerted in ſome ſpecies of articulation.

AMBROSIA, among the ancient pagans, ſignified the ſolid food of the gods, in contradiſtinction to their drink, which was called nectar.

The word is Greek, and compounded of α, priv. and βροτος, mortal; becauſe they ſuppoſed that whoever eat of it was rendered immortal.

AMBROSIA, in botany, the name of a diſtinct genus of plants, with floſculous flowers, divided into five ſegments; but the fruit, which in ſome meaſure reſembles a club, grows on other parts of the plant.

AMBROSIAN *Office*, in eccleſiaſtical hiſtory, a particular office, or form of worſhip, uſed in the church of Milan; and ſo called from its author, Ambroſe, archbiſhop of Milan in the IVth century.

Originally, each church had its particular office; and even when the pope took upon him to impoſe the Roman office on all the weſtern churches, that of Milan ſheltered itſelf under the name and authority of St. Ambroſe; from which time the Ambroſian ritual has obtained in contradiſtinction to the Roman ritual.

AMBUSCADE, in military affairs, implies a body of men poſted in ſome ſecret or concealed place, till they find an opportunity of falling upon the enemy by ſurprize.

AMBUSTION, in ſurgery, the ſame with what we generally call a burn. See the article BURN.

AMEA, in botany, the name of a plant with large alated leaves, which, being dried and powdered, are uſed by the natives of Guinea for ſtopping bleedings at the noſe.

AMEL, a term frequently uſed by Mr. Boyle for enamel. See ENAMEL.

AMEN, a ſolemn concluſion to all the prayers of the church; and ſignifies, ſo be it.

The word is Hebrew, and formed from the verb, *aman*, which in the paſſive voice ſignifies to be true, faithful, &c.

There is alſo formed from this noun a kind of affirmative adverb, ſignifying truly, verily; and in this ſenſe it is often uſed in the Goſpels.

The Rabbins are of opinion that the word Amen is formed from the initial letters of *Adonia*, *Melech Neeman*, the lord, the faithful king; an expreſſion common among the Jews, when they would add a weight or ſanction to what they affirmed.

AMENDMENT, in law, ſignifies the correction of an error committed in a proceſs, which may be amended after judgment, unleſs the error lies in giving judgment; for in that caſe it is not amendable, but the party muſt bring a writ of error.

AMENDMENT, in a literary ſenſe, implies the correction of ſome impropriety in the former edition of a book.

AMENTACEOUS, in botany, an epithet applied to ſuch flowers as have an aggregate of ſummits hanging down in the form of a rope or cats-tail.

AMERCEMENT, or AMERCIAMENT, in law, a pecuniary puniſhment impoſed on offenders at the mercy of the court.

It differs from a fine in being impoſed arbitrarily in proportion to the fault; whereas a fine is a certain puniſhment ſettled expreſsly by ſome ſtatute.

AMERICA, one of the four grand diviſions of the earth. It is a vaſt continent, extending from 80 deg. north latitude, to 58 deg. ſouth; and from 35 deg. to 145 deg. weſt longitude. It is bounded on the weſt by the Atlantic ocean, which ſeparates it from Europe and Africa; and on the weſt by the Pacific ocean, or South-ſea, which divides it from Aſia.

This prodigious tract of land is divided into two peninſulas called North and South America, and connected together by the iſthmus of Darien.

It is at preſent poſſeſſed by different nations of Europe: but Spain has by far the largeſt ſhare; enjoying Old and New Mexico, Terra-Firma, Peru, Chili, Patagonia, and Paraguay; beſides a great number of iſlands, among which are Cuba, Hiſpaniola, Porto Rico, and Trinidad. The Portugueſe are maſters of the extenſive country of Brazil. The Britiſh poſſeſs the provinces of Eaſt and Weſt Florida, Georgia, South and North Carolina, Virginia, Maryland, Penſylvania, the two Jerſies, New York, New England, New Scotland, Canada, New Britain, and Hudſon's-Bay: together with the iſlands of Jamaica, Barbadoes, St. Chriſtophers, &c. Newfoundland, Cape-Breton, and many others. The French claim an extenſive country to the weſtward of the river Miſſiſſippi, and are in poſſeſſion of the iſlands of Caen, Martinico, Guadaloupe, St. Lucia, &c. The Dutch are poſſeſſed of Surinam, and ſome of the iſlands on the north coaſt of Terra Firma. The iſland of St. Thomas belongs to Denmark.

AMETHYST, *Amethyſtus*, in natural hiſtory, a gem, or precious ſtone of a purple colour, ſometimes approaching to violet, and ſometimes fading to a pale roſe-colour.

Sometimes it is found colourleſs, and may at any time be made ſo by expoſing it to the fire; in which pellucid, or colourleſs ſtate, it ſo nearly imitates the diamond, that even jewellers themſelves are often deceived, it wanting nothing but the hardneſs to render it equal to that gem.

Boet affirms, that he has ſeen one ſet in a gold ring which was ſold for two hundred crowns. They are found in India, Arabia, Armenia, Ethiopia, Cyprus, Germany, Bohemia, and Miſnia; but as they are generally as ſoft as cryſtal, they are not in very great eſteem. The oriental are hardeſt; if they are without ſpots, they are of the greateſt value. They are found of various ſizes, and in various ſhapes, from the bigneſs of a ſmall pea, to an inch and a half in diameter. They are adulterated with maſtick, tinged of a violet colour, placed between two cryſtals; but the Germans do not think it worth while to counterfeit them, becauſe they are pretty common.

AMETHYST, in heraldry, is a term uſed for a purple colour in the coat of a nobleman.

AMIABLE, or AMICABLE *Numbers*, in arithmetic, are ſuch as are equal to the ſum of each other's aliquot parts.

Thus the numbers 284 and 220 are amicable numbers; for the aliquot parts 1, 2, 4, 5, 10, 11, 20, 22, 44, 55, 110, of 220, are together equal to the other number 284; and the aliquot parts 1, 2, 4, 71, 142, of 284, are together equal to 220.

Van Schouten is ſuppoſed to be the firſt who gave this name to ſuch numbers; and ſhews at *Sect.* II. *Miſcellan.* at the end of his *Exercitationes Geometr.* how the above pair of amicable numbers may be found by common algebra, by ſuppoſing one of the numbers to be $4x$, and the other $4yz$, and making an equality between them and their ſeveral aliquot parts. Thus, the aliquot parts of $4x$ are $1, 4, x, 2, 2x$; thoſe of $4yz$ are $1, 2, 4, 4y, 4z, 2y, 2yz, yz, z, y, 2z$: the ſum of the former is $7+3x$, and that of the latter equal to $7+3yz+7y+7z$. Hence theſe equations $7+3x=4yz$, and $7+3yz+7y+7z=4x$, conſequently we have, after due reduction, $\frac{49+21y}{7y-21}=z$, or $z=\frac{7+3y}{y-3}$. In this equation the leaſt value that can be aſſumed for y, muſt be 5, otherwiſe z will be negative; therefore, taking $y=5$, z will become 11, and $4zy=220$, whence we get $4x=284$.

If $16x$ and $16yz$ had been aſſumed for the required numbers, inſtead of the former values $4x$ and $4yz$, then by the ſame ſort of proceſs as before, $16yz$, would have been found equal to 17296, and $16x=18416$, the next pair of amicable numbers, whoſe alternate aliquot parts are 1, 2, 4, 8, 16, 1151, 2302, 4604, 9208, and 1, 2, 4, 8, 16, 23, 46, 47, 92, 94, 184, 188, 368, 376, 752, 1081, 2162, 4324, 8648; their total ſums equal to 17296 and 18416 reſpectively.

It is eaſy to apprehend, from the nature of theſe numbers, that there are but a very few of them, at leaſt, to be ſet down and manageable by us; for 284 and 220 are the two leaſt; and the two next greater are 18416 and 17296.

AMIANTHUS, in natural hiſtory, vulgarly called earth-flax, is a fibrous, flexile, and mineral ſubſtance, compoſed of ſhort and abrupt filaments.

It is a ſtony concrete, of the talky kind, though differing from talc in its external appearance. It is not near ſo bright, or ſo ſmooth and unctuous; and compoſed not of leaves or plates, but of long filaments like flax: it has been ſpun into cloth, and formed into paper, incombuſtible and indeſtructible in the fire.

There are ſome ſorts of amianthus whoſe filaments are rigid and brittle, others more flexible: the firſt are not at all to be ſpun or formed into cloth; and the latter with very great difficulty. This manufacture appears to have been known among the ancients, who, according to Pliny, wrapt the corpſe of the dead in amianthine clothes, to preſerve their aſhes ſeparate from thoſe of the funeral pile; an uſe to which they are ſtill ſaid to be applied among the princes of Tartary. The method of preparation, as deſcribed by Ciampini in the Philoſophical Tranſactions, N°. 273, is as follows: The ſtone is laid to ſoak in warm water, then opened and divided by the hands, that the earthy matter may be waſhed out. This earth is white like chalk, and renders the water thick and milky. The ablution being ſeveral times repeated, the flax-like filaments are collected and dried; they are moſt commodiouſly ſpun with an addition of flax: two or three filaments of the amianthus are eaſily twiſted along with the flaxen-thread, if the operator's to face North America

fingers are kept oiled. The cloth alſo when woven is beſt preſerved by oil from breaking or waſting. On expoſure to the fire, the flax and the oil burn out, and the cloth comes out pure and white. Probably from the diſſipation of ſome extraneous matter of this kind proceeded the diminution of weight which an amianthine napkin ſuffered in the fire, in an experiment made before the Royal Society; for pure amianthus loſes nothing. The ſhorter filaments which ſeparate in waſhing the ſtone, may be made into paper in the common manner.

The proprietor of a forge in ſome part of France, not named, upon taking down his furnaces to repair them, found a great quantity of this ſubſtance at the bottom, which, like the native amianthus, was capable of being manufactured either into incombuſtible linen or paper. Upon a farther enquiry, he diſcovered that both this and the native amianthus is nothing more than calcined iron, deprived of the phlogiſtic, and that uniting the phlogiſtic with this, or the foſſil amianthus, he can reſtore it any time to its primitive ſtate of iron.

AMICITIA, in the feudal cuſtoms, were lands granted to be enjoyed only ſo long as the donor pleaſed.

AMIDSHIPS, amongſt ſeamen, the middle of the ſhip, either with regard to her length or breadth; as, put the helm amidſhips; i. e. at an equal diſtance from both the ſides. She bore down, and her ſtem took us amidſhips, i. e. in or near the middle, between the ſtem and ſtern, or the two ends.

AMIESTIES, a ſpecies of cotton cloths imported from the Eaſt Indies.

AMMI, biſhops weed, in botany, a diſtinct genus of umbelliferous plants, the flower of which is roſaceous, compoſed of heart-like petals; and its fruit a ſmall roundiſh and ſtriated capſule, containing two ſtriated ſeeds, convex on one ſide.

The ſeeds of this plant have been long known in the ſhops as one of the leſſer hot ſeeds, and eſteemed aromatic, aperitive, carminative, and alexipharmic.

AMMOCHRYSOS, in natural hiſtory, the name of a ſtone common in Germany, with gold coloured ſpangles. It is much uſed, after being reduced to powder, to ſtrew over writings.

The word is Greek, and compounded of αμμος, ſand, and χρυσος, gold.

AMMODYTES, the ſand ſerpent, in natural hiſtory, the name of a ſerpent found in different parts of the world, particularly in the torrid zone, and ſo called from its burying itſelf in the ſand.

The word is Greek, and compounded of αμμος, ſand, and δυω, to bury in, or get under.

This ſerpent greatly reſembles the viper, except in its head and jaws, which are much larger. It is about two feet in length, and of a ſandy colour. On the external part of its upper jaw there is an eminence reſembling a wart, whence it has alſo been called the horned ſerpent.

The ammodytes of Ceylon is a very large and dangerous ſerpent, with a mouth full of ſharp teeth. The eyes are large and ſparkling, and the forehead is covered with ſmall round ſcales, ſome of which are yellow, others red, and ſpeckled with black. On each ſide of the eyes are black ſtripes reaching to the neck; but the body, above and below, is of a whitiſh aſh-colour; and on the back are angular ſpots variegated with white and brown. The ſcales that cover the upper part of the body, are placed like net-work, with large meſhes, and the tail is ſpotted with brown, ending in a bony point.

The ammodytes of Surinam is a ſerpent which the negroes have in high eſteem, and they think themſelves very happy if they come into their huts; their colours are ſo many and beautiful, that they ſurpaſs all deſcription.

AMMON, or HAMMON, in mythology, the name of the Egyptian Jupiter, worſhipped under the figure of a ram.

Bacchus, having ſubdued Aſia, and paſſing with his army through the deſarts of Africa, was in great want of water; but Jupiter, his father, aſſuming the ſhape of a ram, led him to a fountain, where he refreſhed himſelf and his army: in requital of which favour, Bacchus built there a temple to Jupiter, under the title of Ammon, from the Greek αμμος, which ſignifies ſand, alluding to the ſandy deſart where it was built.

This is the poetical account: but it is more probable that the Egyptians worſhipped the ſun under this name; for *hammah*, in Hebrew, ſignifies the ſun; or perhaps they meant by it Ham, the ſon of Noah, whoſe poſterity ſettled in Libya.

Cornu AMMONIS, in natural hiſtory; ſee the article CORNU *Ammonis*.

AMMONIACUM, or *Gum* AMMONIACUM, in the materia medica, a concrete gummy-reſinous juice brought from the Eaſt Indies, and generally in large maſſes.

Both the plant which produces ammoniacum, and the place of its production, are unknown. The beſt ammoniacum is compoſed of white, whitiſh, or yellowiſh tears baked into maſſes: the internal parts particularly are whitiſh; by age it becomes more and more yellow and brown. It eaſily ſoftens and becomes tough betwixt the fingers. Chewed, it diſcovers a bitteriſh, glutinous, not diſagreeable, taſte. Its ſmell approaches to that of a mixture of opopanax and galbanum: ſome reſemble it to that of caſtor, others to that of coriander-ſeeds, and others to that of garlic.

It diſſolves almoſt equally in water and ſpirit. Out of an ounce of choice ammoniacum, rectified ſpirit of wine diſſolved ſix drams; water, applied to another ounce, took up ſix drams two ſcruples and a half. From the matter left undiſſolved by ſpirit, water took up five ſcruples and five grains; from that which water left undiſſolved, rectified ſpirit extracted a dram; the indiſſoluble part amounting in the firſt caſe to fifteen grains, in the latter only to half a ſcruple. In diſtillation, ſpirit of wine ariſes unchanged; the diſtilled water has ſomewhat of a ſweetiſh taſte, and ſmells a little of the ammoniacum, but gives no appearance of any eſſential oil.

Ammoniacum is accounted deobſtruent; promotes urine; and, in large doſes, opens the belly. It is given particularly in obſtructions of the breaſt, in cachectic, hydropic, and apoplectic caſes, from a ſcruple to half a dram. It operates more effectually in a liquid form, as that of an emulſion, than in the ſolid one of pills; but is moſt commodiouſly taken in the latter form. It is ſometimes diſſolved in vinegar: externally it reſolves hard ſwellings. It is purified by diſſolving it in vinegar, wine, or water, and ſtraining and inſpiſſating the ſolution.

Sal AMMONIACUM. See SAL-AMMONIACUM.

AMMONITÆ, in natural hiſtory, the ſame with cornu ammonis. See CORNU *Ammonis*.

AMMUNITION, in military affairs, a general name for powder, balls, &c.

AMMUNITION *Bread*, *Shoes*, *&c.* ſuch as are ſerved out to the ſoldiers of an army, garriſon, &c.

AMNESTY, in civil policy, implies an act, whereby two parties at variance mutually promiſe to pardon and bury in oblivion all that is paſt.

But in a more limited ſenſe it ſignifies a pardon granted by a prince to his ſubjects, by which the former promiſes to forget and annul all that is paſt.

The word is formed from the Greek, *αμνηστια*, the name of an edict of this kind publiſhed by Thraſibulus, on his expulſion of the tyrants out of Athens.

AMNIOS, in anatomy, a thin pellucid membrane ſurrounding the fœtus.

It is an interior membrane, contiguous to the exterior one called the chorion, having no veſſels, or at moſt very few; and contains a pellucid glutinous liquor, which flows out upon breaking this membrane at the time of delivery.

AMOMUM *Verum*, true amomum, in the materia medica, a cluſter of round fruits, or ſeed veſſels, of an oriental plant. Each fruit is about the ſize of a middling grape; and contains, under a membranous cover, a number of ſmall rough angular ſeeds, of a blackiſh brown colour on the outſide, and whitiſh within: the ſeeds are lodged in three diſtinct cells, and thoſe in each cell joined cloſely together; ſo that the fruit, on being opened, appears to contain only three ſeeds. Ten or twelve of theſe capſules ſtand together, without pedicles, upon a woody ſtalk about an inch long: each ſingle capſule is ſurrounded with ſix leaves ſet in form of a ſtar; and the part of the ſtalk, void of fruit, is clothed with leafy ſcales. Of the other parts of the plant, we have no certain account.

The ſeeds of amomum are a ſtrong and grateful aromatic, of a quick penetrating fragrant ſmell, ſomewhat like that of lavender, but more agreeable, and of a very warm pungent taſte, approaching to that of camphor. They are ſaid to yield in diſtillation a large portion of a ſubtile eſſential oil. The huſks have the ſame kind of flavour in a lower degree. Theſe ſeeds have long been a ſtranger to this country. They are directed as an ingredient in the theriaca, in which they have been commonly ſupplied by the ſeeds of the amomum vulgare; and the London college, under the name amomum, have now allowed either the verum or vulgare to be taken indifferently. The college of Edinburgh, while they retained that compoſition, employed as a ſuccedaneum to the amomum, a ſpice more approaching to the nature of cloves.

Amomum *Vulgare*, baſtard ſtone parſley, in the materia medica, an umbelliferous plant; very much branched; with a firm ſtalk higher than the branches; deep green, winged, ſerrated, parſnep-like leaves; upright umbels; and ſmall, narrow, oblong, ſtriated, dark browniſh ſeeds, flat on one ſide and convex on the other. It grows wild under moiſt hedges, and by the ſides of ditches; flowers in June and July, and ripens its ſeeds in Auguſt.

The ſeeds of the amomum vulgare have a light agreeable ſmell, and a mild warm aromatic taſte. They have been ſometimes given as carminatives and diuretics, like the other warm ſeeds, and uſually ſubſtituted in the ſhops for thoſe of the amomum verum, from which, however, they are very conſiderably different in quality, as well as in appearance: they are not near ſo hot or pungent, nor is their flavour of the ſame kind.

Theſe ſeeds, infuſed in water, give out very little of their virtue: by boiling, their flavour is ſoon diſſipated, and the liquor becomes diſagreeably bitteriſh: in diſtillation with water they yield a ſmall portion of a yellowiſh eſſential oil, which taſtes and ſmells ſtrongly and agreeably of the ſeeds.

Rectified ſpirit readily extracts their virtue, and, what is pretty ſingular, gains from them a green tincture: the ſpirit, drawn off by diſtillation from the filtered liquor, brings over with it nothing conſiderable of the flavour of the ſeeds: the remaining extract taſtes ſtrongly and ſmells lightly of the amomum, and proves a moderately warm, bitteriſh, not ungrateful, aromatic.

AMPELITES, cannel-coal, in natural hiſtory: ſee the article Cannel-Coal.

AMPHIARTHROSIS, in anatomy, a ſpecies of articulation or juncture of the bones, having a manifeſt motion.

The word is Greek, and compounded of αμφι, about, and αρθρωσις, articulation.

It reſembles the diarthroſis in being moveable, and the ſynarthroſis in its connection. See Diarthrosis, and Synarthrosis.

The pieces which compoſe it have not a particular cartilage belonging to each of them, as in the diarthroſis; but are both united to a common cartilage, which being more or leſs pliable, allows them certain degrees of flexibility, though they cannot ſlide upon each other. By this ſpecies of articulation the bodies of the vertebræ are connected with each other.

AMPHIBIOUS, in natural hiſtory, an epithet applied to ſuch animals as live part of their time on the land, and part in the water.

The word is Greek, αμφιβιος, and compounded of αμφι, both, and βιος, life; as living in two elements.

Linnæus has made a claſs of amphibious animals; the firſt order of which contains the tortoiſe, the frog, the crocodile, the lizard, the ſalamander, the cameleon, the ſcinc, &c. and the ſecond the ſerpents.

AMPHIBLESTROIDES, in anatomy, a name given to one of the tunics or membranes of the eye, generally called the retina. See the article Retina.

The word is Greek, and compounded of αμφιβληςρον, a net, and ειδος, reſemblance; becauſe the ſtructure of that membrane reſembles a net; and hence the Latins call it *retiformis*.

AMPHIBIOLOGY, in grammar, implies the ſame as ambiguity, or that the phraſe is capable of two different interpretations.

The word is Greek, αμφιβολογια, and compounded of αμφι, about, and βαλλω, to throw.

AMPHIBRACHYS, in the Greek and Latin poetry, is the name of a foot conſiſting of three ſyllables, one long and the other two ſhort, the former being in the middle, and the others forming the two extremities.

The word is Greek, and compounded of αμφι, about, and βραχυς, ſhort.

AMPHICTYONS, in antiquity, the deputies ſent from the different ſtates of Greece, to Thermopile, where they met regularly twice a year, in the temple of Ceres, built in a large plain near the river Aſophus. They decided all differences that happened between any of the cities of Greece, and their deciſions were held ſacred and inviolable.

They had their name from Amphictyon III. king of Athens, who firſt eſtabliſhed an aſſembly of Amphictyons, in order to unite the Greeks more firmly together, and render them a terror to the barbarous nations in their neighbourhood.

Acryſius alſo inſtituted a council of Amphictyons on the model of the former; and who met twice a year in the temple of Delphos.

AMPHIDROMIA, a feaſt celebrated by the ancients on the fifth day after the birth of a child.

AMPHIMACER, a foot in ancient Greek and Latin poetry, conſiſting of three ſyllables, of which the firſt and laſt are long, and that in the middle ſhort.

The word is Greek, and compounded of αμφι, about, and μακρος, long.

AMPHIPOLES, in antiquity, the principal magiſtrates of Syracuſe. They were eſtabliſhed by Timoleon in the 109th Olympiad, after the expulſion of the tyrant Dionyſius. They governed Syracuſe for the ſpace of three hundred years; and Diodorus Siculus aſſures us, that they ſubſiſted in his time.

AMPHROSTYLE, in ancient architecture, implied a temple that had four columns in both the fore and hind fronts, which were parallel.

The word is Greek, and compounded of αμφι, about, προ, before, and ςυλος, a column.

AMPHISBÆNA, in natural hiſtory, a kind of ſerpent, found in hot climates, and ſo called becauſe it moves with either end forward.

The word is Greek, and formed from αμφι, about, and βαινω, to go.

AMPHISCII, in geograpby, a name applied to thoſe people who inhabit the torrid zone; becauſe their ſhadows point one part of the year towards the north, and the other towards the ſouth.

The word is Greek, and compounded of αμφι, about, and σκια, a ſhadow,

AMPHITHEATRE, in antiquity, a ſpacious edifice, of a circular or oval form, with a number of riſing ſeats, on which the people ſat to behold the combats of gladiators, wild beaſts, and other ſports.

The word is Greek, and compounded of αμφι, about, and θεατρον, a theatre.

Amphitheatres were originally built of wood; and Statilius Taurus, in the reign of Auguſtus, was the firſt who erected one of ſtone, The loweſt part was called *arena*, from its being generally ſtrewed with ſand, for the conveniency of the combatants; and round the arena were vaults, in which the wild beaſts, appointed for the ſhews, were contained.

Above theſe cells was erected a large circular periſtyle, for accommodating the emperors, ſenators, and other perſons of diſtinction. Over the periſtyle were the rows of benches, which were entered by avenues terminated by gates called vomitoriæ.

Amphitheatre, in gardening, a temple of view, erected on a riſing ground, of a ſemi-circular figure.

They are formed of ever-greens, obſerving always to plant the lower trees in the front, and the taller behind.

They are alſo made of ſlopes on the ſides of hills covered with turf; being formerly conſidered as great ornaments in a garden, but now generally excluded; as the natural ſlope of ſuch hills is much more beautiful than the ſtiff angular ſlopes of theſe amphitheatres.

AMPHITRITE, in mythology, a goddeſs of the ſea, the daughter of Ocean and Doris, and wife of Neptune. She at firſt refuſed the addreſſes of that god, and reſolved to preſerve her virginity; but Neptune ſent a dolphin in ſearch of her, who found her at the foot of Mount Atlas, and perſuaded her to marry the god of the ſea. Two of the Nereides were alſo called by this name.

Amphitrite, in natural hiſtory, is the name of a ſmall naked ſea inſect, of an oblong figure, with only one tentaculum reſembling a piece of thread.

AMPHORA, in antiquity, a liquid meaſure in uſe among the Greeks and Romans; that uſed by the latter contained about ſeven gallons one pint Engliſh wine meaſure; but the Grecian amphora contained one third more.

Amphora was alſo a dry meaſure uſed by the Romans, and contained about three buſhels.

Amphora, among the Venetians, is the largeſt meaſure uſed for liquids, containing about ſixteen quarts.

AMPLIFICATION, in rhetoric; ſee the article Exaggeration.

AMPLITUDE, in aſtronomy, is an arch of the horizon, intercepted between the true eaſt or weſt point thereof, and the center of the ſun, or a ſtar, at its riſing or ſetting; the former is called the eaſtern or ortive, and the latter the weſtern or occiduous amplitude.

The eaſtern and weſtern amplitude are alſo called northern and ſouthern, as they fall in the northern and ſouthern quarters of the horizon.

To find the ſun's or a ſtar's amplitude, either riſing or ſetting, by the globe, ſee Globe.

To find the amplitude trigonometrically, by having the latitude of the place and declination of the ſun given; let H O (plate X. *fig.* 2.) repreſent the horizon, P the north and S the ſouth pole; Æ Q the equator, Z the zenith, and N the nadir, and the primitive circle H P O S a meridian; then will B be the eaſt or weſt point of the horizon: and if C repreſent the center of the ſun, or of a ſtar, at its riſing, the arch B C will be the amplitude required.

Suppoſe the latitude 50° 30′ N. and the ſun's declination 21° 00′; then in the right angled ſpherical triangle B D C, right angled at D, are given the perpendicular D C = the ſun's declination = 21°, and the angle D B C = the arch O Q, = the comp. lat. = 39° 30′ to find the hypothenuſe B C; which will be found by the following proportion.

As the ſine of the angle D B C =	39°, 30′ -	9,803510
To radius — — — —	90°, 00′ -	10,000000
So is the ſin. of D C, the ſun's dec. =	21°, 00′ -	9,554329
To the ſin. of B C, the amp. req. =	34°, 18′ -	9,750819

Magnetical Amplitude is an arch of the horizon contained between the center of the ſun at his riſing or ſetting, and the eaſt or weſt point of the compaſs. It is found by an amplitude or azimuth compaſs, by obſerving the ſun at his riſing or ſetting, and is always equal to the difference between the true amplitude, and the variation of the compaſs.

Amplitude of the range of a projectile, denotes the horizontal line ſubtending the path in which it moves. See Projectile.

Amplitude *Compaſs*, in navigation, an inſtrument more exactly calculated to obſerve the ſun's magnetical amplitude than the common ſea-compaſs. See the article *Amplitude* Compass.

AMPULLA, in antiquity, a round veſſel uſed by the ancients in their baths for containing the oil for anointing their bodies. It alſo ſignified a cup made of glaſs or leather for drinking out of at table.

AMPUTATION, in ſurgery, the operation of cutting off a limb or other part of the body.

Manner of Amputating *a Limb.*—Lay your patient on a table, three feet four inches high, which is much better than a low ſeat, both for ſecuring him ſteady, and giving yourſelf the advantage of operating without ſtooping, which is not only painful but inconvenient in the other ſituation. While one of your aſſiſtants holds the leg, you muſt roll a ſlip of fine rag, half an inch broad, three or four times round it, about four or five inches below the inferior extremity of the patella; this being pinned on is to ſerve as a guide to the knife, which without it, perhaps, would not be directed ſo dextrouſly; the manner of rolling has always been perpendicular to the length of the leg; but having obſerved, that though the amputation at firſt be even, yet afterwards the gaſtrocnemius muſcle, contracting, draws back the inferior part of the ſtump more ſtrongly than the other muſcles can do the reſt of it; I have lately, in order to preſerve the regularity of the cicatrix, allowed for this exceſs of contraction, and made the circular inciſion in ſuch a manner, that the part of the wound which is on the calf of the leg, is farther from the ham than that on the ſhin is from the middle of the patella.

In the mean time, one of your aſſiſtants muſt carry a ſtrong ligature round the thigh, about three or four inches above the patella, which, paſſing through a couple of ſlits in a ſquare piece of leather, he muſt twiſt with a tourniquet, till the artery is ſufficiently compreſſed, to prevent any great effuſion of blood; and, to do it more effectually, he may lay a bolſter of tow or linen under the ligature, upon that part where the artery creeps.

The courſe of the blood being ſtopped, you muſt begin your inciſion juſt below the linen roller, on the under part of the limb, bringing your knife towards you; which, at one ſweep, may cut more than the ſemi-circle: then, beginning your ſecond wound on the upper part, it muſt be continued from the one extremity to the other of the firſt wound, making them but one line. The inciſions muſt be made quite through the membrana adipoſa, as far as the muſcles; then taking off the linen roller, and an aſſiſtant drawing back the ſkin as far as it will go, you make your wound from the edges of it, when drawn back, through the fleſh to the bone, in the ſame manner as you did through the ſkin. Before you ſaw the bones, you muſt cut the ligament between them with the point of your knife; and the aſſiſtant, who holds the leg while it is ſawing, muſt obſerve not to lift it upwards, which would clog the inſtrument.

In amputating below the knee, it is of advantage to ſtand on the inſide of the leg, becauſe the tibia and fibula lie in a poſition to be ſawed at the ſame time, if the inſtrument be applied externally: whereas, if we lay it on the inſide of the leg, the tibia will be divided firſt, and the fibula afterwards; which not only lengthens the operation, but is alſo apt to ſplinter the fibula when it is almoſt ſawed through, unleſs the aſſiſtant be very careful in ſupporting it.

When the leg is taken off, the next regard is to be had to the ſtopping of the blood, which muſt be effectually done before the patient is put to bed, or there will be great danger of bleeding again, when the fever is excited, and the veſſels of the ſtump dilated, both which happen a very little while after the operation. There is no method for this purpoſe ſo ſecure as tying the extremities of the veſſels with a ligature, which, with a crooked needle paſſed twice through the fleſh almoſt round them, will, when the knot is made, neceſſarily incloſe them in the ſtricture; and to diſcover the orifice of a veſſel, your aſſiſtant muſt every time looſen the tourniquet: this is a much better way than uſing the artery forceps, where the veſſels are apt to ſlip away out of the ligature; and as to ſtyptic applications, their want of ſafety is ſo well known now, that the uſe of them, in hæmorrhages from large veſſels, is almoſt univerſally rejected.

It ſometimes happens in a large ſtump, that ten or more veſſels require tying; which done, you muſt apply looſe dry lint to the wound, or, in caſe the ſmall veſſels bleed plentifully, you muſt throw a handful of flour among the lint, which will contribute to the more effectual ſtopping up their orifices. Before you lay on the pledget, you muſt bind the ſtump, and begin to roll from the lower part of the thigh down to the extremity of the ſtump. The uſe of this roller is to keep the ſkin forwards, which, notwithſtanding the ſteps already taken to prevent its falling back, would in ſome meaſure do ſo, unleſs ſuſtained in this manner. The dreſſings may be ſecured by the croſs cloth and gentle bandage ; and the method of treating the wound muſt be the ſame as that for other recent and inciſed wounds. See WOUND.

Before the invention of making the double inciſion I have juſt now deſcribed, the cure of a ſtump was always a work of time ; for by cutting down to the bone at once, and ſawing it directly, the conſequence was, that the ſkin and fleſh withdrew themſelves, and left it protruding out of the wound two or three inches in ſome caſes ; ſo that it rarely happened that an exfoliation did not follow ; which, beſides being tedious, alſo frequently reduced the wound to an habitual ulcer, and at beſt left a pointed ſtump, with a cicatrix ready to fly open upon the leaſt accident ; all which inconveniences are avoided by this new method, and I know not of any objection to it, unleſs that the pain of making the wound is ſuppoſed to be twice as much as in the other, becauſe of the double inciſion ; but when we conſider that we only cut the ſkin once, and the fleſh once, though not in the ſame moment, I fancy, upon reflection, the difference of pain will be thought inconſiderable.

In amputating the thigh, the firſt inciſion is to be made a little more than two inches above the middle of the patella ; after the operation, a roller ſhould be carried round the body, and down the thigh, to ſupport the ſkin and fleſh. This is alſo the moſt proper bandage, as abſceſſes will ſometimes form in the upper part of the thigh, which cannot diſcharge themſelves ſo conveniently with any other, it being almoſt impracticable to roll about the abſceſs, unleſs you begin from the body.

The amputation of the arm and cubit differs ſo little from the foregoing operations, that it will be but a repetition to deſcribe it. However, it muſt be laid down as a rule, to preſerve as much of the limb as poſſible, and, in all amputations of the upper limbs, to place your patient in a chair.

There are, in armies, a great many inſtances of gunſhot wounds of the arm, near the ſcapula, which require amputation at the ſhoulder ; but the apprehenſion of loſing the patients on the ſpot by the hemorrhage, has deterred ſurgeons from undertaking it. I have heard of its having been done once ; but, though it had never been performed, we might learn it is practicable from the caſe of a poor miller, whoſe arm and ſcapula were both torn from his body by a rope which was accidentally twiſted round his wriſt, and ſuddenly drawn up by the mill. The poor man recovered in a few weeks. It is remarkable in this accident, that after fainting, the hemorrhage ſtopped of itſelf, and never bled afreſh, though nothing but lint and turpentine were laid on the great veſſels. In caſe, therefore, of a wound or fracture near the joint, or incurable fiſtulas in the joint, not attended with much caries, I think the operation may be performed ſafely in this manner : The patient's arm being held horizontal, make an inciſion through the membrana adipoſa, from the upper part of the ſhoulder, acroſs the pectoral muſcle down to the arm-pit ; then, turning the knife with its edge upwards, divide that muſcle, and part of the deltoid ; all which may be done without danger of wounding the great veſſels, which will become expoſed by theſe openings ; if they be not, cut ſtill more of the deltoid muſcle, and carry the arm backward ; then with a ſtrong ligature having tied the artery and vein, purſue the circular inciſion through the joint, and carefully divide the veſſels at a conſiderable diſtance below the ligature ; the other ſmall veſſels are to be ſtopped as in other caſes.

In performing this operation, regard ſhould be had to the ſaving as much ſkin as poſſible, and to the ſituation of the proceſſus acromion, which projecting conſiderably beyond the joint, an unwary operator would be apt to cut upon it.

The amputation of the fingers and toes is better performed in their articulation, than by any of the other methods : for this purpoſe a ſtraight knife muſt be uſed, and the inciſion of the ſkin be made not exactly upon the joint, but a little towards the extremity of the fingers, that more of it may be preſerved for the eaſier healing afterwards ; it will alſo facilitate the ſeparation in the joint, when you cut the finger from the metacarpal bone, to make two ſmall longitudinal inciſions on each ſide of it firſt. In theſe amputations there is generally a veſſel or two that require tying, and which often prove troubleſome when the ligature is omitted.

It may happen that the bones of the toes, and part only of the metatarſal bones, are carious, in which caſe the leg need not be cut off, but only ſo much of the foot as is diſordered ; a ſmall ſpring-ſaw is better to divide with here than a large one. When this operation is performed, the heel and remainder of the foot will be of great ſervice, and the wound heal up ſafely, as I have once found by experience. *Sharp's Surgery.*

AMSDORFIANS, in eccleſiaſtical hiſtory, a ſect of proteſtants who appeared in the ſixteenth century, and acquired the name from one Amſdorf their leader.

They maintained that good works were ſo far from being profitable, that they were even pernicious, and obſtacles in the road to ſalvation.

AMULET, a charm or preſervative againſt miſchief, witchcraft, and diſeaſes.

The word is Latin, *amuletum*, which ſignifies the ſame thing.

The ancients of all nations were extremely fond of amulets ; but the preſent philoſophy has pretty well baniſhed theſe and other impoſitions of the ſame kind from the world.

AMYDALES, in anatomy ; ſee the article TONSILS.

AMYGDALUS, the almond-tree. See ALMOND-TREE.

ANA, among phyſicians, denotes an equal quantity of the ingredients that immediately precede it in preſcription.

ANABAPTISTS, in eccleſiaſtical hiſtory, a ſect of proteſtants that ſprung up in Germany about the year 1521, immediately after the reformation of Luther. They at firſt preached up an entire freedom from all ſubjection to the civil power ; but their principal tenet, and that from whence they take their name, conſiſts in re-baptizing all converts to their ſect, and condemning infant-baptiſm.

The word is formed from the Greek, ανα, again, and βαπτιζω, to baptize.

The fanaticiſm of this ſect roſe to an amazing height, and many places ſuffered ſeverely, particularly the town of Munſter, which they ſeized ; and one John of Leyden, the king of this New Jeruſalem, defended himſelf in it as long as poſſible ; but the place was at length taken, and that ringleader of the anabaptiſts put to death in the year 1536. The anabaptiſts of Frieſland and Holland condemned the ſeditious behaviour of their brethren at Munſter ; though they themſelves raiſed ſeveral commotions under the conduct of one Mennon. They were, however, ſome time after pretty well cured of their principal errors ; ſo that they no longer pretended to inſpiration ; no longer oppoſed magiſtrates ; nor preached up a freedom from all ſubjections, a community of goods, and the like.

They ſupported their principal tenet from the following words of our Saviour, “ He that believeth, and is “ baptized, ſhall be ſaved.” Now as adults alone are capable of believing, they argued, that adults only were fit to be baptized. Calvin, and other writers againſt them, had recourſe to the practice of the primitive church, which is clearly on the ſide of infant baptiſm. But ſome drew an argument againſt them from the Scripture, which tells us that children are capable of the kingdom of heaven, and at the ſame time aſſures us, that except a man be baptized he cannot enter into the kingdom of God : ſince therefore, ſay they, children are capable of entering into the kingdom of God, they are alſo qualified for being baptized.

It will be neceſſary to add, that the anabaptiſts of England are not included in the above deſcription ; for, except their rejecting infant baptiſm, they differ very little from the other proteſtant diſſenters, as may be ſeen in a Confeſſion of Faith, publiſhed in the year 1689, by the repreſentatives of their congregation.

ANABASII, in antiquity, were couriers who were ſent on horſeback, or in chariots, with diſpatches of importance.

The word is Greek, and derived from αναϐαινω, to mount.

ANABIBAZON, in aſtronomy, the Arabic name for the Dragon's tail, or ſouthern node of the moon. See NODE.

ANACALYPTERIA, in antiquity, were feſtivals obſerved among the Greeks on the day when the bride was permitted to lay aſide her veil, and appear in public.

The word is Greek, and derived from ανακαλυπτω, to uncover.

ANACAMPSEROS, *Orpine*, *Live-ever*, or *Roſe-root*, in botany, the name of a plant, whoſe root conſiſts of ſeveral white fleſhy tubercles. Its ſtalks are ſolid, upright and round, divided into a few branches, about a foot and a half in height, on which are many fleſhy, thick, juicy leaves, like purſlain or houſe-leek, of a bluiſh green colour with a reddiſh caſt. The flowers are roſaceous, placed on the top of the ſtalks in umbels, and of a reddiſh colour, with five petals, and ſeveral ſmall ſtamina. A piſtil ariſes from the flower-cup, which turns into a fruit, conſiſting of five capſulæ, collecting as it were into a head, which are full of hard ſeeds.

Orpine is now never given inwardly, and but ſeldom employed outwardly, though it is ſaid to heal freſh wounds, and cleanſe ulcers. The juice is, however, commanded by Hoffman againſt ulcers of the womb.

ANACAMPTIC, an epithet applied to ſounds produced by reflection, and particularly to echos. See ECHO.

The word is Greek, and compounded of ανα, again, and καμπτω, to turn.

They alſo, by analogy, apply the term anacamptic to that part of optics which relates to reflection, now called catoptrics. See CATOPTRICS.

ANACARDIUM, the name of two ſpecies of trees, diſtinguiſhed by the epithets *occidentale* and *orientale*. They are both of the claſs of the *Pruniferæ* of Mr. Ray.

ANACARDIUM *Occidentale* is the fruit of the acajou or caſhew-nut tree. See the article ACAJOU.

ANACARDIUM *Orientale* is the fruit of a large tree found only in the Eaſt Indies. The fruit, or nut, commonly called the Malacca bean, is of a moderately large ſize, of a ſhining black colour, in the ſhape of a heart flattened, of a very thick pedicle, occupying almoſt the whole baſe. The kernel is covered by two tough rinds, between which is lodged a fungous ſubſtance, containing in its cells an extremely acrid matter in a liquid form, while the nut is freſh, but grows dry by long keeping. It is uſed in the ſame intentions with the acajou. See ACAJOU.

ANACATHARSIS, among phyſicians, implies a diſcharge of noxious humours, either by vomit or by ſpitting.

The word is Greek, and derived from ανακαθαιρομαι, to purge upwards.

ANACATHARTICS, medicines that promote an anacatharſis.

ANACEPHALÆOSIS, in rhetoric, a recapitulation of the heads of a diſcourſe. See RECAPITULATION.

The word is Greek, and compounded of ανα, again, and κεφαλη, a head or chief point.

ANACHORETS, or ANCHORETS, in eccleſiaſtical hiſtory, a ſort of monks in the primitive Chriſtian church; ſo called from their retiring from ſociety, and living in private cells in the wilderneſs. Such were Paul and Anthony, and Hilarion, the firſt founders of the monaſtic life in Egypt and Paleſtine. Some of them lived in caves, as St. Chryſoſtom tells us the monks of Mount Caſius, near Antioch, did; and others in little tents or cells. When many of theſe were placed together in the ſame wilderneſs, at ſome diſtance from one another, they were all called by one common name, Laura, which, as Evagrius informs us, differed from a cænobium, or community, in this, that a laura conſiſted of many cells, divided from each other, where every monk provided for himſelf; but a cænobium was but one habitation, where the monks lived in ſociety, and had all things in common.

The word is formed from the Greek, αναχωρεω, to retire into a ſolitary region.

ANACHRONISM, an error in chronology, whereby an event is placed more early than it really happened; but it is often uſed to imply any chronological miſtake.

The word is formed from the Greek, ανα, before, and χρονος, time.

ANACLASTICS, that part of optics which conſiders the refraction of light, and commonly called dioptrics. See DIOPTRICS.

The word is formed from the Greek, ανα, again, or backward, and κλαζω, to break.

ANACLETERIA, a ſolemn feaſt, celebrated by the ancients on the day their kings or princes came of age, and aſſumed the reins of government; on which occaſion they made a ſolemn declaration to their people.

The word is formed from the Greek, ανα, and καλεω, to appeal.

ANACREONTIC *Verſe*, in ancient poetry, a kind of verſe ſo called from its being greatly uſed, if not invented, by the poet Anacreon. It conſiſts of three feet and a half, uſually ſpondees and iambuſes, and ſometimes of anapeſts. The following verſe of Horace is of this kind:

Lydia dic per omnes.

ANADIPLOSIS, in rhetoric and poetry, implies a repetition of the laſt word of a line, or cloſe of a ſentence, in the beginning of the next. As the following verſes of Virgil:

Sit Tityrus, Orpheus,
Orpheus in ſylvis, &c.

The word is Greek, and compounded of ανα, and διπλοω, to double, or repeat.

ANADIPLOSIS, among phyſicians, implies the return of the cold fit in a ſemi-tertian ague, before the fit is entirely ended.

ANADROMOUS, an epithet applied, by naturaliſts, to ſuch fiſh as go at ſtated ſeaſons from the freſh water into the ſea, and afterwards return again to the rivers.

The word is formed from the Greek, αναδρομη, returning back.

ANAGALLIS, *Pimpernel*, in botany, the name of two ſpecies of plants reſembling chickweed, and diſtinguiſhed by the epithets *mas* and *fœmina*.

ANAGALLIS *Mas*, male pimpernel, has a white ſingle root, with a few fibres. Its ſtalks are ſo weak that they lie on the ground, about nine inches in length, ſquare and ſmooth, and the leaves placed by pairs, and ſometimes three at a time oppoſite to each other; but they have no pedicles. The lower ſurface is ſpotted with blackiſh red ſpots; and the flower conſiſts of one leaf, divided into five ſharp ſegments, of a purpliſh red colour, with purple ſtamina, on which are yellow heads. The flower-cup is alſo divided into five parts, from which a piſtil ariſes fixed in the middle of the flower like a nail, and finally becomes a fruit, or globous ſhell, incloſing many angulous wrinkled ſeeds. This is one of the ſleeping plants, or thoſe whoſe flowers open about eight o'clock in the morning, and cloſe again ſoon after noon.

ANAGALLIS *Fœmina*, female pimpernel, differs only from the former in the colour of the flower, which is blue, and in being more ſcarce than the former, which is common in our corn-fields. The male pimpernel is uſed as a ſallad and a pot-herb in many parts of England; though it is by ſome recommended as an excellent medicine againſt madneſs and the epilepſy, provided four ounces of the juice be given thrice a day; but it is not now depended upon for any ſuch purpoſe.

ANAGOGY, among eccleſiaſtical writers, implies the elevation of the ſoul to things celeſtial and eternal.

The word is Greek, αναγωγη, and compounded of ανα, upward, and αγωγη, from αγω, to draw.

ANAGRAM, a tranſpoſition of the letters of ſome name, whereby a new word is formed from the ſame letters, either to the advantage or diſadvantage of the perſon or thing to which the name belongs.

The word is formed from the Greek, ανα, and γραμμα, a letter.

ANAGRAMMATIST, a compoſer of anagrams.

ANAGORIS, in botany; ſee the article BEAN-TREFOIL.

ANAITIS, in mythology, a pagan goddeſs particularly worſhipped by the Armenians. The greateſt men in the country dedicated their daughters to her ſervice, who thought it an honour to proſtitute themſelves to all thoſe who came to ſacrifice to this falſe deity; after which they were eagerly courted in marriage, as being thought to have acquired an extraordinary ſanctity thereby. Upon the feſtival of this idol, the men and women met in crouds together, and intoxicated themſelves with wine. The reaſon of the inſtitution of the feſtival was this: Cyrus having undertaken an expedition againſt the Sacæ, and being beaten, fled with his army; but afterwards encamping in the place where he had left his baggage, he refreſhed his army, and then counterfeited a flight. The Sacæ, purſuing him, and finding the enemy's camp deſerted, but repleniſhed with wine and proviſions, eat and drank till they had quite intoxicated themſelves. Cyrus returning, ſlew them all, and conſecrated that day to the goddeſs.

ANALECTA, in matters of literature, implies a collection of ſmall pieces of compoſitions, as eſſays, remarks, &c.

The word is Greek, and derived from *αναλεγω*, to collect or gather together.

ANALEMMA, a very ancient aſtronomical inſtrument, as appears by its having been treated of by Ptolemy himſelf, in a peculiar work, which was afterwards publiſhed with a commentary upon it by Frederic Commadine. The conſtruction of this inſtrument, which conſiſts of an orthographic projection of the ſphere upon the plane of the meridian, together with a moveable horizon and index, may be ſeen in ſeveral authors, as in Agulonius's and Taquit's Optics, Witty on the Sphere, Deſchale's Mundi Mathem. &c.

Its uſe is for finding the time of the ſun's riſing and ſetting, the length of the longeſt day in any latitude, and the hour of the day.

The analemma is alſo of uſe among dialliſts, for delineating the various ſorts of furniture upon ſolar dials. See PROJECTION of the ſphere, and DIALLING.

ANALEPSIS, in the healing art, implies the augmentation or nutrition of an emaciated body.

The word is Greek, and derived from *αναλαμβανω*, to repair.

ANALEPTICS, in pharmacy, ſuch medicines as are proper for nouriſhing the body when weakened.

ANALOGICAL, ſomething belonging to, or partaking of the nature of analogy. Thus an analogical ſyllogiſm is that which is founded on the analogy between the premiſes.

ANALOGY, a certain relation ſubſiſting between two or more things, which in other reſpects are entirely different.

The word is Greek, *αναλογια*, and compounded of *ανα* and *λογος*, ratio, or reaſon.

ANALOGY, among mathematicians, ſignifies proportion, or a ſimilitude of ratios. See the articles PROPORTION and RATIO.

ANALOGY, in grammar, is the correſpondence which a word or phraſe has to the genius and received forms of a language.

ANALYSIS, in a general ſenſe, implies the reſolution of ſomething compounded into its original and conſtituent parts.

The word is Greek, and derived from *αναλυω*, to reſolve.

ANALYSIS, in mathematics, is properly the method of reſolving problems by means of algebraical equations, whence we often find that theſe two words *analyſis* and *algebra* are uſed as ſynonymous.

Analyſis, under its preſent improvements, muſt be allowed the apex or height of all human learning; it is this method which furniſhes us with the moſt perfect examples of the art of reaſoning, gives the mind an uncommon readineſs at deducing and diſcovering, from a few data, things unknown; and by uſing ſigns for ideas, preſents things to the imagination, which otherwiſe ſeemed out of its ſphere: by this, geometrical demonſtrations may be greatly abridged, and a long ſeries of argumentations, wherein the mind cannot without the utmoſt effort and attention diſcover the connection of ideas, are hereby converted into ſenſible ſigns, and the ſeveral operations required therein, effected by the combination of thoſe ſigns. But, what is more extraordinary, by means of this art, a number of truths are frequently expreſſed by a ſingle line, which in the common way of explaining and demonſtrating things would fill whole volumes. Thus, by mere contemplation of one ſingle line, whole ſciences may ſometimes be learnt in a few minutes time, which otherwiſe could ſcarce be attained in many years.

ANALYSIS is divided, with regard to its object, into that of *finites*, and *infinites*.

ANALYSIS *of finite Quantities*, is what we otherwiſe call ſpecious arithmetic or algebra. See ALGEBRA.

ANALYSIS *of Infinites*, called alſo the *New* ANALYSIS, is particularly uſed for the method of fluxions, or the differential calculus. See FLUXIONS.

ANALYSIS, in logic, ſignifies the method of tracing things backwards to their ſource, and of reſolving knowledge into its original principles.

This is alſo called the method of reſolution, and ſtands oppoſed to the ſynthetic method, or that of compoſition.

The art of logical analyſis conſiſts principally in combining our perceptions, claſſing them together with addreſs, and contriving proper expreſſions for conveying our thoughts and repreſenting their ſeveral diviſions, claſſes, and relations.

ANALYSIS, in rhetoric, denotes the ſtripping a diſcourſe of all its gaudy dreſs of tropes and figures; or, ſhewing what uſe the orator has made of theſe decorations, in order to embelliſh and ſet off every part of his oration to the beſt advantage.

ANALYSIS, in chemiſtry, implies the decompoſing mixed bodies, or ſeparating their component principles, in order to obtain each of them unmixed with the other.

The method moſt commonly uſed in the decompoſition of bodies, is by applying to them ſucceſſive degrees of heat, from the gentleſt to the moſt violent, in appropriated veſſels, ſo contrived as to collect what exhales from them. By this means the principles are gradually ſeparated from each other; the moſt volatile riſe firſt, and the reſt follow in order, as they come to be acted on by the proper degree of heat: and this is called diſtillation.

But it being obſerved that fire, applied to the decompoſition of bodies, moſt commonly alters their ſecondary principles very ſenſibly, by combining them in a different manner with each other, or even partly decompoſing them, and reducing them to their primitive principles; other means have been uſed to ſeparate thoſe principles without the help of fire.

With this view the mixts to be decompoſited are forcibly compreſſed, in order to ſqueeze out of them all ſuch parts of their ſubſtance as they will by this means part with; or elſe thoſe mixts are for a long time triturated, either along with water, which carries off all their ſaline and ſaponaceous contents, or with ſolvents, ſuch as ardent ſpirits, capable of taking up every thing in them that is of an oily or reſinous nature.

ANALYSIS *of Vegetable Subſtances*.—The principles already mentioned are the only ones that can be obtained from any plant without the help of fire; but by the aſſiſtance of that medium we are enabled to analyſe it more completely in the following manner.

A plant being expoſed to a very gentle heat in a diſtilling veſſel, ſet in balneum mariæ, yields a water which retains its perfect ſmell. This water is, by ſome chemiſts, and particularly the illuſtrious Boerhaave, called the ſpiritus rector. The nature of this odoriferous part of plants is not yet thoroughly known; becauſe it is ſo very volatile, that it is difficult to ſubject it to the experiments neceſſary for diſcovering its properties.

If, inſtead of diſtilling the plant in balneum mariæ, it be diſtilled over a naked fire, with the precaution of putting a quantity of water into the diſtilling veſſel along with it, to prevent its ſuffering a greater heat than that of boiling water, all the eſſential oil contained in that plant will riſe together with the above water: and as no eſſential oil can be extracted after the ſpiritus rector has been drawn off, there is reaſon to think that the volatility of theſe oils is owing to that ſpirit.

The heat of boiling water is alſo ſufficient to ſeparate from vegetable bodies the fat oils they contain; but this muſt be done by decoction only, not by diſtillation; becauſe, though theſe oils will ſwim on water, yet they will not riſe in vapours without a greater degree of heat.

When the eſſential oil is come over, if the plant be expoſed to a naked fire without the addition of water, and the heat be increaſed a little, a phlegm will riſe that gradually grows acid; after which, if the heat be increaſed as occaſion requires, there will come over a thicker and heavier oil; from ſome a volatile alkali, and laſt of all, a very thick, black, empyreumatic oil.

When nothing more riſes with the ſtrongeſt degree of heat, there remains of the plant a mere coal only, called the caput mortuum, or terra damnata. This coal, when burnt, falls into aſhes, which, being lixiviated with water, give a fixed alkali.

It is obſervable that in the diſtillation of plants, which yield an acid and a volatile alkali, theſe two ſalts are often found quite diſtinct and ſeparate in the ſame receiver; which ſeems very extraordinary, conſidering that they are naturally diſpoſed to unite, and have a great affinity with one another. The reaſon of this phenomenon is, that they are both combined with much oil, which embarraſſes them ſo that they cannot unite to form a neutral ſalt, as they would not fail to do were it not for that impediment.

All vegetables, except ſuch as yield a great deal of volatile alkali, being burnt in an open fire, and ſo as to flame, leave in their aſhes a large quantity of an acrid, cauſtic, fixed alkali. But if care be taken to ſmother them, ſo as to prevent their flaming while they burn, by covering them with ſomething that may continually beat down again what exhales, the ſalt obtained from their aſhes will be much leſs acrid and cauſtic; the cauſe whereof is, that ſome part of the acid and oil of the plant being detained in the burning, and ſtopped from being diſſipated by the fire, combines with its alkali. Theſe ſalts cryſtallize, and being much milder than the common fixed alkalies, may be uſed in medicine, and taken internally. They are called Tachenius's ſalts, becauſe invented by that chymiſt.

ANALYSIS *of Animal Subſtances.* — Succulent animal ſubſtances, ſuch as new-killed fleſh, yield by expreſſion a juice or liquid, which is no other than the phlegm, replete with all the principles of the animal body, except the earth, of which it contains but little. The hard or dry parts, ſuch as the horns, bones, &c. yield a ſimilar juice, by boiling them in water. Theſe juices become thick, like a glue or jelly, when their watery parts are evaporated; and in this ſtate they are true extracts of animal matters. Theſe juices afford no cryſtals of eſſential ſalt, like thoſe obtained from vegetables, and ſhew no ſign either of an acid or an alkali.

Great part of the oil which is in the fleſh of animals may be eaſily ſeparated without the help of fire; for it lies in a manner by itſelf: it is commonly in a concrete form, and is called fat. This oil ſomewhat reſembles the fat oils of vegetables; for like them it is mild, unctuous, indiſſoluble in ſpirit of wine, and is ſubtilized and attenuated by the action of fire. But there is not in animals, as in vegetables, any light, eſſential oil, which riſes with the heat of boiling water; ſo that, properly ſpeaking, animals contain but one ſort of oil.

Few animal ſubſtances yield a perceptible acid. Ants and bees are almoſt the only ones from which any can be obtained; and, indeed, the quantity which they yield is very ſmall, as the acid itſelf is extremely weak.

The reaſon is, that as animals do not draw their nouriſhment immediately from the earth, but feed wholly either on vegetables or on the fleſh of other animals, the mineral acids, which have already undergone a great change, by the union contracted between them and the oily matters of the vegetable kingdom, enter into a cloſer union and combination with theſe oily parts, while they are paſſing through the organs and ſtrainers of animals, whereby their properties are deſtroyed, or at leaſt ſo impaired that they are no longer ſenſible.

Animal matters yield in diſtillation, firſt a phlegm, and then, on encreaſing the fire, a pretty clear oil, which gradually becomes thicker, blacker, more fetid, and empyreumatic. It is accompanied with a great deal of volatile alkali; and, if the fire be raiſed and kept up till nothing more comes over, there will remain in the diſtilling veſſel a coal, like that of vegetables, except, that when it is reduced to aſhes, no fixed alkali, or at leaſt very little, can be obtained from them, as from the aſhes of vegetables. This ariſes from hence that, as we ſaid before, the ſaline principle in animals being more intimately united with the oil than it is in plants, and being conſequently more attenuated and ſubtilized, is too volatile to enter into the combination of a fixed alkali; on the contrary, it is more diſpoſed to join in forming a volatile alkali, which on this occaſion does not riſe till after the oil, and therefore muſt certainly be the production of the fire. It muſt be obſerved, that all we have hitherto ſaid concerning the analyſis of bodies muſt be underſtood of ſuch matters only as have not undergone any ſort of fermentation.

ANALYSIS *of Mineral Subſtances.* — Minerals differ greatly from vegetables, and from animals; they are not near ſo complex as thoſe organized bodies, and their principles are much more ſimple: whence it follows, that theſe principles are much more cloſely connected, and that they cannot be ſeparated without the help of fire, which, not having on their parts the ſame action and the ſame power as on organized bodies, hath not the ſame ill effect on them.

Theſe bodies are compound maſſes or combinations of ſeveral bodies; that is, metallic ſubſtances as they are found in the bowels of the earth, united with ſeveral ſorts of ſand, ſtones, earth, ſemi-metals, ſulphur, &c. When the metallic matter is combined with other matters, in ſuch a proportion to the reſt that it may be ſeparated from them with advantage and profit, theſe compounds are called ores; when the caſe is otherwiſe, they are called pyrites and marcaſites; eſpecially if ſulphur or arſenic be predominant therein, which often happens. See the articles ORES and ASSAYING.

ANALYSIS, among grammarians, ſignifies the explaining the etymology, conſtruction, and other properties of words.

ANALYSIS is alſo uſed to imply a brief but methodical illuſtration of the principles of a ſcience; in which ſenſe it ſignifies the ſame with ſynopſis.

ANALYSIS likewiſe denotes a table of the principal heads of a continued diſcourſe, diſpoſed in their proper order.

ANALYST, a perſon who uſes the analytic, or algebraical method of reſolving problems.

ANALYTIC, or ANALYTICAL, ſomething that belongs to, or partakes of, the nature of analyſis.

Thus we ſay, an analytical demonſtration, analytical proceſs, analytical table or ſcheme, analytical method of inveſtigation, &c.

The analytic method ſtands oppoſed to the ſynthetic. In natural philoſophy, as in mathematics, the inveſtigation of difficult things by the analytic method ought to precede the method of compoſition. This analyſis conſiſts in making experiments and obſervations, and in drawing general concluſions therefrom by induction; and admitting of no objections againſt the concluſions, but ſuch as are drawn from experiments, and other certain truths: and though the reaſoning from experiments and obſervations by induction be no demonſtration of general concluſions, yet it is the beſt method of reaſoning which the nature of things admits of; and may be eſteemed ſo much the ſtronger, as the induction is more general: and, if no exception occur from phœnomena, the concluſion may be pronounced general By this way of analyſis, we may proceed from compounds to their ingredients; from motions to the forces producing them; and in general from effects to their cauſes, and from particular cauſes to more general ones, until we arrive at thoſe which are the moſt general. This is the analytic method, according to the illuſtrious Newton.

The ſynthetic method conſiſts in aſſuming the cauſes diſcovered and received as principles, and by them explaining the phœnomena proceeding from them, and proving the explanations. See SYNTHESIS.

ANALYTICS, *Analytica*, the ſcience and uſe of analyſis. The great advantage of the modern mathematics above the ancient is in point of analytics.

Pappus in the preface to his ſeventh book of Mathematical Collections, enumerates the authors on the ancient analytics, being Euclid, in his *Data* and *Poriſmata*; Apollonius, *de Sectione Rationis*, and in his *Conics*; Ariſtœus, *de Locis Solidis*; and Eratoſthenes, *de Mediis Proportionalibus*. But the ancient analytics were very different from the modern.

To the modern analytics principally belongs algebra, an hiſtorical account of which, with the ſeveral authors thereon, ſee under the article ALGEBRA.

The chief writers upon the analyſis of infinites are its inventor, Sir Iſaac Newton, in his *Analyſis per Quantitatum Series, Fluxiones et Differentias, cum enumeratione linearum tertii ordinis*; and in his excellent treatiſe *de Quadratura Curvarum*: Leibnitz, in his *Acta Eruditorum*, an. 1684. The marquis de l'Hoſpital, in his *Analyſe des infiniment petites*, 1696. Carre, in his *Methode pour la meſure des ſurfaces, la dimenſion des Solides, &c. par l'application du calcul integral*, 1700. G. Manfredi, *de conſtructione Equationum differentialium, primi gradus*, 1707. Nic. Mercator, in *Logarithmotechnia*, 1668. Cheyne, in *Methodus Fluxionum inverſa*, 1703. Craig, in *Methodus figurarum lineis rectis et curvis comprehenſarum Quadraturas determinandi*, 1685; and *De Quadraturis figurarum curvilinearum et locis, &c.* 1693. David Gregory, in *Exercitatio Geometrica de dimenſione figurarum*, 1684; and Nieuwentiit, in *Conſiderationes circa Analyſeos ad quantitates infinitè parvas applicatæ, principia*, 1695. To theſe we may add the works of thoſe celebrated authors, Cotes, Maclaurin, Robins and Simpſon.

ANAMELECH, an idol of the Sepharvaites, who are ſaid in Scripture, to have burned their children in honour of Adrammelech and Anamelech.

Theſe idols probably ſignified the ſun and moon. Some of the rabbins repreſent Anamelech under the figure of a mule; others under that of a quail or pheaſant.

ANAMNESTICS, among the profeſſors of the healing art, imply the ſigns by which the preſent ſtate of the body is indicated, in contradiſtinction to prognoſtics.

The word is Greek, and derived from *αναμναομαι*, to remember.

ANAMORPHOSIS, in perſpective painting, a monſtrous projection or repreſentation of an image on a plane or curve ſurface, which, beheld at a proper diſtance, ſhall appear regular and in proportion.

The word is Greek, and derived from *αναμορφοω*, to reform, or bring into a new ſhape.

To delineate an anamorphoſis upon a plane. — Draw the ſquare A B C D, (plate VII. *fig.* 4.) of a bigneſs at pleaſure, and ſubdivide it into a number of little ſquares. In this ſquare, called the craticular prototype, let the image to be repreſented deformed, be drawn; then draw the line *a b* (*fig.* 5.) equal to A B, and divide it into the ſame number of equal parts as the ſide of the prototype A B; erect the perpendicular E V in the middle of *a b*, ſo much the longer as the deformity of the image is to be greater. Draw V S perpendicular to E V, ſo much the ſhorter, as you would have the image appear more deformed. From each point of diviſion draw ſtraight lines to V, and join the points *a* and S, by the right line *a* S. Through the points *d e f g*, draw right lines parallel to *a b*, then will *a b c d* be the ſpace in which the monſtrous projection is to be delineated; this ſpace is called the craticular ectype. Laſtly, in every areola, or ſmall trapezium, of the ſpace *a b c d*, draw what appears delineated in the correſpondent areola of the ſquare A B C D; and thus you will obtain a deformed image, which will appear in juſt proportion to an eye diſtant from it the length F V, and raiſed above its height V S.

An image may be deformed mechanically, if you place it, having little holes made here and there in it with a needle, againſt a candle, and obſerve where the rays going through theſe holes, fall on a plane or curve ſurface; for they will give the correſponding points of the image to be deformed.

ANANAS, the pine-apple, in botany, a genus of plants, whoſe flower conſiſts of one funnel-ſhaped leaf, divided into three parts, which afterwards become a fleſhy fruit, full of juice; the ſeeds of which are very ſmall, and almoſt kidney-ſhaped.

Tournefort has enumerated three, and Mr. Miller ſix, ſpecies of this plant.

The pine-apple, ſo called from its reſembling the cones of the European pine-tree, is a native of the torrid zone; but has for ſome years been cultivated here in tolerable perfection. The plant that produces it nearly reſembles the aloe, except that the leaves of the pine-apple are much thinner, longer, and moſt of them near the ground ſtand in a horizontal poſition; but as they approach nearer the fruit, diminiſh in length, and become leſs expanded. The plant, in its native climate, ſeldom grows to above three feet in height, and terminates in a flower reſembling a lily, but of ſo elegant a crimſon as to dazzle the eye. The pine-apple makes its firſt appearance in the center of the flower, about the ſize of a nut; and as this increaſes, the luſtre of the flower fades, and the leaves expand themſelves to make room for it, and ſerve it at once for a baſe and ornament. On the top of the apple itſelf is a crown or tuft of leaves, like thoſe of the plant, and of a very lively blue-green colour. This crown grows in proportion with the fruit, till both have attained their utmoſt magnitude. As ſoon as this happens the fruit begins to ripen, and its green changes into a bright ſtraw-colour; during this alteration of colour, the fruit exhales ſuch a fragrancy as to diſcover it, tho' concealed from ſight. While it continues to grow, it ſhoots out on all ſides, little thorns or prickles, which, as it approaches towards maturity, dry and ſoften, ſo that the fruit is gathered without the leaſt inconvenience.

The ſingularities that concenter in this product of nature cannot fail of ſtriking a contemplative mind with admiration. The crown, which formed a kind of apex, while growing, becomes itſelf a new plant; and the ſtem, after the fruit is cut, dies away, as if ſatisfied with having anſwered the intention of nature in ſuch a production; but the roots ſhoot forth freſh ſtalks, or ſuckers, for the farther increaſe of ſo valuable a ſpecies.

Theſe plants are propagated by planting the crowns which grow on the fruit, or the ſuckers, which are produced either from the plants, or under the fruit, either of which I have found to be equally good, although, by ſome perſons, the crown is thought preferable to the ſuckers, as ſuppoſing it will produce fruit ſooner than the ſuckers, which is certainly a miſtake; for by conſtant experience I find the ſuckers (if equally ſtrong) will fruit as ſoon, and produce as large fruit as the crowns.

The ſuckers and crowns muſt be laid to dry in a warm place for four or five days, or more (according to the moiſture of the part which adhered to the old plant or fruit) for, if they are immediately planted, they will rot. The certain rule of judging when they are fit to plant, is by obſerving if the bottom is healed over, and become hard; for, if the ſuckers are drawn off carefully from the old plants, they will have a hard ſkin over the lower part; ſo need not lie ſo long as thoſe which by accident may have been broken. But whenever a crown is taken from the fruit, or the ſuckers from the old plants, they ſhould be immediately diveſted of their bottom-leaves, ſo high as to allow depth for their planting; ſo that they may be thoroughly dry and healed in every part, leſt, when they receive heat and moiſture, they ſhould periſh, which often happens when this method is not purſued. If theſe ſuckers or crowns are taken off late in the autumn, or during the winter, or early in the ſpring, they ſhould be laid in a dry place in the ſtove, for a fortnight or three weeks before they are planted; but in the ſummer-ſeaſon they will be fit for planting in three or four days.

As to the earth in which theſe ſhould be planted, if you have a rich good kitchen garden mould, not too heavy, ſo as to detain the moiſture too long, nor over light and ſandy, it will be very proper for them without any mixture: but where this is wanting, you ſhould procure ſome freſh earth from a good paſture, which ſhould be mixed with about a third part of rotten neats-dung, or the dung of an old melon or cucumber-bed, which is well conſumed. Theſe ſhould be mixed ſix or eight months at leaſt before they are uſed; but if it be a year it will be better; and ſhould be often turned, that their parts may be the better united, as alſo the clods well broken. This earth ſhould not be ſcreened very fine; for, if you only clear it of the great ſtones, it will be better for the plants than when it is made too fine. You ſhould always avoid mixing any ſand with the earth, unleſs it be extremely ſtiff; and then it will be neceſſary to have it mixed at leaſt ſix months or a year before it is uſed; and it muſt be frequently turned, that the ſand may be incorporated in the earth, ſo as to divide its parts: but you ſhould not put more than a ſixth part of ſand; for too much ſand is very injurious to theſe plants.

In the ſummer ſeaſon, when the weather is warm, theſe plants muſt be frequently watered; but you ſhould not give them large quantities at a time. You muſt alſo be very careful that the moiſture is not detained in the pots by the holes being ſtopped; for that will ſoon deſtroy the plants. If the ſeaſon is warm, they ſhould be watered every other day; but in a cool ſeaſon, twice a week will be often enough: and during the ſummer ſeaſon, you ſhould once a week water them gently all over their leaves, which will waſh the filth off them, and thereby greatly promote the growth of the plants. There are ſome perſons who frequently ſhift theſe plants from pot to pot: but this is by no means to be practiſed by thoſe who propoſe to have large well-flavoured fruit; for unleſs the pots be filled with the roots, by the time the plants begin to ſhew their fruit, they commonly produce ſmall fruit, which have generally large crowns on them; ſo that the plants will not require to be new-potted oftener than twice in a ſeaſon: the firſt time ſhould be about the end of April, when the ſuckers and crowns of the former year's fruit (which remained all the winter in thoſe pots in which they were firſt planted) ſhould be ſhifted into larger pots; i. e. thoſe which were in halfpenny or three-farthing pots, ſhould be put into penny, or at moſt three half-penny pots, according to the ſize of the plants; for you muſt be very careful not to overpot them, nothing being more prejudicial to theſe plants. The ſecond time for ſhifting them is towards the latter end of Auguſt, or the beginning of September, when you ſhould ſhift thoſe plants which are of a proper ſize for fruiting the following ſpring into two-penny pots, which are full large enough for any of thoſe plants. At each of theſe times of ſhifting the plants, the bark-bed ſhould be ſtirred up, and ſome new bark added, to raiſe the bed up to the height it was at firſt made; and when the pots are plunged again into the bark-bed, the plants ſhould be watered gently all over their leaves, to waſh off the filth, and to ſettle the earth to the roots of the plants. If the bark-bed be well ſtirred, and a quantity of good freſh bark added to the bed, at this latter ſhifting, it will be of great ſervice to the plants; and they may remain in the tan until the beginning of November, or ſometimes later, according to the mildneſs of the ſeaſon, and will not require any fire before that time. During the winter ſeaſon theſe plants will not require to be watered oftener than every third or fourth day, according as you find the earth in the pots to dry: nor ſhould you give them too much at a time; for it is much better to give them a little water often, than to over-water them, eſpecially at that ſeaſon. You muſt obſerve never to ſhift thoſe plants which ſhew their fruit into other pots; for, if they are removed after the fruit appears, it will ſtop their growth, and thereby cauſe the fruit to be ſmaller, and retard its ripening; ſo that many times it will be October or November before the fruit is ripe: therefore you ſhould be very careful to keep the plants in a vigorous growing ſtate from the firſt appearance of the fruit, becauſe upon this depends the goodneſs and ſize of the fruit; for, if they receive a check after this, the fruit is generally ſmall and ill-taſted.

The method of judging when the fruit is ripe, is by the ſmell, and from obſervation; for, as the ſeveral ſorts differ from each other in the colour of their fruit, that will not be any direction when to cut them; nor ſhould they remain ſo long as to become flat and dead, as they alſo do when they are cut long before they are eaten: therefore, the ſureſt way to have this fruit in perfection, is to cut it the ſame day it is eaten; but it muſt be early in the morning, before the ſun has heated the fruit, obſerving to cut the ſtalk as long to the fruit as poſſible, and lay it in a cool, but dry, place, preſerving the ſtalk and crown to it, until it is eaten. *Miller's Gardener's Dictionary.*

ANANCITIS, in antiquity, a kind of figured ſtone, otherwiſe called ſynochitis, famous for its magical virtues in raiſing the umbræ, or ſhadows of the infernal gods.

ANAPÆST, in ancient poetry, a foot conſiſting of one long, following two ſhort ſyllables. It is the reverſe of a dactyl. See DACTYL.

ANAPHORA, in rhetoric, a repetition of the ſame word or words that concluded one ſentence at the begining of the next.

The word is Greek, and derived from αναφερω, to transfer.

ANAPLEROSIS, in a general ſenſe, implies the ſame as repletion. See REPLETION.

The word is Greek, αναπληρωσις, and derived from αναπληροω, to fill up, or recruit.

ANAPLEROSIS, among ſurgeons, ſignifies the ſupplying deficiences.

ANAPLEROTICS, in pharmacy, ſuch medicines as promote the growth of the fleſh, often called incarnatives.

ANARCHY, a confuſion introduced into a ſtate or kingdom, from its being deſtitute of a head or ruler.

The word is Greek, αναρχια, and compounded of α, priv. and αρχη, chief.

ANARTHRA, in natural hiſtory, a claſs of naked inſects, diſtinguiſhed from all others in having neither wings nor legs. The leech and all the ſpecies of worms belong to this claſs.

ANASARCA, in medicine, a ſpecies of the dropſy, wherein the ſkin appears puffed up and ſwelled, ſo that it yields to the impreſſion of the fingers like dough. See DROPSY.

The word is formed from the Greek, ανα, upon, and σαρξ, fleſh.

ANASTATICA, in botany, the name of a genus of plants, called in Engliſh the roſe of Jericho. The flower conſiſts of four roundiſh petals, diſpoſed in the form of a croſs; and its fruit is a ſhort bilocular pod, containing in each cell a ſingle roundiſh ſeed.

ANASTOMASIS, in anatomy, the opening of the mouths of the veſſels in order to diſcharge their contained fluids; as in the flux of the menſes, hæmorrhoids, bleeding at the noſe, &c.

The word is Greek, and compounded of ανα, and ϛομα, a mouth.

ANASTOMASIS alſo implies the communication of two veſſels at their extremities; as the arteries with the veins, &c.

ANATHEMA, among eccleſiaſtical writers, ſignifies whatever is ſeparated, ſet apart, or devoted; but is generally uſed to expreſs the cutting off a perſon from the privileges of ſociety, and communion with the church.

The word is Greek, and derived from ανατιθημι, to ſet apart.

There are two kinds of anathemas, the one judiciary, and the other abjuratory. The former can only be denounced by a council, pope, or biſhop; the latter makes a part of the ceremony of abjuration, the convert being obliged to anathematize the hereſy he abjures.

ANATHEMA, among the heathens, implied an offering or preſent made to ſome deity, and which was always hung up in the temple.

ANATOMICAL, ſomething belonging to anatomy.

ANATOMY, the art of diſſecting or ſeparating the ſeveral parts of animal bodies, in order to diſcover their ſtructure and uſe.

The word is Greek, ανατομη, and derived from ανατεμνω, to diſſect.

The ancients did not make any remarkable progreſs in anatomy; but the art was not neglected when the rays of learning began to ſpread their influence over Europe. Dr. Harvey publiſhed his Diſcovery of the Circulation of the blood in 1628, from which time anatomy made a ſurpriſing progreſs; and a multitude of writers on that ſcience appeared: and it would have been fortunate for anatomy, and ſtudents in this ſcience, if authors could have been ſatisfied with publiſhing their own diſcoveries, and animadverting on the errors of others; but inſtead of this many have thought that a diſcovery, ſometimes trifling enough, or a profeſſor's chair, have entitled them to write an entire ſyſtem; and by that means rendered it neceſſary to ſearch large volumes for diſcoveries, which a few pages were ſufficient to contain. Clopton Havers, an Engliſh phyſician, wrote admirably on the bones, and made ſome conſiderable diſcoveries with reſpect to the perioſteum and the marrow. He diſcovered in every joint particular glands, out of which iſſues a mucilaginous ſubſtance, whoſe nature he examined by ſeveral experiments; which, with the marrow ſupplied by the bones, conſtantly oil the joints, that both they and the muſcles might anſwer thoſe ends of motion for which nature deſigned them. This was a very uſeful diſcovery; ſince it has rendered abundance of things, before obſcure in that part of anatomy, plain and eaſy to be underſtood.

Dr. Willis, another Engliſh phyſician, was an excellent anatomiſt, particularly in what relates to the brain, nerves, ſtomach, and inteſtines. Picolhominus had, before him, obſerved that the brain, properly ſo called, and the cerebellum, conſiſt of two diſtinct ſubſtances, an outer aſh-coloured ſubſtance, through which the blood veſſels which lie under the pia mater in innumerable foldings and windings are diſſeminated; and an inner, every where united to it, of a nervous nature, that joins this ſubſtance to the medulla oblongata, which is the original of all the pairs of nerves that iſſue from the brain, and of the ſpinal marrow, that lies under the brain and cerebellum. Dr. Willis greatly improved theſe diſcoveries; he was ſo exact, that he traced this medullary ſubſtance through all its inſertions; examined the progreſs of all the nerves to every part of the body. Hence he not only demonſtrably proved the brain to be the fountain of ſenſe and motion; but alſo, by the courſes of the nerves, the manner how every part of the body conſpires with others to procure any particular motion, was clearly explained.

Pequet diſcovered the receptacle of the chyle, and ſhewed beyond contradiction, that the lacteal veſſels convey the chyle to this receptacle, and proved that it is thence carried by particular veſſels through the thorax, into the left ſubclavian vein, and ſo directly to the heart.

Alphonſus Borellus gave a mechanical account of the motion of animals, drawn from the ſtructure of the parts. As he had the advantage of Dr. Lower's diſcoveries, with reſpect to the order of the muſcular fibres of the heart, he was enabled to give a ſolution of all the appearances of the motions of the heart, and of the blood in the arteries, upon mathematical and mechanical principles. Marcellus Malpighius was deſervedly celebrated for his great ſkill and ſingular anatomical reſearches. His induſtry was not confined to the more perfect animals, but was extended to inſects, and even to vegetables, to the great improvement of natural knowledge and his own honour. He diſcovered, by means of his own microſcopes, the texture of the brain, tongue, lungs, liver and ſpleen; the mechaniſm of the reins was wholly unknown till Malpighius found it out; and by that means effectually confuted ſeveral notions, before entertained, of ſome ſecondary uſes of theſe parts, by proving that every part of the kidneys is immediately and wholly ſubſervient to that ſingle operation of freeing the blood from its ſuperfluous ſerum and ſalts. He alſo made ſome new and curious obſervations on the lymphatic veſſels and glands.

Frederic Ruyſch greatly contributed to the improvement of anatomy. This gentleman, from his infancy, devoted himſelf to phyſic, and began his firſt reſearches with the materia medica. The virtues of plants, the ſtructures of animals, the qualities of mineral bodies, chemical operations, and anatomical diſſections, were the objects that firſt ſtruck his fancy, and called for his improving hand. He was none of thoſe ſuperficial enquirers, who, either through prejudice or indolence, reſt ſatisfied before they have attained the truth: for he had ſtripped his mind of all thoſe unreaſonable attachments which are inconſiſtent with the temper of a philoſopher; and acquired ſuch an indefatigable turn, that his hardeſt labours in the purſuit of truth became his higheſt pleaſures and his only recreations.

Swammerdam, having diſcovered a method of injecting the veſſels with a certain matter, communicated his diſcovery to Ruyſch, who greatly improved it; and diſcovered a multitude of things before unknown.

Lieuwenhoek obliged the world with a great number of diſcoveries relative to anatomy, by means of his microſcopes; particularly the anaſtomaſes of the arteries and veins. Several other ingenious anatomiſts followed him, and carried the ſcience to a great degree of perfection.

Comparative ANATOMY, that which is employed in examining the bodies of brutes.

ANATOMY is uſed by ſome writers to denote the ſubject anatomized.

ANATOMY *of Plants*. See the article PLANT.

ANATRON. See NATRON.

ANAXIMANDRIANS, the followers of Anaximander, the firſt of the philoſophical atheiſts, who admitted of no other ſubſtance in nature but body.

ANCESTREL, in law, ſomething relating to, or that has been done by a perſon's anceſtors.

ANCHILOPS, in medicine, a ſmall tumour formed in the great angle of the eye, frequently degenerating into an abſceſs, or fiſtula lachrymalis.

ANCHOR, amongſt ſeamen, a ſtrong, heavy inſtrument of iron, ſunk from a ſhip to moor or retain her in a road, bay, or harbour.

An anchor is artfully calculated by the conſtruction of its parts, both to ſink into the ground when it reaches the bottom, and to bear a very great ſtrain before it can be drawn from thence by the weight of the ſhip; and, indeed, very ſeldom loſes its hold but in bad ground, (ſee the next article) ſo that the cable or rope, faſtened to it generally breaks before the anchor gives way. It is compoſed of a ſhank or ſhaft, two arms, two flukes, a ſtock, and a ring.

That the form of ſo very uſeful an inſtrument may be more clearly underſtood; let us ſuppoſe a round, maſſy beam of iron, ſtanding upright; at the lower end of which are two arms pointing north and ſouth, nearly of the ſame thickneſs with the ſhank, but tapering a little near the points, which are elevated above the horizontal plane about thirty degrees, or inclined to the ſhaft at an angle of ſixty degrees. On the upper part of each arm is a fluke, i. e. a ſtrong thick plate of iron, in form of an iſoſceles triangle, the baſe of which reaches into the middle of the arm. At the upper end of the ſhaft is fixed the ſtock, which is a long, ſquare beam of oak, in two parts, bolted together, the ends of which point eaſt and weſt. Cloſe above the ſtock is the ring to which the cable is bent or faſtened; the ring is curiouſly covered with a number of pieces of rope, equal in length to its circumference, which are firmly faſtened round it to preſerve the cable from being fretted or chafed by the iron.

Every ſhip has or ought to have three principal anchors, with a cable to each, viz. the ſheet, the beſt-bower, and ſmall-bower; there are, beſides, ſmaller anchors for tranſporting or removing a ſhip from place to place in a harbour or river, where there may not be room or wind for ſailing; ſuch as the ſtream anchor, the kedge and grappling, which laſt is however generally uſed for the boats.

To illuſtrate the foregoing deſcription, we have added a perſpective view of an anchor on plate III. *fig.* 7. where *a* is the ring to which the cable is faſtened, *b c* the beam or ſhank, *d e* the arm, or that which runs into the ground, *e f* the fluke or palm, and *g h* the ſtock.

ANCHOR-GROUND is ſuch as is neither too deep, rocky, nor too ſhallow; as in the firſt, the cable bears too nearly perpendicular, and is thereby apt to jerk the anchor from the ground; in the ſecond, the anchor is liable to hook the broken ends of rocks, and tear away the flukes, and the cable is ever in danger of being cut through by their edges; and in the third, the ſhip's bottom is apt to ſtrike in a high ſea, or at low water. An anchor is ſaid to come home when the violence of the wind or tide, acting upon the ſhip, makes her tear it up from the bed into which it had ſunk, and drag it along the ground. An anchor is ſaid to be foul when it either hooks ſome other anchor, wreck, or cable, under water; or when, by the wind abating ſuddenly, ſhe ſlackens her ſtrain and ſweeps round her anchor, taking a hitch or turn round one of the flukes with the ſlack cable, which muſt of neceſſity drag it out of the ground when the cable becomes tight: the anchor is then likewiſe ſaid to come home.

For the manner of forging anchors, ſee the article *Anchor* SMITH.

ANCHOR, in architecture, a ſort of carving reſembling an anchor. It is commonly placed as part of the enrichments of the boultins of Tuſcan, Doric, and Ionic capitals, and alſo of the boultins of the Doric, Ionic, and Corinthian cornices; anchors and eggs being carved alternately through the whole building.

ANCHOR, in heraldry, is uſed as an emblem of hope.

ANCHORAGE, a place where a ſhip may ſafely anchor.

ANCHORAGE, in law, implies a duty taken of ſhips for the uſe of the port or harbour where they come to an anchor.

ANCHORED, in heraldry, is ſaid of a croſs when its four extremities reſemble the fluke of an achor.

ANCHOVY, in natural hiſtory, the name of a ſmall fiſh, common in the Mediterranean, ſo nearly reſembling the common ſprat, that the latter has been often pickled and ſold for anchovies.

ANCHUSA, *Alkanet*, in botany, a ſpecies of burgoſs, with a rough hairy perennial plant, and unbranched procumbent ſtalks, differing chiefly from the common bugloſſes in the red colour of its roots. It grows wild about Montpelier and the eaſtern countries, and is cultivated in ſome of our gardens; but the roots produced in this climate are paler coloured than thoſe we receive from abroad.

The roots of anchuſa, when in perfection, are externally of a deep purpliſh red colour. The red cortical part, ſeparated from the whitiſh woody pith, imparts a fine deep red colour to oils, wax, and all unctuous ſubſtances, and to rectified ſpirit of wine. To water it gives only a dull browniſh hue. The ſpirituous tincture on being inſpiſſated to the conſiſtence of an extract, changes its fine red to a dark brown.

Alkanet root has little or no ſmell, and ſcarcely any taſte; nor is it regarded as a medicine. Its chief uſe is in colouring oils, plaiſters, lip ſalves, &c. which receive a fine deep red from one fortieth their weight of the root.

ANCHYLAS. See ANCHILOPS.

ANCLE, in anatomy; ſee TALUS.

ANCON, in anatomy, the gibbous eminence or flexure of the cubit.

ANCONES, in architecture, the corners or coins of walls, croſs beams, or rafters. Vitruvius calls the conſales by the ſame name.

ANCONY, in mineralogy, denotes a bloom of iron faſhioned into a flat bar, about three feet long, with a ſquare rough knot at each end.

ANCYLE, in antiquity, a kind of ſhield which, as the Romans pretended, fell from heaven in the reign of Numa Pompilius; and at the ſame time it was ſignified by a voice that Rome ſhould be miſtreſs of the world, as long as ſhe preſerved this ſacred buckler. It was therefore kept, with the utmoſt care, in the temple of Mars, under the direction of twelve prieſts, and leſt any ſhould attempt to ſteal this precious piece of armour, eleven others were made ſo like it, as not to be diſtinguiſhed from the original. Theſe bucklers were carried annually in proceſſion round the city of Rome.

ANCYLE, or ANCYLOSIS, in ſurgery, implies a diſtortion or ſtiffneſs of the joints, cauſed by a ſettlement of the humours, or a diſtention of the nerves; and therefore remedies of a mollifying and relaxing nature are required.

ANDANTI, in muſic, ſignifies that the notes are to be played diſtinctly.

ANDENA, in old writers, ſignifies the ſwarth made in mowing of hay, or as much ground as a man could ſtride over at once.

ANDREW, or *Knights of St.* ANDREW, an order of knighthood inſtituted in Scotland, generally called the order of the thiſtle. See THISTLE.

Knights of St. ANDREW is alſo an order inſtituted by Peter the Great, czar of Muſcovy, in the year 1698; the badge of which is a golden medal; on one ſide of which is repreſented St. Andrew's croſs; and on the other theſe words are engraven, *Czar Pierre monarque de tout la Ruſſie.* See plate IV. *fig.* 7.

St. ANDREW'S-DAY, a feſtival obſerved by the church on the 30th of November, in honour of the apoſtle St. Andrew.

ANDROIDES, in mechanics, a human figure, which, by certain ſprings, performs ſeveral external functions of a man.

The word is formed from the Greek, ανηρ, a man, and ειδος, reſemblance.

ANDROMACHUS'*s Treacle*, in pharmacy; ſee THERIACA.

ANDROMEDA, in aſtronomy, the name of a conſtellation of the northern hemiſphere, repreſenting a woman chained. The number of ſtars in this conſtellation, in Ptolemy's catalogue, are 23; in Tycho's 22; in Bayer's 27; and in Mr. Flamſtead's 84.

ANDROMEDA, in botany, a name given, by Linnæus, to the chamærhodendros of Tournefort. See CHAMÆRHODENDROS.

ANDROSACE, in botany, a diſtinct genus of plants, the flower of which conſiſts of one petal, broad at the top, and divided into five ſegments. Its fruit is a globular and ſingle capſule, containing a number of ſmall oval or roundiſh ſeeds fixed to a placenta.

ANECDOTE, among hiſtorians, implies ſome fact not formerly publiſhed to the world, or very little known.

The work is Greek, ανεκδοτος, and compounded of α, priv. εκδοτος, publiſhed.

ANEMUS, in ſome chemical authors, implies a wind-furnace uſed in making ſtrong fires for fluxing metals, &c.

The word is formed from the Greek, ανεμος, the wind.

ANEMOMETER, in mechanics, implies a machine for meaſuring the force or velocity of the wind.

The word is formed from the Greek, ανεμος, the wind, and μετρεω, to meaſure.

Various machines of this kind have been invented at different times, and by different authors. The following has been often experienced, and found to anſwer the intention.

An open frame of wood A B C D E F G H I (ſee plate III. *fig.* 6.) is ſupported by the ſhaft or arbor I. In the two croſs pieces H K, L M, is moved a horizontal axis Q M, by means of the four ſails *ab*, *c m*, *O f*, *g h*, expoſed to the wind in a proper manner. Upon this axis is fixed a cone of wood M N O; upon which, as the ſails move round, a weight R, or S is raiſed by a ſtring round its ſuperficies, proceeding from the ſmaller to the larger end N O. Upon this larger end or baſe of the cone, is fixed a rocket-wheel *k*, in whoſe teeth the click X falls, to prevent any retrograde motion from the depending weight.

The ſtructure of this machine ſufficiently ſhews that it may be accomodated to eſtimate the variable force of the wind; becauſe the force of the weight will continually increaſe, as the ſtring advances on the conical ſurface, by acting at a greater diſtance from the axis of motion: conſequently, if ſuch a weight be added on the ſmaller part M, as will juſt keep the machine in equilibrio in the weakeſt wind, the weight to be raiſed, as the wind becomes ſtronger, will be increaſed in proportion; and the diameter of the cone N O may be ſo large, in compariſon to that of the ſmaller end at M, that the ſtrongeſt wind ſhall but juſt raiſe the weight at the greater end.

If, for example, the diameter of the axis be to that of the baſe of the cone N O, as 1 to 28; then, if S be a weight of one pound at M on the axis, it will be equivalent to 28 pounds when raiſed to the greater end: if therefore, when the wind is weakeſt, it ſupports one pound

pound on the axis, it muſt be 28 times as ſtrong to raiſe the weight to the baſe of the cone. If therefore a line or ſcale of 28 equal parts be drawn on the ſide of the cone, the ſtrength of the wind will be indicated by that number on which the ſtring reſts.

ANEMONE, the wind-flower, in botany, a genus of plants, of which there are two ſpecies, the cultivated and the wild; and both of theſe divided into ſeveral others, eſpecially the former, many of which are kept in gardens for the beauty of their flowers.

The following method of cultivation will fully anſwer the intention, and produce very elegant anemones.

Take a quantity of freſh untried earth, (from a common or ſome other paſture-land) that is of a light ſandy loam, or hazel mould; obſerving not to take it above ten inches deep below the ſurface; and if the turf be taken with it, the better, provided it hath time to rot thoroughly before it is uſed; mix this with a third part of cow-dung, and lay it in an heap, keeping it turned over at leaſt once a month for eight or ten months, the better to mix it, and rot the dung and turf, and to let it have the advantages of a free air: in doing this work, be careful to rake out all great ſtones, and break the clods; but I would by no means approve of ſifting or ſcreening the earth, which I have found very hurtful to many ſorts of roots; for when earth is very fine, upon the firſt great rains of winter or ſpring, the ſmalleſt particles thereof join cloſely together, and form one ſolid maſs; ſo that the roots often periſh for want of ſome ſmall ſtones to keep the particles aſunder, and make way for the tender fibres, to draw nouriſhment for the ſupport of the root.

The earth ſhould be mixed twelve months before it is uſed, if poſſible; but if you are conſtrained to uſe it ſooner, you muſt turn it over the oftener, to mellow and break the clods; and obſerve to rake out all the parts of the green ſward that are not quite rotten before you uſe it, which would be prejudicial to your roots, if ſuffered to remain. The beginning of September is a proper ſeaſon to prepare the beds for planting (which, if in a wet ſoil, ſhould be raiſed with this ſort of earth ſix or eight inches above the ſurface of the ground, laying at the bottom ſome of the rakings of your heap to drain off the moiſture; but, in a dry ſoil, three inches above the ſurface will be ſufficient: this ſoil ſhould be laid at leaſt two feet and an half thick, and in the bottom there ſhould be about four or five inches of rotten neats-dung, or the rotten-dung of an old melon or cucumber bed; ſo that you muſt take out the former ſoil of the beds to make room for it.

The beſt ſeaſon for planting theſe roots is about the latter end of September; and for thoſe of a middle ſeaſon, any time in October; but obſerve to perform this work, if poſſible, at or near the time of ſome gentle ſhowers: for if you ſhould plant them when the ground is perfectly dry, and there ſhould no rain fall for three weeks or a month after, the roots will be very apt to grow mouldy upon the crown; and, if they once get this diſtemper, they ſeldom come to good after.

In the beginning of April your firſt planted roots will begin to flower, which continue for three weeks, or more, according to the heat of the weather, or management in covering them, during the heat of the day, with mats or cloths; then the ſecond-planted ſort will come to ſucceed them, and theſe will be followed by thoſe planted in the ſpring; ſo that you may have theſe beauties continued for near two months together, or ſometimes longer, if the ſeaſon be favourable.

Towards the middle or latter end of May, the leaves of your firſt blown roots will decay; at which time you muſt take them out of the ground, clearing them from decayed ſtalks, and waſhing them, to take the earth clear from the roots; then ſpread them with a mat in a dry ſhady place, till they are perfectly dried, when you may put them up in bags and hang them out of the reach of mice, or other vermin, which will deſtroy many of the roots if they come at them.

Obſerve alſo to take up the latter-planted roots as ſoon as their leaves decay; for if they are ſuffered to remain long after in the ground, and there ſhould fall ſome ſhowers of rain, they would ſoon put forth freſh fibres, and make new ſhoots, when it would be too late to remove them: at the time when you take up the roots is the proper ſeaſon for breaking or parting them, which may be done by ſeparating thoſe that you would chuſe to make all poſſible increaſe from, into as many parts as you can conveniently, provided each of them have a good eye or bud; but thoſe you intend to blow ſtrong, ſhould by no means be parted too ſmall, which greatly weakens their flowering. *Miller's Gard. Dict.*

ANEMOSCOPE, a machine that ſhews either the courſe or velocity of the wind.

The word is formed from the Greek, ανεμος, the wind, and σκοπεω, to view.

The machine which ſhews the courſe of the wind, or from what point of the compaſs it blows, conſiſts of an index moving about an upright circular plate, like the dial of a clock, on which the thirty-two points of the compaſs are drawn inſtead of the hours. The index which points to the diviſions on the dial is turned by a horizontal axis, having a trundle-head at its internal extremity. This trundle-head is moved by a cog-wheel on a perpendicular axis, on the top of which a vane is fixed that moves with the courſe of the wind, and puts the whole machine in motion. The whole contrivance is extremely ſimple, and nothing required in the conſtruction, but that the number of cogs in the wheel, and rounds in the trundle-head, be equal; becauſe it is neceſſary that, when the vane moves entirely round, the index of the dial alſo makes a complete revolution.—An anemoſcope of this kind is placed in one of the turrets of the queen's palace.

The anemoſcope, calculated for indicating the force or velocity of the wind, in the ſame with what moſt writers call an anemometer; and we have accordingly deſcribed one of thoſe machines under that article. We ſhall here add another, contrived by the late Mr. Pickering, and publiſhed in the *Philoſophical Tranſactions*, N°. 473.

This anemoſcope is a machine four feet and a quarter high, conſiſting of a broad and weighty pedeſtal, a pillar faſtened into it, and an iron axis, of about half an inch diameter, faſtened into the pillar. Upon this axis turns a wooden tube, at the top of which is placed a vane, of the ſame materials, 21 inches long, conſiſting of a quadrant, graduated and ſhod with an iron rim, notched to each degree; and a counterpoiſe of wood, as in the figure, on the other. Through the centre of the quadrant runs an iron pin, upon which are faſtened two ſmall round pieces of wood, which ſerves as moveable radii to deſcribe the degrees upon the quadrant, and as handles to a velum or ſail, whoſe pane is one foot ſquare, made of canvas, ſtretched upon four battens, and painted. On the upper batten, next to the ſhod rim of the quadrant, is a ſmall ſpring, which catches at every notch correſponding to each degree, as the wind ſhall, by preſſing againſt the ſail, raiſe it up; and prevents the falling back of the ſail, upon leſſening of the force of the wind. At the bottom of the wooden tube is an iron index, which moves round a circular piece of wood faſtened to the top of the pillar on the pedeſtal, on which are deſcribed the thirty-two points of the compaſs. The figure of this machine may be ſeen, (plate IV. *fig.* 8.) where *a* is the pedeſtal *b*; the pillar in which the iron axis is fitted: *c*, the circle of wood, on which are deſcribed the 32 points of the compaſs; *e*, the wooden tube upon its axis; *f*, the velum; *g*, the graduated quadrant; *h*, the counterpoiſe of the vane.

Fig. 9. The velum takes off: *a*, the plane of the velum; *b*, the ſpring; *c*, *c*, the wooden radii; *d*, *d*, the holes through which the pin in the center of the quadrant goes. Its uſes are the following.

1. Having a circular motion round the iron axis, and being furniſhed with a vane at top, and index at the bottom, when once you have fixed the artificial cardinal points, deſcribed on the round piece of wood on the pillar, to the ſame quarters of the heavens, it gives a faithful account of that quarter from which the wind blows.

2. By having a velum or ſail elevated by the wind along the arch of the quadrant to an height proportionable to the power of the column of wind preſſing againſt it, the relative force of the wind, and its comparative power,

at any two times of examination, may accurately be taken.

3. By having a ſpring fitted to the notches of the iron with which the quadrant is ſhod, the velum is prevented from returning back upon the fall of the wind; and the machine gives the force to the higheſt blaſt, ſince the laſt time of examination, without the trouble of watching it.

The ingenious contriver of this machine tells us, that he carefully examined what dependence may be had upon it, during the ſtorms of February, 1743-4, and found that it anſwered exceeding well; for that, in ſuch winds as the ſailors call violent ſtorms, the machine had ſix degrees to ſpare for a more violent guſt, before it comes to a horizontal poſition.

It is certainly to be depended upon in ordinary weather, the velum being hung ſo tenderly as to feel the moſt gentle breeze. There is however reaſon to fear, that the expoſing the anemoſcope to all winds for a continuance, muſt diſorder it, eſpecially irregular blaſts and ſqualls. It may not therefore be amiſs, in violent weather, for the obſerver to take the tube with its vane and velum in his hand, in order to know the force of the wind; and, when he has finiſhed his obſervations, to carry the machine into the houſe, till the violence of the ſtorm is abated, when it may be replaced in its former ſituation.

ANETHUM, *Dill*, in botany, an annual umbelliferous plant, with very finely divided leaves, and yellow flowers; producing pale yellowiſh oval ſeeds, flatted on one ſide, marked with three longitudinal ſtriæ on the other, and ſurrounded about the edges with a leafy margin. It is a native of the warmer climates, cultivated with us in gardens, flowers in July, and in September ſheds its ſeeds, by which the plant is plentifully propagated.

The ſeeds of dill have a moderately warm pungent taſte, and an aromatic ſmell, but not of the moſt agreeable kind; they are given as carminatives, to the quantity of a dram at a time, in flatulent colics, and indigeſtion from a laxity of the organs and viſcidity of the humours. The leaves are weaker and leſs grateful than the ſeeds; the roots have nothing of their flavour.

Water extracts very little of the virtues of dill ſeeds by infuſion or digeſtion for many hours. In boiling, their whole flavour exhales along with the watery vapour, and may be collected by diſtillation: the diſtilled water, drawn off to the quantity of a gallon from a pound of the ſeeds, is kept in the ſhops, and occaſionally made the baſis of carminative draughts and juleps. Along with the water ariſes a conſiderable portion of eſſential oil, in taſte moderately pungent, and ſmelling ſtrongly of the dill: this is given from one to three or four drops or more, as a carminative, aud in hiccups.

Rectified ſpirit, digeſtedon dill ſeeds, readily extracts both their ſmell and taſte: the colour of the tincture is a bright yellow. The ſpirit, gently diſtilled off from the filtered liquor, brings over very little of its flavour, leaving in the extract nearly all the active parts of the dill.

ANEURISM, in ſurgery, a tumour ariſing from the dilatation, or rupture of the coats of an artery. Aneuriſms uſually proceed from an artery being accidentally cut or pricked in bleeding, or from preternatural diſtenſion, or a corroſion of its coats, &c.

When an artery happens to be cut off by a lancet, the blood guſhes out impetuouſly by ſtarts, and is not eaſily ſtopped; an inflammation and change of colour in the part about the veſſel ſucceed, with a tumour and inability to move the arm, if the lancet were uſed there, from a collection of extravaſated blood lodged between the integuments and the interſtices of the muſcles. If the coats of the artery have been corroded, the ſymptoms are nearly the ſame, but come on more ſlowly, and prove leſs violent, without any hæmorrhage. The ſigns of a true aneuriſm, that is, when the dilatation of the coats of an artery happens, are a pulſation eaſy to be felt, and ſometimes viſible to the eye, the tumour generally appearing of the natural colour of the ſkin. This tumour varies in the magnitude, being ſometimes as large as an orange, and at others, as big as a child's head; and, when preſſed with the finger, generally gives way, but preſently reſtores itſelf upon removal thereof.

An aneuriſm happening upon ſome error in venæſection, is dangerous; but if the blood ceaſes to flow from the wounded artery, and parts itſelf between the interſtices of the muſcles, the chirurgical operation is neceſſary; or if that be delayed for a few days, the extirpation of the limb becomes indiſpenſible. It is alſo dangerous if it proceeds from a corroſion of the coats of the artery; and the more ſo when it happens in a part where the operation cannot be performed: but an aneuriſm from a diſtenſion of the canal, without any rupture, is ſeldom fatal; though rekoned when large, incurable; the chief inconveniencies being the magnitude of the tumour, and the pulſation. The diet in all theſe caſes ſhould be ſlender and balſamic, and the exerciſe gentle.

ANGARIA, in antiquity, a kind of public ſervice impoſed upon the provinces, which conſiſted in providing horſes and carriages for the conveyance of military ſtores from one place to another.

ANGARIA alſo ſignified any kind of oppreſſion or ſervice performed by compulſion.

ANGEIOGRAPHY, among anatomiſts, ſignifies a deſcription of the ſeveral veſſels of the human body; as the arteries, veins, lymphatics, nerves, &c.

The word is formed from the Greek, αγγειον, a veſſel, and γραφω, to deſcribe.

ANGEIOTOMY, in ſurgery, implies the opening a vein or artery, as in bleeding; and conſequently includes both arteriotomy and phlebotomy.

The word is formed from the Greek, αγγειον, a veſſel, and τεμνω, to cut.

ANGEL, a name given to thoſe ſpiritual intelligent beings who are ſuppoſed to execute the will of the Divine Being in the government of the world.

The word is Greek, αγγελος, and derived from αγγελλω, to carry a meſſage, or execute an order.

All religions have admitted of the exiſtence of angels. The Greeks and Latins acknowledged them under the names of genii and demons; and in the alcoran we find frequent mention of them; the profeſſors of the Mahometan religion aſſigning them various orders and degrees, as well as different employments, both in heaven and earth.

Nothing is more frequent in ſcripture than the miſſions and apparitions of good and bad angels: God ſends them to declare his will, to correct, teach, reprove, and comfort: God gave the law to Moſes, and appeared to the old patriarchs by the mediation of angels, who repreſented him and ſpoke in his name. The exiſtence of angels is ſuppoſed in all religions.

Though the Jews in general believed the exiſtence of angels, there was a ſect among them (the Sadducees) who denied the exiſtence of all ſpirits whatever, God only excepted: and yet the Samaritans and Caraites, whom the Jews repreſented as Sadducees, acknowledged ſuch beings. Before the Babyloniſh captivity, the Hebrews ſeem not to have known the name of an angel: the Talmudiſts ſay they brought them from Babylon: it is true we find many of them called by their names in the book of Enoch; but this we know is ſpurious, and was written after the captivity we are ſpeaking of. Tobit, who is thought to have lived at Nineveh, ſome time before the captivity, is the firſt who was called an angel by his proper name: he mentions Raphael, who conducted Tobias into Media; and Daniel, who lived at Babylon ſome time after Tobit, has taught us the names Michael and Gabriel. In the New Teſtament we find only the two latter angel mentioned by name. It has been queſtioned, whether the ancient Hebrews paid divine homage to angels or not. The form of benediction which Jacob uſed in bleſſing the ſons of Joſeph, (the angel which redeemed me from all evil bleſs the lads) may ſeem to imply that they did. The rabbins, in gloſſing upon the text, obſerve, that the prayers of their anceſtors were not directly addreſſed to angels, but it was really God they invoked, when they prayed to them; they only go to them as to the king by his miniſters, and as one that preſents his petition to the firſt officer of the crown; yet ſtill looks to the king as the ſource and ſpring of his happineſs and favour that he has received. But this expoſition is refuted by others, who remark that Jacob, after he had directly applied himſelf to God, and begged of him both temporal and eternal bleſſings on his two grand-ſons, then addreſſed himſelf to the angel, to obtain of him, that he would keep them from all evil; from whence they conclude, that Jacob addreſſed his prayers directly to the angel to whom he aſcribed the power of preſerving from evil, whilſt he left to God the privilege of beſtowing all that was good; and if the prayer of the patriarch was implicitly addreſſed to God, as the fountain of goodneſs, yet he certainly prayed explicitly to the angel. But, notwithſtanding this diſpute, the beſt Chriſtian expoſitors deny that this invocation of Jacob implies any thing like a prayer to the angel. Some indeed conceive, that the angel in this place is the ſecond perſon in the trinity; an opinion refuted by others, who more juſtly ſay, that Jacob intended no more than a deſire that his children might enjoy the angelical protection, by the ſpecial favour of God to them; for it is ſuch an expreſſion as that of David to a contrary purpoſe, "Let the angel of the Lord perſecute them," where no one will ſay he prays to an angel, though his words are exactly like thoſe of Jacob.

There are divers opinions concerning the time when angels were created. Some think they were created at the ſame time as the Heavens; and that Moſes included them under this name, ſaying, "In the beginning God created the Heavens." Others have conjectured, that he inclined to repreſent them under the name of light, which God created the firſt day; of this opinion is St. Cyril. Others again have aſſerted, that they were created before the ſenſible world; which opinion Job ſeems to favour, when he ſays, "Where waſt thou when I laid the foundation of the earth;—and all the ſons of God ſhouted for joy?" The Hebrews think they were created on the ſecond day of the world; and that God conſulted with the angels when he ſaid, "Let us make man in our own image." Others are of opinion, that angels were created on the fifth day. Origen, and other Greek and Latin fathers, think they exiſted before the world; and Dr. Hyde thinks a very long time before the world. See *Baſnage's Hiſt. des Juiffs*, lib. 4. cap. 9. The philoſophers of the Peripatetic ſect believed they were coæval with God; and, conſequently, that they exiſted from all eternity. The Greek fathers of the Chriſtian church were generally inclined to believe they were created before the world. Some few, indeed, were of different opinions, among whom is Epiphanius.

Though it is an univerſal opinion that angels are of a ſpiritual, incorporeal nature, yet many of the old fathers, miſled by a paſſion in Geneſis, where it is ſaid, "That the ſons of God (or the angels) ſaw the daughters of men, that they were fair, and they took them wives of all which they choſe," imagined them to be corporeal, and capable of ſenſible pleaſures. Other fathers indeed, and thoſe in great number, have aſſerted angels to be purely ſpiritual; and this at preſent is the common opinion of the ſchools.

There have been a great many diſputes and varieties of fancy concerning the number, order, nature, and power of angels; moſt of which are not to be reſolved by ſcripture or tradition. The author of the books *De Hierarchia cæleſti*, who wrote about the beginning of the ſixth century, is the firſt who ventures to range the angels into three hierarchies and nine orders. The Jews likewiſe diſtinguiſhed them into ſeveral orders, and ſet, as it were, a general at the head of them; they called him Metatron, the ſame with the Chriſtian St. Michael.

As to the office or employment of angels, ſome are ſaid to preſide over empires, nations, provinces, cities, and particular perſons. Theſe latter are ſtiled guardian angels. Thus St. Michael is acknowledged to be the protector of the people of Iſrael; and the angel Gabriel ſpeaks of the angel who was protector of Perſia, according to the generality of interpreters, when he ſays that the prince of the kingdom of Perſia withſtood him one and twenty days. St. John wrote his Revelations to the angels of the ſeven chriſtian churches in Aſia Minor, whereby he does not mean only the biſhops of thoſe churches, but, in the judgment of many of the fathers, the angels alſo who were appointed for their protection. The learned Dr. Prideaux obſerves, that the miniſter of the ſynagogue, who officiated in offering up the public prayers, being the mouth of the congregation, delegated by them as their repreſentative, meſſenger, or angel, to ſpeak to God in prayer for them, was therefore, in the Hebrew language, called the angel of the church; and from thence the biſhops of the ſeven churches of Aſia are, by a name borrowed from the ſynagogue, called the angels of thoſe churches. As to guardian angels, they are very clearly deſcribed in the Old Teſtament. Jacob ſpeaks of the angel who had been his guide in all his journies, and had delivered him out of all his dangers. The Pſalmiſt, in ſeveral places, mentions angels as the protectors of the righteous. In the New Teſtament we hear of St. Peter's angel who ſet him at liberty; and Jeſus Chriſt enjoins us not to deſpiſe little ones, becauſe their angels continually behold the face of God. The Jews, and the very heathens, believed that particular angels were commiſſioned to attend us, and had the care of our conduct. Heſiod, the moſt ancient, or at leaſt one of the moſt ancient Greek authors, ſays, that there are good angels upon earth, ſent by Jupiter for the protection of mankind, and to obſerve the good or evil which they practiſe. Plato ſays, that every one of us has two demons, or two genius's, one inclining us to evil, the other directing us to good; though Apuleius ſays, that Plato aſſigned but one demon to every man. The ancient Chriſtians, as Origen and St. Auguſtine, aſcribe to angels the office of preſenting our prayers to God; and the Chriſtians, in general, agree with the Platoniſts, that God makes uſe of the miniſtry of angels, to carry his orders, to work miracles, and to foretel future events.

Angel, in commerce, the name of a gold coin formerly current in England. It had its name from the figure of an angel repreſented upon it, weighed four pennyweights, and was twenty-three and a half carats fine. It had different values in different reigns; but is at preſent only an imaginary ſum, or money of account, implying ten ſhillings.

ANGELICA, in botany, a large umbelliferous plant, with hollow-jointed ſtalks, and indented oval, pointed leaves, ſet in pairs along the middle rib, and having an odd one at the end, containing a milky juice, which on drying contracts a yellowiſh colour; the ribs of the leaves are channelled on the upper ſide, and joined to the ſtalks by large membraneous baſes or ſheaths. The ſeeds are of a pale whitiſh colour, ſomewhat oval, flat on one ſide, and convex, with three longitudinal ridges on the other, ſurrounded about the edges with a leafy margin. The roots are long and thick, of a dark brown colour on the ſurface, but the internal white and juicy; and, when dry, of a ſpongy texture.

There are two ſpecies of angelica, the wild and the garden, diſtinguiſhed by the epithets *ſylveſtris* and *ſativa.* The former grows wild, in moiſt grounds, in ſeveral parts of England; is pirennial, and flowers in July: the latter is cultivated in gardens. They are ſimiliar in quality; but the latter ſuppoſed to be the ſtronger.

The garden angelica is naturally a biennial plant; but if the ſtalks are cut down before they run to flower, the roots will ſend forth new heads, and may, by this means, be continued for many years. The roots are in their greateſt perfection in the ſecond ſpring: they ſhould be thoroughly dried, kept in a dry place, and frequently aired, otherwiſe they will grow mouldy, and be eaten by worms.

The roots of angelica are one of the principal aromatics of European growth, though not much regarded in the preſent practice. They have a fragrant agreeable ſmell, and a bitteriſh pungent, mixed with a pleaſant ſweetiſh taſte. On wounding the freſh roots early in the ſpring, it yields from the inner part of the bark, an unctuous and odorous juice of a yellowiſh colour; and which, being gently exſiccated, retains its fragrance, and proves an elegant aromatic gummy-reſin. On cutting the freſh root longitudinally, the yellowiſh matter, in which the virtue and flavour of the angelica reſides, appears concreted into little veins. In this ſtate it readily and totally diſſolves by rectified ſpirit of wine, and tinges the menſtruum of a bright golden colour. On diſtilling off the ſpirit from this ſolution, very little of the flavour of the angelica riſes with it, nearly all the active matter of the root remaining concentrated in the extract. Water alſo gains from this root a pretty deep yellow colour, but extracts little of its taſte or ſmell. In diſtillation with water, there ariſes a ſmall portion of eſſential oil, of a highly pungent taſte, and ſmelling ſtrongly of the angelica: the remaining decoction, thus diveſted of the aromatic matter of the root, is nauſeouſly ſweetiſh and ſubacrid.

The other parts of the plant have the ſame taſte and flavour with the roots; but their active principles are far more periſhable. The ſeeds, which come neareſt to the roots, can ſcarcely be kept till the ſpring after they have been gathered, without loſing their vegetative power, as well as diminiſhing their medicinal virtues; and, with regard to the leaves, they loſe the greater part of their virtues on being barely dried: for ſome purpoſes, however, they are well adapted; the freſh leaves, as well as the ſeeds, being diſtilled with water, give over to the liquor, the whole of their aromatic matter, which in this form proves ſufficiently durable. The virtues of the ſeeds, like that of the roots, is very imperfectly extracted by water, and completely by ſpirit; and though it riſes totally by diſtillation with water, is left by the ſpirit almoſt entire in the inſpiſſated extract. The ſpirituous tincture is of a bright ſtraw colour; the watery infuſion of a dark brown.

The ſtalks, candied with ſugar, make a very agreeable ſweetmeat.

Angelica, in antiquity, the name of a celebrated dance performed at the pagan feaſts of Greece; and ſo called from the dancers being dreſſed in the habit of meſſengers.

ANGELICS, *Angelici*, in eccleſiaſtical hiſtory, an ancient ſect of heretics, ſuppoſed to have obtained this appellation from their exceſſive veneration for angels.

Angelics is alſo the name of a congregation of nuns, founded at Milan in 1534, by Louiſa Torelli, counteſs of Guaſtalla. They obſerve the rule of St. Auguſtine.

Angelics is likewiſe the name of an order of knights inſtituted in 1191, by Angelus Flavius Comnenus, emperor of Conſtantinople.

Some will have this order, which ſtill ſubſiſts in Italy, to have been much more ancient, and that Conſtantine the Great was its founder.

ANGELITES, in eccleſiaſtical hiſtory, a ſect of Chriſtian heretics, in the reign of the emperor Anaſtaſius, and the pontificate of Symmachus, about the year 494; ſo called from Angelium, a place in the city of Alexandria, where they held their firſt meetings. They were called likewiſe Severites, from one Severus, who was the head of their ſect; as alſo Theodoſians, from one among them, named Theodoſius, whom they made pope at Alexandria.

They held, that the perſons of the Trinity are not the ſame; that none of them exiſts of himſelf, and of his own nature, but that there is a common god, or deity, exiſting in them all; and that each is God, by a participation of this deity.

ANGELOT, the name of a gold coin ſtruck at Paris, while ſubject to the Engliſh; and ſo called from the figure of an angel, ſupporting the arms of England and France.

ANGER, a violent paſſion of the mind, conſiſting in a propenſity to take vengeance on the author of ſome real or ſuppoſed injury done the offended party.

ANGERONA, in mythology, the name of a pagan deity whom the Romans prayed to for the cure of a diſtemper, called the quinſy, in Latin, *angina*. Pliny calls her the goddeſs of ſilence and calmneſs of mind, who baniſhes all uneaſineſs and melancholy. She is repreſented with her mouth covered, to denote patience and refraining from complaints. Her ſtatue was ſet up, and ſacrificed to, in the temple of the goddeſs Volupia, to ſhew that a patient enduring of affliction leads to pleaſure.

ANGERONALIA, feaſts inſtituted at Rome in honour of the goddeſs Angerona. They were celebrated on the 21ſt of December.

ANGINA, in phyſic, a violent inflammation of the throat, generally called quinzy. See the article Quinzy.

Angina *Lini*, in botany, a name by which ſome call the dodder growing on flax, from its choaking that plant.

ANGIOSPERMA, in the Linnæan ſyſtem of botany, implies thoſe plants of the didynamia claſs, which have their ſeeds incloſed in a capſule or ſeed veſſel.

ANGLE, *Angulus*, in geometry, is the mutual inclination of two lines, which meet and form an angle in their point of interſection. Such is the angle B A C, (plate X. *fig.* 3.) formed by the right lines A B, A C, meeting in the point A. The lines A B and A C are called the legs of the angle, and point of interſection, the vertex.

Angles are ſometimes denoted by a ſingle letter affixed to the vertex, or angular point, as A, and ſometimes by three letters, whereof the middle letter ſhews the angular point. Thus the angle formed by the right lines A B, A C, meeting in the point A, is called the angle B A C, or C A B.

The Meaſure of an Angle is the arch of a circle deſcribed on the angular point, intercepted between the two lines which form the angle. Thus the meaſure of the angle B A C is the arch E F, intercepted between the two legs A B, A C; and as many degrees as are contained in that arch, ſo many degrees the angle B A C is ſaid to conſiſt of.

Hence it will be eaſy to meaſure the quantity of any angle geometrically; for if you take the diſtance of the arch E F, intercepted between the lines A B, A C, and apply it to a line of chords, whoſe radius is A E, you will have the number of degrees contained in the angle B A C; or if you apply the center of a protractor to the angular point A, in ſuch a manner that the leg A B lies directly under the limb of the protractor, the degree on the arch cut by the other leg A C will give the quantity of the angle required.

Angles are either *right*, *acute*, or *obtuſe*.

A right Angle is that whoſe legs are perpendicular to each other, as A B C (plate X. *fig.* 6.) the arch intercepted between them being exactly 90°.

An Acute Angle is that which is leſs than a right angle or 90°. as the angle D B C.

An Obtuſe Angle is that which is greater than a right angle, as E B C.

Adjacent Angles are ſuch as have the ſame vertex, and one of the legs continued beyond the angular point. Thus the angles C E B and C E A (*fig.* 4.) are adjacent angles. The ſum of theſe adjacent angles is always equal to two right angles; (13 Euclid. 1.) and therefore, if one of them be acute, the other will be obtuſe, and the contrary. Whence if either of them be given, the other is alſo given, it being the ſupplement of the former.

Vertical Angles are thoſe formed by two right lines interſecting each other. Thus the right lines A B, C D, (*fig.* 4.) by their interſection in E, form the vertical angles A E C, D E B, and A E D, C E B.

Alternate Angles are thoſe acute or obtuſe angles formed by a right line cutting two parallel right lines. Thus if A B and C D (*fig.* 5.) are parallel, and G H cuts them in I and K, the angles A I K, D K I, and B I K, I K C, are alternate angles.

The alternate angles are always equal to each other. (18 *Eucl.* 1.)

Angle *at the Center of a Circle*, is an angle in a circle, whoſe vertex is in the center of that circle.

Angle *at the Periphery*, or *in a Segment*, is an angle whoſe vertex is in the periphery, and its legs two chords of the circle. Thus A B, B C, are two chords of the circle A B C D, (*fig.* 8.) making an angle B at the periphery, which is called an angle in a ſegment.

This angle is always equal to half the angle at the center, ſtanding upon the ſame arch (6 Euclid. 3.) Alſo all angles in a ſegment, ſtanding upon the ſame arch, are equal to one another. Thus the angles A B C, A G C, A F C, are equal, and are each equal to half the angle A E C at the center.

If the right line A B (*fig.* 9.) touch the circle in C, and the chord C D be drawn, then will the angle A C D be equal to any angle C E D, made in the ſegment D E C. (Euclid. 32. 3.)

When the arch is a ſemicircle, the angle will be a right angle. Thus if the arch A B C (*fig.* 11.) be a ſemicircle, the angle A B C will be a right angle. When it is greater than a ſemicircle, as *fig.* 12. the angle will be acute; but when leſs, as *fig.* 10. it will be obtuſe. (31 Euclid. 3.)

Spherical ANGLE is an angle formed by two great circles of the ſphere.

Thus, let A C D E B (*fig.* 15.) repreſent a ſphere, upon whoſe ſurface let two arches of great circles A B, C E, be drawn, interſecting each other in the point D; then will A D C, D C A, B D E, or D B E, be a ſpherical angle.

The meaſure of a ſpherical angle, as A D C, is the arch of a great circle A C, deſcribed from the vertex A, as its pole, and intercepted between the legs A D, C D; or it is the diſtance of the poles of the two circles A B, C E: becauſe the meaſure of a ſpherical angle is the ſame as the inclination of the planes of the great circles that form it, and the meaſure of the quantity of the inclination is the arch A C, D being the pole of the great circle A C B E A.

Mixed Line ANGLE is that comprehended between a right line and a curve line, as the angle A B C (*fig.* 14.).

ANGLE *of Communication*, in aſtonomy, is the diſtance between the true place of the ſun ſeen from the earth, and the place of a planet reduced to the ecliptic. Thus let T F (*fig.* 13.) be the orbit of the earth T, A P G that of the planet P, S the ſun, and B the planet's place reduced to the ecliptic; then will the angle T S B be the angle of communication.

ANGLE *of Contact* is that formed by a tangent, and its curve at the point of contact. Thus, if the right line A B (plate XII. *fig.* 1.) touch the circle H A K E, in the point A, the angle B A K is an angle of contact. Euclid demonſtrates that the right line A B, ſtanding perpendicular on the radius C A, touches the circle only in one point; nor can there be any other right line drawn between the tangent and the circle. Hence the angle of contact is leſs than any rectilinear one, and the angle of the ſemicircle between the radius C A, and the arch A K, is greater than any rectilinear acute angle.

This paradox of Euclid has exerciſed the wits of the mathematicians: it was the ſubject of a long controverſy between Peletarius and Clavius, the firſt of whom maintained the angle of contact heterogeneous to a rectilinear one, as a line is heterogeneous to a ſurface; the latter maintained the contrary. Dr. Wallis has a formal treatiſe on the angle of contact, and of the ſemircircle, where, with other great mathematicians, he approves of the opinion of Peletarius. Sir Iſaac Newton ſhews that, if the curve H A E be a cubic parabola, the angle of contact, where the ordinate D F is as the cube root of the abſciſſa, the angle B A F contained under the tangent A B in its vertex and the curve, is infinitely greater than the circular angle of contact contained by the ſaid tangent and the arch of the circle; and that, if other parabolas of higher kinds be deſcribed to the ſame axis and vertex, whoſe abſciſſas A D are as the ordinates DF^4, DF^5, DF^6, &c. you will have a ſeries of angles of contact going on infinitely, of which any one is infinitely greater than that next before it. See CURVATURE.

ANGLE *of Incidence* is that which the line of direction of a ray of light, &c. makes at the point where it firſt touches the body it ſtrikes againſt, with a line erected perpendicular to the ſurface of that body. Thus, if a ray of light, &c. move in the direction A B, (plate XII. *fig.* 2.) till it touch the ſurface *a b c d*, in the point B, then will the angle intercepted between A B, the line of direction, and the perpendicular B F, be the angle of incidence.

ANGLE *of Reflection* is the angle intercepted between the line of direction of a body rebounding, after it has ſtruck againſt another body, and a perpendicular erected at the point of contact. Thus, if a body moving in the direction A B (plate XII. *fig.* 2) ſtrike the ſurface *a b c d* in the point B, and is reflected in the direction B C, the angle contained between that line and the perpendicular B F, is called the angle of reflection.

The angle of incidence is always equal to the angle of reflection; and, upon this equality, the whole ſcience of catoptrics is founded.

ANGLE *of Emergence* is that which any body, as a ray of light, &c. projected from one fluid or medium into another, makes with its quitting the latter medium with a perpendicular to its ſurface. Thus, let A B and C D (plate XII. *fig.* 3.) be parallel planes terminating water or glaſs, and ſuppoſing a body, projected in the direction F E, entering this medium at E, and going out of it at G, in the direction G H or G M; let G K be perpendicular to A B, C D, then the angle K G H, or K G M, is an angle of emergence. The ſine of the angle of emergence, when the projected body paſſes quite through the medium, is to that of incidence in a conſtant ratio: but when the projected body flies back or out of the medium, the ſame way it entered it, without paſſing through, then the angle of incidence will always be equal to the angle of emergence. In order to demonſtrate theſe uſeful and fundamental propoſitions in a conciſe manner, we will ſuppoſe it admitted that nature, in all its operations, takes the ſhorteſt ways. Now, as light cannot move in different mediums with the ſame velocity, let the ratio of the velocity of light, during its motion from A to B, (plate XII. *fig.* 4.) where it begins to be refracted to its velocity, while it is refracted in its motion from B to C, be expreſſed by $\frac{m}{n}$; then the times of the deſcriptions of the lines A B, B C, will be as $n \times AB$ to $n \times BC$. Let fall the perpendiculars A Q, C P, and make $AQ=a$, $CP=b$, $PQ=c$, $PB=x$, then will $BQ=c-x$, and conſequently $BC=\sqrt{b^2+x^2}$, and $AB=\sqrt{aa+cc-2cx+x^2}$, whence the time in which A B + B C is moved through, is $= m \times \sqrt{b^2+x^2} + n \times \sqrt{a^2+c^2-2cx+x^2}$, which muſt be a minimum; and ſo the fluxion thereof, viz. $\frac{m x \dot{x}}{\sqrt{b^2+x^2}} + \frac{n x \dot{x}}{\sqrt{a^2+c^2-2cx+x^2}} = 0$. Whence $\frac{m x}{\sqrt{b^2+x^2}} = \frac{n \times \overline{c-x}}{\sqrt{a^2+c^2-2cx+x^2}}$, that is, $m \times \frac{PB}{BC} = n \times \frac{BQ}{AB}$, make $BC=AB$; then will $m \times PB = n \times BQ$; and conſequently $m:n::BQ:PB$.

Whence if A B or B C be taken for the radius, B Q will be the ſine of the angle A, and P B the ſine of the angle C; that is, ſince A Q and P C are parallel to D E, P B is the ſine of the angle C B E, and B Q the ſine of A B D; viz. P B is the ſine of the refracted angle, and B Q the ſine of the angle of incidence. Whence the ſine of the angle of incidence is to the ſine of the refracted angle in a conſtant ratio, viz. that of the velocity of light before refraction to the velocity during its refraction.

ANGLE *of Refraction*, in dioptrics, is the angle which a ray of light refracted, makes with a ray of incidence, continued beyond the refracting ſurface. Thus, let D E (plate XII. *fig.* 5.) be the refracting ſurface. M N a ray of incidence, and N E the refracted ray; alſo let N H be the continuation of the ray of incidence, then is F N H the angle of refraction.

Refracted ANGLE is the angle which a refracted ray forms with a perpendicular to the refracting ſurface. Thus, let G N be the perpendicular to the refracting ſurface D E, then is G N F the refracted angle. There are ſeveral methods for obſerving the quantity or law of refraction; but the following, which is very eaſy to be underſtood, will be ſufficient; and, as the refraction from air to glaſs is chiefly wanted in dioptrics, we have choſen it for an example.—Let F G E B C (plate XII. *fig.* 6.) repreſent a well poliſhed glaſs cube, ſtanding upon a plane board N I P O, at the end of which there is another N A B I, fixed at right angles, having the ſame height C H with the ſide of the cube, and let their common breadth I N be greater than the ſide I H of the cube, and the length O N be much longer than either; then let theſe boards, with the cube fixed on them, be turned to the ſun at different altitudes above the horizon, and note the end of the ſhadow of the ſide A B, both within the cube at K, and without it at L; then, ſince C K is the refracted ray, and C L the unrefracted one, H C K will be the refracted angle, and H C L the angle of incidence: ſo that if C L be ſuppoſed the radius, H L will be the ſine of the angle of incidence, and H K that of the refracted angle; ſo that if H K and H L be carefully meaſured by an exact ſcale of equal parts, you will have in numbers the ratio of the ſines of the angle of incidence to that of the refracted angle. If, inſtead of a cube of glaſs, you uſe a little veſſel of water, or other liquors, you may obſerve the law of refraction in theſe mediums.

Optic ANGLE, or ANGLE *of Viſion*, is the angle formed at the bottom of the eye by two rays iſſuing from the extreme points of an object. Thus the angle A B C, (plate XII. *fig.* 7.) formed by the rays A B, C B, iſſuing from the extreme points A, C, of an object, is the optic angle.

ANGLE *of the Sun's Poſition* is an angle formed by the meridian, and an azimuth, or other great circle, drawn through the center of the ſun.

ANGLE *of Longitude* is an angle formed at the pole of the ecliptic between the meridian, and a circle of longitude drawn through the center of the object.

ANGLE *of the Courſe*, in navigation; ſee COURSE and RHUMB.

ANGLE *at the Center*, in fortification, is that formed at the center of the figure, by lines drawn thence to the points of the baſtions, Thus X A Q (plate XII. *fig.* 8.) is an angle at the center.

ANGLE *of a Baſtion* is the angle I Q O, which the two faces I Q and O Q form at the point of the baſtion.

ANGLE *of the Tenaille* is the angle I X M I, formed before the curtain by the two lines of defence X P and Q N.

Diminiſhed ANGLE is the angle I Q X (*fig.* 8.) formed by the line I Q, the face of the baſtion, and X Q the exterior ſide of the polygon.

Re-entering ANGLE is any angle in a fortreſs, whoſe point turns inwards, or towards the place; that is, whoſe legs open towards the field.

Salient ANGLE is that which points outwards, or whoſe legs open towards the place.

ANGLE *of the Polygon* is the angle D X Q, (*fig.* 8.) or X Q K, formed by two ſides of the polygon.

ANGLE *of the Complement of the Line of Defence* is the angle formed by the interſection of the two complements with each other.

ANGLE *of the Mote* is that formed before the curtain where it is interſected.

ANGLES *of a Battalion*, in military affairs, are the laſt men where the ranks and files terminate.

ANGLING, the art of fiſhing with a rod, to which are fitted a line, hook, and bait.

The following rules are neceſſary to be obſerved in angling. 1. To place yourſelf ſo that your ſhadow do not at any time fall upon the water, eſpecially if it be ſhallow. 2. To angle in a pond near the ford where cattle go to drink, and in rivers, in ſuch places as the fiſh you angle for uſually frequent; as, for breams in the deepeſt water; for eels under banks; for chub in deep ſhaded holes; for perch and roach in ſcowrs; for trouts in quick ſtreams.

The beſt times for angling are from April to October; for in cold ſtormy weather, or bleak eaſterly winds, the fiſh will not bite. The time of the day, in warm months, is in the morning, about nine o'clock, and in the afternoon between three and four. In order to attract fiſh to the place intended for angling, it will be proper once in four or five days to throw in ſome corn boiled ſoft, garbage, worms chopped to pieces, or grains ſteeped in blood and dried; and, if you fiſh in a ſtream, it will be beſt to throw in the grains above the hook.

The beſt method of angling with a fly is down the ſtream; and, in order to make the fiſh bite freely, be ſure to uſe ſuch baits as you know they are naturally inclined to, and in ſuch a manner as they are accuſtomed to receive them.

The ſeveral methods for angling for ſalmon, trout, carp, tench, perch, pike, dace, gudgeons, roach, flounders, &c. will be found under the articles *Salmon* FISHING, *Trout* FISHING, &c.

ANGLO-SAXON, a name given to the language ſpoken by the Engliſh Saxons, in order to diſtinguiſh it from the true Saxon, and alſo from the modern Engliſh.

ANGONÆUS, in anatomy, a name given to a muſcle of the arm, inſerted into the ancon, or extremity of the elbow.

ANGUILLA, in natural hiſtory, the name by which the writers in that ſcience call the eel. See EEL.

ANGUINEAL *Hyperbola*, a kind of ſerpentizing hyperbola, cutting its aſymptote with contrary flexions.

Sir Iſaac Newton, in his Treatiſe of Curves, has given this name to the 33, 34, 35, and 36 ſpecies of the ſecond order, and which he has expreſſed by this equation, $xyy.\, ey = -\, ax^3.\, bx^2.\, ex.\, d.$

ANGULAR, ſomething relating to, or that hath, angles.

ANGULAR *Motion*, in aſtronomy, is the increaſing or decreaſing angle, formed by two lines drawn from a central body to the apparent places of the two planets in motion.

ANHELATIO, or ANHELITUS, among phyſicians, a ſhortneſs of breath, or a difficult and ſmall, but quick, reſpiration, which happens to ſound perſons, eſpecially to valetudinarians, after violent exerciſe.

The word is Latin, and derived from *anhelo*, to pant, or breathe with difficulty.

ANHIMA, in natural hiſtory, the name of a bird, common in Brazil, reſembling a crane in ſome particulars; but differing from that and all other birds by a ſlender horn of a bony ſubſtance, inſerted a little above the origin of its beak: its wings too have each a horn of this kind growing out of the fore-part of the bone. It is larger than a ſwan, and mottled with black, grey, and white; in ſome parts are ſmall ſpots of yellow. See plate XII. *fig.* 9.

ANHINGA, in natural hiſtory, an extremely beautiful water fowl, found in the Brazils, about the ſize of our common duck. Its beak is about an inch and a half in length, and has a row of hooked prickles, both above and below; its neck is long and ſlender, and, together with its head, of a yellowiſh colour; the upper part of the back is brown, ſpotted with yellow; and the breaſt, belly, and thighs, are of a ſilvery white.

ANIL, in botany, the name by which ſome writers call the plant that produces indigo. See the article INDIGO.

ANIMA, the ſoul, or principle of life in animals. See the article SOUL.

ANIMA *Mundi*, the ſoul of the univerſe, is, according to ſome, a certain, pure, æthereal ſubſtance, which, being diffuſed through the whole maſs of matter, informs, actuates, and unites the various parts of it into one great, perfect, organical body. Others define it to be an ignific virtue, infuſed into the chaos, and diſſeminated through the whole frame for its conſervation, nutrition, and vivification.

The moderns reject this notion of an anima mundi, as the notion is abſolutely repugnant to experience.

ANIMADVERSION, a term ſometimes uſed to ſignify correction; ſometimes remarks, and ſometimes ſerious conſideration.

The word is Latin, *animadverſio*, and compounded of *animus*, the mind, and *verto*, to turn.

ANIMAL, in natural hiſtory, an organized body, endowed with life and ſpontaneous motion.

Boerhaave defines an animal, reſpecting only the body, not the ſoul, to be an organical body, conſiſting of veſſels and juices; and taking in the matter of its nutriment by a part called a mouth; whence it is conveyed in the inteſtines, into which it has roots implanted, whereby it draws in its nouriſhment after the manner of plants.

According to this definition, an animal is diſtinguiſhed from a foſſil, in that it is an organical body; and from a vegetable by this, that it has its roots within itſelf, and a plant without itſelf.

In effect, the inteſtines of an animal are, in reality, no more than its earth, or the body it adheres to; into which it ſends forth its roots, that is, the lacteal veſſels, which thence draw the matter of its life and increaſe.

The general characteriſtic then of an animal is, to be free and at large with reſpect to the ſubject it derives its nouriſhment from; for every thing is taken in at the mouth, and the mouth does not adhere to any thing: whereas all plants are connected in ſome manner or other to the body, which furniſhes them with food.

Hence it follows, that a fœtus, while it remains in the mother's womb, is a real plant, as being connected by the funiculus umbilicalis to the placenta, and by the placenta to the uterus, from whence it receives its nouriſhment.

If it did not derive its food by the ſaid funiculus, but by its mouth, it were an animal, and if it drew it by both, a neophite, or plant-animal.

Some have defined animals from their local motion, as being capable of ſhifting from place to place, and plants from ſticking faſt to the ſame ſubject: but on this principle, oyſters, muſcles, cockles, &c. are excluded from the claſs of animals, inaſmuch as they adhere or grow to rocks, &c. yet it is certain that thoſe creatures are real animals, as they have mouths and ſtomachs to take in their food; and lacteals, meſentery, and veins to receive it.

According to Dr. Tyſon, the criterion of an animal is the ductus alimentalis, i. e. a gullet, ſtomach, and inteſtines; all which make but one continued canal.

All animals, according to the moſt probable and received opinion, are produced originally from eggs, in which they are contained, till the ſeed of the male penetrate their covering and ſtretch them, ſo as they become ready for hatching.

When the animal breaks looſe from its ſhell in its perfect form, we ſay the dam of it is viviparous; when the young is excluded with hard covering round it, which we call the ſhell, we ſay the dam is oviparous. The ſhell of the egg in the oviparous kind is hard and convexed, the better to reſiſt the preſſure and the injuries of the air, to which it muſt lye expoſed for ſome time.

All animals that are found with feet, fins, or wings, and have the free power of tranſporting themſelves from one place to another, are divided into two ſexes under each ſpecies, that they may confer their joint offices in rearing their young. On the other hand, thoſe animals which are confined all their life to one ſpot are hermaphroditical, or have both ſexes conjoined in one body, and procreate their ſpecies without the concurrence of a mate. Of this ſort are limpets, ſea-ears, and ſeveral other kinds of ſhell-fiſh.

The philoſophers comprehend man under the ſpecies of animals, and define him a reaſonable animal: though among naturaliſts, &c. animals are uſually reſtrained to irrationals.

Animals may be conſidered either as aerial, terreſtrial, aquatic, or amphibious. We call thoſe aerial which have wings, with which they can ſupport themſelves in the air.

Terreſtrial are thoſe whoſe only place of reſt is upon earth. Aquatic are thoſe whoſe conſtant abode is upon the water.

Thoſe are called amphibious which live freely in the air upon the earth, and yet are obſerved to live long on the water, as if they were natural inhabitants of that element.

Aerial animals may be ſubdivided into birds and flies. Fiſhes, which are the chief part of aquatic animals, may be divided into ſhell-fiſhes, ſcaly fiſhes, and thoſe that have neither apparent ſcales nor ſhells.

And terreſtrial animals may be divided into quadrupedes, or beaſts; reptiles, which have many feet, and ſerpents which have no feet at all.

Inſects, which in their ſeveral changes belong to ſeveral of the before-mentioned diviſions, may be conſidered together as one great tribe of animals. They are called inſects, from a ſeparation in the middle of their bodies, whereby they are as it were cut into two parts, which are joined together by a ſmall ligature, as we ſee in waſps, common flies, and the like.

Beſides all theſe, there are ſome animals that are not perfectly of theſe kinds, but placed as it were in the middle betwixt them, by having ſomething of both; as beaſts and birds in them.

The greateſt part of animals have five ſenſes, viz. ſeeing, hearing, ſmelling, taſting, and feeling. Some reptiles of the earth, and ſome of the aquatics, want one or more of the ſenſes which are in perfect animals, as worms, oyſters, cockles, &c.

One would wonder to hear ſceptical men diſputing for the reaſon of animals, and telling us it is only our pride and prejudices that will not allow them the uſe of that faculty. Reaſon ſhews itſelf in all occurrences of life: whereas the brute makes no diſcovery of ſuch a talent, but in what immediately regards his own preſervation or the continuance of his ſpecies. Animals, in their generation, are wiſer than the ſons of men: but their wiſdom is confined to a few particulars, and lies in a very narrow compaſs. Take a brute out of his inſtinct, and you find him wholly deprived of underſtanding.

Animals conſiſt of ſolids, or firm parts, as fleſh, bones, membranes, &c. and fluids, as blood, &c.

The ſolids are mere earth, bound together by ſome oily humour; and accordingly are deducible by fire into ſuch earth again.

Thus a bone, being perfectly purged of its moiſture by calcination, is found a mere earth, which the leaſt force will crumble into duſt, for want of the natural gluten; yet the ſame bone, by immerging it in water or oil, becomes firm and ſtrong again, and more ſo in oil than water. And thus cupels will ſuſtain the utmoſt effects of fire.

The parts of animals are diſtinguiſhed from thoſe of vegetables by two circumſtances: the firſt, that when burnt they are found perfectly inſipid, all animal ſalts being volatile, and flying off with heat; the contrary of this is found in vegetables, which conſtantly retain ſome fixed ſalt in all their aſhes.

The ſecond, that no true acid is contained in any animal juice; nor can any acid ſalt be extracted from the ſame; the contrary of which is found in all vegetables.

Yet are animals reconverted into their vegetable nature by putrefaction.

Animals make the ſubject of that branch of natural hiſtory called zoology.

The ſtructure of animals, with their diſorders, remedies, &c. make the ſubject of anatomy, medicine, &c.

As to the ſtructure of animals, it is obſerved that the make of every kind of animal is different from every other kind; and yet there is not the leaſt turn in the muſcles or twiſt in the fibres of any one, which does not render them more proper for that particular animal's way of life, than any other caſt or texture of them would have been.

Animal, uſed adjectively, ſignifies ſomething belonging to, or partaking of, the nature of animals.

Animal *Oeconomy.* See Oeconomy.

Animal *Oil.* See the article Oil.

Animal *Secretion*, the ſeparation of the ſeveral juices of the body from the blood. See Secretion.

Animal *Spirits*, a very ſubtile fluid ſuppoſed to be ſeparated from the brain, and thence diffuſed into all parts of the body for the performance of all animal and vital functions. See the article Spirit.

ANIMALCULE, a minute animal, ſcarce, if at all, viſible to the naked eye.

The word is Latin, *animalculum*, a diminutive of animal.

Animalcules, though ſo very minute as to be only ſeen by the aſſiſtance of the microſcope, are vaſtly more numerous than any other part of the animal creation. They have been diſcovered in moſt liquors, in ſeveral of the chalybeat as well as in common water: in oats, barley, wheat, peas, &c. and in the puſtules of the itch.

ANIMATED, ſomething inſpired with life, or that exhibits marks of being inſpired by ſome ſpirit or ſoul.

Animated *Power*, in mechanics, implies a man, or other animal, in contradiſtinction to ſprings, water, wind, &c.

Animated *Needle*, one touched with a loadſtone, or magnet. See Magnet.

ANIME, or *Gum* Anime, in natural hiſtory, is a kind of gum, or rather reſin, of a friable ſubſtance, inflammable, and ſoluble in oil. There are two kinds of this gum-reſin, diſtinguiſhed by the epithets of oriental and occidental.

The oriental or Ethiopian anime, called by the Portugueſe animum and aniimum, and in the ſhops gum anime, is a dry and ſolid reſin, brought to us in large cakes or maſſes, of an irregular figure, and of a very uncertain colour; ſome of them are greeniſh, ſome reddiſh, ſome brown, and ſome of the colour of myrrh; they all agree in this, however, that they are moderately pellucid, of a tolerable compact texture, light and eaſily powdered, of a fragrant ſmell, very inflammable, and of a reſinous and ſomewhat bitter taſte. This, which is the genuine and true anime, is now very rare in the ſhops. It is brought, as Garcias informs us, only from Ethiopia; but the occidental kind, or reſin of the courbaril, is what is univerſally received in its place. It has been ſuppoſed by many, that this Ethiopian or true anime was known to the ancient Greeks. Some have ſuppoſed that Dioſcorides meant this reſin by the name of myrrha minia; and many arguments have been advanced in favour of the opinion: but the reſins themſelves are ſo like one another, and the deſcriptions the Greeks have left us of them is ſo ſhort and imperfect, that it is impoſſible to affirm any thing on this head with any tolerable degree of certainty. We are not yet informed what the tree is that produces the Ethiopian anime. Herman is of opinion, that it is the ſame that yields the occidental kind, only growing in a different climate; but this is no more than a conjecture.

The occidental anime is a whitiſh, dry, and ſolid reſin, ſomewhat reſembling frankincenſe in colour. It is often of a fine yellowiſh white, between that of frankincenſe and maſtich, and in the pureſt pieces is very clean and tranſparent; in general, however, it is much inferior to the oriental in theſe reſpects. It is moderately heavy, friable, and ſomewhat oleaginous to the touch. It is extremely fragrant, eſpecially when burnt, and is of a reſinous, acrid, and ſomewhat bitteriſh taſte. It is brought to us from many parts of America, particularly from New Spain and the Braſils. The natives call it joticacica and jetaicica. Our people, from their name of the tree, vulgarly call it reſin of courbaril.

Whatever might be the caſe in regard to the Ethiopian anime, we may be very well aſſured, that this was not known to the Greeks. The tree which produces it is one of the arbores ſiliquoſæ of Mr. Ray. It is deſcribed by Caſpar Bauhine, under the name of arbor ſiliquoſa ex Virginia lobo fuſco ſcabro; and by Plumier, under that of courbaril bifolia flore pyramidato. It grows to a very great height; its wood is ſolid, and of a fine grain, of a reddiſh colour, and very durable, and ſerves them for many of their better works. The leaves are like thoſe of our bay-tree, but thicker, and they grow conſtantly two together on every ſtalk; they are of a ſhining green, and, if held up to the light, ſeem to be perforated with innumerable little holes in the manner of the leaves of St. John's-wort. The flowers ſtand in cluſters or tufts towards the tops of the branches; they are of the papilionaceous kind, like thoſe of our vetches, and of a purpliſh colour; they are ſucceeded by a kind of pods ſix inches long, and an inch and a half broad, compreſſed ſideways, and raiſed into two ridges on the back. The fruit, when ripe, does not open lengthways into two halves, as the generality of pods of this ſhape do; it remains entire, and contains in it, among a multitude of irregular fibres, four or five ſeeds larger than the common pine-kernels, otherwiſe like them. This tree is common in moſt parts of America; and the fruit ripens in May and June, when it falls from the trees, and is picked up by the natives, who are fond of the farinaceous ſubſtance that is among the fibres within. The trunk of the tree exſudates the reſin here deſcribed in very conſiderable quantities, without being wounded for it; the fineſt lumps of it are white, or of a pale yellow, and much reſemble amber.

Anime, in heraldry, a term uſed when the eyes of any rapacious creature are borne of a different tincture from that of the creature itſelf.

ANINGA, in commerce, the name of a root growing in the Antilles iſlands, nearly reſembling the china root. It is uſed in the ſugar works for refining the ſugar.

ANISE, *Aniſum*, in botany, a ſmall annual umbelliferous herb, producing roundiſh ſtriated ſeeds, flatted on one ſide, and pointed at one end; of a pale colour inclining to green. The upper leaves are divided into five ſegments; but the lower are entire, roundiſh, and ſerrated about the edges.

This plant, which is ſaid to be a native of Egypt and Syria, is cultivated in the ſouthern parts of Europe. It is alſo raiſed in ſome of our gardens, but ſeldom brings its ſeed to perfection. The ſeed brought from Spain are reckoned the beſt.

Anniſeeds have an aromatic ſmell, and a pleaſant warm taſte, accompanied with a ſmall degree of ſweetneſs. They are in common uſe as a warm carminative, and ſuppoſed to be the moſt effectual of all the warm ſeeds.

They give out all their virtue to rectified ſpirits, which become of a bright lemon colour, and taſte very agreeably. Infuſed in water they impart a little of their ſmell, but ſcarcely any taſte: in diſtillation they give over the whole of their flavour, the remaining decoction having neither the ſmell nor the taſte of the anniſeeds.

An eſſential oil ariſes with the water, in a conſiderable quantity, above an ounce having been extracted from three pounds of the ſeed. This oil is of a yellowiſh colour, and congeals into a butyraceous white concrete, even when the air is not ſenſibly cold. Its ſmell, which exactly reſembles that of the anniſeeds, is extremely durable and diffuſive; and its taſte milder, and leſs pungent than that of almoſt any other diſtilled vegetable oil. It is recommended chiefly in diſorders of the breaſt; but is ſaid to be leſs effectual in flatulencies, than the ſeeds in ſubſtance.

Anise *Stellatum*, ſtellated aniſe, is the fruit or ſeed veſſel of a ſmall tree growing in Tartary, China, and the Philippine iſlands. It conſiſts of ruſty brown coloured hard wrinkled capſules, about half an inch in length, joined together by baſes, to the number of ſix or more, in the form of a ſtar; each of which include one ſeed or kernel, gloſſy, and of the colour of linſeed externally, and white internally.

The huſks have a fragrant ſmell, and a ſweetiſh warm aromatic taſte, reſembling thoſe of the common anniſeeds, but ſtronger and more agreeable. They have alſo the ſame virtues, and might be given with advantage in the ſame intentions.

ANKER, a liquid meaſure at Amſterdam, containing about thirty-two gallons Engliſh.

ANNALES, a ſpecies of hiſtory, wherein events are related in the chronological order they happened.

It differs from a perfect hiſtory, in being only a meer relation of what paſſes every year, as a journal is of what paſſes every day; whereas hiſtory relates not only to the tranſactions themſelves, but alſo the cauſes, motives, and ſprings of ſuch actions. Annales require brevity only; hiſtory demands ornament.

Cicero informs us that the pontifex maximus, in order to preſerve the memory of events, wrote what paſſed each year on tablets, which were expoſed to public inſpection in his own houſe. Theſe tablets were called *annales maximi*; and hence the writers who imitated this ſimple method of writing were ſtiled annaliſts.

ANNATES, among eccleſiaſtical writers, implies the firſt year's revenue of a ſpiritual living.

Theſe annates were formerly given to the pope; but at the Reformation they were veſted in the king. Queen Anne, however, reſtored them to the church, by appropriating them to the augmentation of ſmall livings.

ANNEALING, or Nealing, an operation performed on glaſs, earthen-ware, &c. in a particular oven or furnace erected for that purpoſe. See the article Nealing.

Annealing *of Glaſs*, *Iron*, *Steel*, *&c.* See Glass, Iron, Steel, &c.

ANNE, or *St.* Anne's *Day*, a feſtival obſerved in the Greek and Latin churches, in honour of Anne or Anna, mother of the Virgin Mary. It is celebrated by the former on the ninth of December, and by the latter on the twenty-ſixth of July.

ANNEXATION, in law, implies the uniting lands or rents to the crown.

ANNI *Nubiles*, in law, ſignifies the marriageable age of a woman, viz. after ſhe has reached her twelfth year.

ANNIENTED, in law, imports annulled or made void.

ANNIHILATION, the act of reducing any created being to nothing, and ſtands oppoſed to creation.

The word is formed from the Latin, *ad*, to, and *nihilum*, nothing.

ANNIVERSARY, the annual return of any remarkable day.

The word is formed from the Latin, *annus*, a year, and *verto*, to turn.

Formerly anniverſary days particularly denoted thoſe days on which an office was performed for the ſouls of the deceaſed, or the martyrdom of the ſaints was celebrated in the church.

ANNO DOMINI, the year of your Lord, the computation of time from our Saviour's incarnation. See EPOCHA.

ANNOMINATION, in rhetoric; ſee PARONOMASIA.

ANNOTATION, in matters of literature, a brief commentary, or remark on a book or writing, in order to clear up ſome paſſage, or draw ſome concluſion from it.

ANNOTATION, among phyſicians, implies the beginning of a febrile paroxyſm, when the patient begins to ſhiver, yawn, and ſtretch.

ANNOTTO, in dying, an elegant red colour, formed from the pellicles of the ſeeds of a tree common in South-America. It is alſo called orlean, and roucou.

The manner of making annotto is as follows: The red ſeeds, cleared from the pods, are ſteeped in water for ſeven or eight days or longer, till the liquor begins to ferment; then ſtrongly ſtirred, ſtamped with wooden paddles and beaters, to promote the ſeparation of the red ſkins: this proceſs is repeated ſeveral times till the ſeeds are left white. The liquor, paſſed through cloſe cane ſieves, is pretty thick, of a deep red colour, and a very ill ſmell: in boiling, it throws up its colouring matter to the ſurface in form of ſcum, which is afterwards boiled down by itſelf to a due conſiſtence, and made up while ſoft into balls.

The annotto, commonly met with among us, is moderately hard and dry, of a brown colour on the outſide, and a dull red within. It is difficultly acted upon by water, and tinges the liquor only of a pale browniſh yellow colour. In rectified ſpirit of wine, it very readily diſſolves, and communicates a high orange or yellowiſh red. Hence it is uſed as an ingredient in varniſhes, for giving more or leſs of an orange caſt to the ſimple yellows. Alkaline ſalts render it perfectly ſoluble in boiling water, without altering its colour. Wool or ſilk boiled in the ſolution, acquire a deep, but not a very durable, orange dye. Its colour is not changed by alum or by acids, any more than by alkalies; but when imbibed in cloth, it is diſcharged by ſoap, and deſtroyed by expoſure to the air.

Mr. Pott, in the Berlin Memoirs for the year 1752, mentions a very extraordinary property of this concrete: "With the vitriolic acid, it produces a blue colour, of "extreme beauty, but with this capital defect, that all "ſalts and liquors, even common water, deſtroy it." The ſpecimen of annotto which I examined was not ſenſibly acted on by ſpirit of vitriol; it received no change in its own colour, and communicated none to the liquor: nor did any viſible change enſue upon dropping the acid into tinctures of annotto made in water or in ſpirit.

Labat informs us, that the Indians prepare an annotto greatly ſuperior to that which is brought to us, of a bright ſhining red colour, almoſt equal to carmine: that, for this purpoſe, inſtead of ſteeping and fermenting the ſeeds in water, they rub them with the hands, previouſly dipt in oil, till the pellicles come off, and are reduced into a clear paſte, which is ſcraped off from the hands with a knife, and laid on a clean leaf, in the ſhade, to dry. De Laet, in his notes on Marcgrave's Natural Hiſtory of Brazil, mentions alſo two kinds of annotto; one of a permanent crimſon colour, uſed as a fucus, or paint for the face; and another, which gives a colour inclining more to that of ſaffron. This laſt, which is our annotto, he ſuppoſes to be a mixture of the firſt ſort with certain reſinous matters, and with the juice of the root of the tree. *Lewis's Notes upon Neumann's Chemiſtry.*

ANNUA *Penſione*, in law, an old writ for granting an annual penſion to one of the king's chaplains.

ANNUAL, in a general ſenſe, is an epithet applied to any thing that returns every year, or that is performed in that ſpace of time.

ANNUAL *Equation*, in aſtronomy; ſee the article EQUATION.

ANNUAL, or rather ANNUEL, in the Scottiſh law, implies a yearly revenue or rent, payable at the two great terms Whitſuntide and Martinmas.

ANNUENTES *Muſculi*, in anatomy; ſee the article RECTI *Interni Minores*.

ANNUITY, a yearly rent or revenue, paid either for term of life, or of years, or in fee, and for ever.

In common law, the difference between a rent and an annuity, conſiſts in this, that rent is payable out of land; whereas an annuity charges only the perſon of the grantor; and that, for the recovery of a rent, an action lies: whereas for that of an annuity, there only lies a writ of annuity againſt the grantor, his heirs and ſucceſſors. Add, that annuities are never taken for aſſets, as being no freeholds in law.

For the computation of the value of annuities in arrears on lives, in perpetuity, &c. ſee INTEREST *Simple* and *Compound*.

ANNULAR, in a general ſenſe, implies ſomething in the form of a ring.

The word is formed from the Latin, *annularis*, and derived from *annulus*, a ring.

ANNULAR, in anatomy, is an epithet applied to ſeveral parts of the human body: thus the ſecond cartilage of the larynx is called the annular cartilage; the ligament that encompaſſes the wriſt, and ties the bones together, is termed the annular ligament; and a protuberance of the medulla oblongata is ſtiled the annular proceſs.

ANNULAR is alſo a peculiar name for the fourth finger.

ANNULET, in architecture, ſignifies a ſmall ſquare member in the Doric capital, uuder the quarter round. See CAPITAL.

ANNULET is alſo uſed to imply a narrow flat moulding, common to various parts of the columns, particularly their baſes, capitals, &c. Vitruvius calls it a fillet; Palladio, a liſtel or cincture; Scammozzi, a ſupercillium, liſt, tinea, eye-brow, ſquare, and rabbit. Such confuſion have artiſts made by calling the ſame member by different names.

ANNULET, in heraldry, is a mark of diſtinction proper to the fifth brother of a family.

ANNULLING, a term ſometimes uſed for cancelling, or rendering a deed, ſentence, &c. void, and of no effect.

ANNUNCIADA, an order of knighthood in Savoy, originally inſtituted by Amadeus I. in the year 1409, and called by the founder, the knot of love. The collar conſiſted of fifteen links interwoven with one another, in the form of a true lover's knot; and the motto, F.E.R.T. *fortitudo ejus Rhodum tenuit.* But Amadeus VIII. changed the name to that of Annunciada, and inſtead of the image of St. Maurice, which was appended to the collar, placed that of the Virgin Mary. At the ſame time he ſubſtituted the words of the Angel's ſalutation, inſtead of thoſe in the above motto.

ANNUNCIADES, ſeveral religious orders inſtituted in honour of the annunciation.

The firſt order of this kind was founded by ſeven merchants at Florence, in 1232. The ſecond was a nunnery at Bourges, founded by Joan, queen of France, after her divorce from Lewis XII. The third was a nunnery founded by a Genoeſe lady in the year 1600. The fourth, a friary, founded by cardinal Torrecremata, at Rome.

ANNUNCIATION, a feſtival celebrated by the church on the twenty-fifth of March, in memory of the annunciation, or tidings, brought by the angel Gabriel to the Virgin Mary, of the incarnation of Chriſt.

The feaſt of this annunciation appears to be of very great antiquity. There is mention made of it in a ſermon, which goes under the name of Athanaſius. Others carry it up to the time of Gregory Thaumaturgus, becauſe there is a ſermon likewiſe attributed to him upon the ſame ſubject. But the beſt critics reject both theſe writings as ſpurious. However, it is certain, this feſtival was obſerved before the time of the council of Trullo, in which there is a canon forbidding the celebration of all feſtivals in Lent, excepting the Lord's day, and the feaſt of the annunciation: ſo that we may date its original from the ſeventh century.

ANODYNE, among phyſicians, ſignifies a medicine that mitigates or removes pain.

The word is compounded of the Greek, α, priv. and ὠδυνη, pain.

There are two ſpecies of anodynes, diſtinguiſhed by the epithets proper and improper. The former are ſuch as mitigate the pain by removing the cauſe. The latter that alleviate it for a time by ſtupifying the ſenſes. The proper anodynes are called paregorics; and the improper opiates, and narcotics. See the articles PAREGORICS, OPIATES, and NARCOTICS.

ANOMALISTICAL *Year*, in aſtronomy, ſignifies the time that the earth takes up in paſſing through her orbit, and is generally called the periodical year. See the article YEAR.

ANOMALOUS, in a general ſenſe, is applied to whatever is unequal, irregular, or that deviates from the rule obſerved by ſimilar things in ſimilar caſes.

The word is formed from the Greek, α, priv. and ομαλος, equal.

ANOMALOUS *Pulſe*, among phyſicians, implies a pulſe whoſe ſtrokes are unequal with regard to ſtrength.

ANOMALOUS *Verbs*, in grammar, are ſuch as are irregularly conjugated, or formed in a manner different from the general rules.

ANOMALY, in grammar, implies an irregularity or a deviation from the common rules.

ANOMALY, in aſtronomy, is the diſtance of a planet from the aphelion or apogee; or it is an irregularity in the motion of a planet, whereby it deviates from the aphelion or apogee.

Kepler diſtinguiſhes three kinds of theſe anomalies; mean, eccentric, and coequate, or true.

Mean ANOMALY, in the old aſtronomy, is the diſtance of a planet's mean place from the apogee.

In the modern aſtronomy, it is the time wherein the planet moves from its aphelion, to the mean place or point of its orbit. Thus, let A O B (pl. XII. *fig.* 10.) be the orbit of a planet *n* revolving therein, about S, the ſun placed in one of the foci, A C the ſemi tranſverſe axis, C O the ſemi-conjugate, and *n* the place of the planet at any given time, after or before its paſſing A, the aphelion. Now from *n* draw *n* P perpendicular to A B, and produce P *n* to E in the periphery of the circumſcribing circle A E B *s* A, draw the radius C E, and from S let fall the perpendicular S D upon E C produced, take the arch E H equal to the right line S D, and draw H C; then will A H, the meaſure of the angle A C H, repreſent the mean anomaly of the planet in the point *n*, and is proportional to the time of its moving from A to *n*. To prove this, draw E S and S *n*; then the ſector E C H being equal to the triangle E C S, A C H A will be equal to A E S A; for the former of thoſe areas is compounded of the ſector A C E, and E C H, and the latter of the ſame ſector, and the triangle E C S: wherefore, ſince the area A S E A, is to A E B C A, half the circle, as the elliptical area A *n* S A, to the ſemi-ellipſis A *n* B C A, by a well known relation of the two curves; if, inſtead of A E S A, its equal be ſubſtituted, we ſhall have, as A C H A : A E B A :: A *n* S A : A *n* B A; but A C H A is to A E B A, as the arch A H to A E B, the ſemi-circumference; and therefore it will be as A *n* B A : A *n* S A :: A E B : A H. Wherefore, ſince the areas A *n* B A, A *n* S A, deſcribed by radii drawn to S, the center of force, are as the times of their deſcription, it will be as the time of deſcribing A *n* B A, or that of half one revolution is to the given time of deſcribing A *n* S A, ſo is A E B to A H, which therefore is the mean anomaly in this poſition, or the arch proportional to the time of the planet's moving through A *n*.

ANOMALY *of the Excentric*, or *of the Center*, in the ancient aſtronomy, is an arch of the zodiac, terminated by the line of the apſides, and the line of the mean motion of the center.

In the new aſtronomy, it is an arch A E of the excentric circle A E B, cut off by a right line P *n* E, drawn perpendicular to the tranſverſe diameter A B of the orbit.

ANOMALY *Coequate*, or *True*, is the diſtance of the ſun from his apogæum, or a planet from its aphelium, where it is ſeen from the ſun; that is, it is the angle A S *n* at the ſun, which the planet's diſtance from the aphelium A appears under. Ptolemy calls this *the angle of the true motion*, and ſome *the angle of the ſun.*

It is a difficult, and at the ſame time a very uſeful, problem to find directly the true anomaly from the mean one given; or, which is the ſame thing, to find the poſition of a right line S *n* paſſing through the focus S of a given ellipſis, which ſhall cut off an area *n* S A by its motion, being to the area of the whole ellipſis in a given ratio, viz. in the ratio of the periodic time of a planet deſcribing the ellipſis to another given time; which being found, the point *n*, or place of the planet at that time will be had.

There are ſeveral methods of ſolving this uſeful problem, which was firſt propoſed by the learned Kepler, though indeed he was never maſter of a direct method of ſolving it, as himſelf expreſly owns; but he did it indirectly by the *Rule of Falſe*, as may be ſeen in his *Epitom. Aſtron. Copernic.* Wolfius and Dr. Wallis firſt gave the geometrical ſolution thereof, by means of the protracted cycloid: ſo has Sir Iſaac Newton too in Prop. 31, lib. 1. *Princip. Mathem. Philoſ. Nat.* Theſe are indeed very ingenious, but not adapted for the purpoſe of an aſtronomer; and therefore Sir Iſaac Newton gave other ſolutions by ſeries's; the ſame has been done by Dr. Gregory in his *Aſtron.* lib. 3. alſo by Dr. Keil in his *Prælection. Aſtron* p. 375.

The moſt uſeful and exact method for finding the place of a planet in its orbit, is from a correction of Ward's Hypotheſis, by means of one or more equations applied to the motion about the upper focus. This elegant inveſtigation, as given by that late excellent mathematician Mr. Thomas Simpſon, in his Miſcellaneous Tracts, is as follows.

Let A B P C (pl. XII. *fig.* 11.) be the ellipſis in which the planet revolves about the ſun in the lower focus S; let F be the upper focus, and M and *m* any two places of the planet indefinitely near to each other, and let F M, F *m*, S M, S *m*, be drawn, as likewiſe M N, perpendicular to the greater axis A P: from the center F, with the radius F D = 1, let the circumference of a circle D E *e* be deſcribed, and from its interſection with F M draw E H perpendicular to A P: put A O (= O P) = a, O B (= O C) = b, O F (= O S) = c, F M = u, F H = x, E H = y, D E = z, and E *e* = $\dot{z}$, then S M being (= A P − F M) = $2a-u$, by the nature of the ellipſis, and F N $\left(= \mathrm{FH}\times\frac{\mathrm{FM}}{\mathrm{FE}}\right) = ux$, we have, by a known property of triangles $\overline{\mathrm{SM}+\mathrm{FM}}\times\overline{\mathrm{SM}-\mathrm{FM}}$ ($2a\times\overline{2a-u} = 2\,\mathrm{SF}\times\mathrm{ON}$ ($4c\times\overline{c+ux}$): from which equation u (F M) is found $= \frac{a^2-c^2}{a+cx} = \frac{bb}{a+cx}$ (becauſe $bb = aa-cc$): whence S M ($=2a-u$) is alſo had in terms of x, being $= \frac{aa+cc+2acx}{a+cx}$.

Now the area E F *e* being expreſſed by $\frac{1}{2}\dot{z}$ (= F E × $\frac{1}{2}$ E *e*) we have FE^2 (1) : FM^2 :: $\frac{1}{2}\dot{z}$: the area M F *m* $= \frac{1}{2}\dot{z}\times\mathrm{FM}^2$. Therefore, the angle S M *m* being equal to F M A, or F *m* A (by the nature of the curve) we alſo have F M × M *m* : S *m* × *m* M (or F M) : S M : : the area ($\frac{1}{2}\dot{z}\times\mathrm{FM}^2$) of the triangle F M *m* : the area of the triangle S M *m* $= \frac{1}{2}\dot{z}\times\mathrm{FM}\times\mathrm{SM}$ (Euc. 23. 6.)

$$= \frac{\frac{1}{2}b^2\dot{z}\times\overline{a^2+c^2+2acx}}{\overline{a+cx}^2} = \frac{1}{2}b^2\dot{z} + \frac{\frac{1}{2}b^2c^2\dot{z}\times\overline{1-xx}}{\overline{a+cx}^2}$$

$$= \frac{1}{2}b^2\dot{z} + \frac{\frac{1}{2}b^2c^2y^2\dot{z}}{\overline{a+cx}^2} = \text{the fluxion of the area ASM.}$$

In order to find the fluent hereof, let $\frac{1}{\overline{a+cx}^2}$ be reſolved into the ſeries $a^{\frac{1}{2}} - \frac{2cx}{a^3}$, and (whereof the two firſt terms will here be ſufficient) by which means our fluxion will become $\frac{1}{2}\, b^2 \dot{z} + \frac{\frac{1}{2} b^2 c^2 y^2 \dot{z}}{a^2} - \frac{b^2 c^3 x y^2 \dot{z}}{a^3}$, which, becauſe $y\dot{z} = -\dot{x}$, and $x\dot{z} = \dot{y}$, will be reduced to $\frac{1}{2}\, b^2 \dot{z} + \frac{b^2 c^2}{2a^2} \times -y\dot{x} - \frac{b^2 c^3 y^2 \dot{y}}{a^3}$; whoſe fluent will therefore be truly expreſſed by $\frac{1}{2}\, b^2 z + \frac{b^2 c^2}{2a^2} \times$ area D H E $- \frac{b^2 c^3 y^3}{3a^3}$, or $\frac{1}{2}\, b^2 z + \frac{b^2 c^2}{2a^2} \times \overline{\frac{1}{2} z - \frac{1}{2} x y} - \frac{b^2 c^3 y^3}{3a^3}$ (becauſe the area D H E $= \frac{1}{2}$ D E × D F $- \frac{1}{2}$ H F × E H $= \frac{1}{2} z - \frac{1}{2} x y$). This expreſſion, when M coincides with P, and z is = the ſemi-circumference D E K $(=p)$ will become $\frac{b^2 p}{2} + \frac{b^2 c^2 p}{4aa} = \frac{b^2 d p}{2}$ (ſuppoſing $d = 1 + \frac{cc}{2aa}$) = the area of the ſemi-ellipſis A B P. Therefore we have, as $\frac{b^2 dp}{2} : \frac{b^2 dz}{2} - \frac{b^2 c^2 xy}{4aa} - \frac{b^2 c^3 y^3}{3a^3}$ (= the area A S M) :: p (= the length of an arch of 180°) : $z - \frac{c^2 xy}{2a^2 d} - \frac{2c^3 y^3}{3a^3 d}$ = the length of an arch (A) expreſſing the planet's mean anomaly; from which equation, $z = \mathrm{A} + \frac{c^2 xy}{2a^2 d} + \frac{2c^3 y^3}{3a^3 d} = \mathrm{A} + \frac{c^2}{4a^2 d} \times \overline{\text{ſin. } 2z} + \frac{2c^3}{3a^3 d} + \overline{\text{ſin. } z}|^3$ (becauſe xy, or coſine z × ſine $z = \frac{1}{2}$ ſin. $2z$: where the two laſt terms being very ſmall in compariſon of the others (and, therefore, z nearly = A), we may, inſtead of ſin. z and ſin. $2z$, ſubſtitute ſin. A and ſin. 2 A; by which means we have $z = \mathrm{A} + \frac{c^2}{4a^2 d} \times \text{ſin. } 2\mathrm{A} + \frac{2c^3}{3a^3 d} \times \overline{\text{ſin. A}}|^3$. From whence it appears that, in order to have the angle A F M at the upper focus, the mean anomaly (A) of the planet at the time given, muſt be increaſed by the quantity or correction $\frac{c^2}{4a^2 d} \times \text{ſin. } 2\mathrm{A} + \frac{2c^3}{3a^3 d} \times \overline{\text{ſin. A}}|^3$.

But to expreſs the value of this correction in ſeconds of a degree (which in practice is the moſt commodious) it will be, as 3.1416 (the length of an arch of 180 degrees) is to 648000 (the number of ſeconds in that arch) ſo is $\frac{cc}{4a^2 d} \times \text{ſin.} 2\mathrm{A} + \frac{2c^3}{3a^3 d} \times \overline{\text{ſin. A}}|^3$ to $51567 \times \frac{c^2}{a^2 d} \times \text{ſin. } 2\mathrm{A} + 137513 \times \frac{c^3}{a^3 d} \times \overline{\text{ſin. A}}|^3$ = the number of ſeconds in the ſaid correction, the logarithm of the latter term of which will therefore be $= 5.1383 -$ log. $d + 3$ log. $\frac{c}{a} + 3$ log. ſin. A; and that of the former $= 4.7123 -$ log. $d + 2$ log. $\frac{c}{a} +$ log. ſin. 2 A. But, to render theſe expreſſions ſtill more convenient for practice, the log. of d, by reaſon of its ſmallneſs, may be either entirely neglected, or elſe ſo aſſumed, to be nearly a mean of what it is known to be in the planetary orbits: accordingly, by aſſuming the excentricity $c = \frac{8}{100}$ of the mean diſtance, (which is a ſmall matter leſs than the excentricity of Mars, but ſomething greater than thoſe of the Moon, Saturn, and Jupiter) the value of d $\left(= 1 + \frac{c^2}{2aa}\right)$ will be =1,0032, and its logarithm = 0,0014. Whence the log. of the former part of our correction, by ſubſtituting this value, will be $\overline{5.1369 + 3}$ log. $\frac{c}{a} + 3$ log. ſine A $= 3 \times 1.7123 +$ log. $\frac{c}{a} +$ log. ſin. A and that of the latter $= 4.7109 + 2$ log. $\frac{c}{a} +$ log. ſin. 2 A: which, expreſſed in words at length, give the following

PRACTICAL RULES.

1°. To the ſum of the conſtant logarith. 1.7123, and the log. of the excentricity in parts of the mean diſtance, add the log. ſine of the mean anomaly, the ſum (rejecting the radius) being tripled, will give the log. of the firſt equation (in ſeconds) to be added to the mean anomaly.

2°. To the ſum of the conſtant log. 4.7109, and twice the log. of the excentricity, add the log. ſine of twice the mean anomaly, the ſum (rejecting the radius) will be the log. of the ſecond equation, to be added or ſubtracted, according as the mean anomaly is leſs, or greater than 90 degrees.

Here, and in what follows, the anomaly is to be always reckoned from, or to the aphelion, the neareſt way, in which the ſeconds may be omitted in computing the propoſed corrections; which corrections being made, the true anomaly, or angle at the lower focus, will be had from the common proportion, by ſaying, As the aphelion diſtance is to the perihelion-diſtance, ſo is the tangent of half the mean anomaly, thus corrected, to the tangent of half the true anomaly ſought.

As an example of the uſe of the method here laid down, let the excentricity be ſuppoſed = 0.048219 (being that aſſigned by Dr. Halley to the orbit of Jupiter) and let the mean anomaly be 45°.

Then, log. excent. — $\bar{2}$.6832 2 log. excent. $\bar{3}$.3664
+ conſt. log. — — 1.7123 + conſt. log. 4.7109
= log. for 1ſt equ. — $\bar{0}$.3955 = log. for 2d equ. 2.0773
log. ſin. anom. — — 9.8494 log. ſin. 2 anom. 10.0000
0.2449 2d equ. = 119½″ 2.0773
firſt equa. = 5½″ — 0.7347
From 1.978537 = log. of perihelion-diſ. 0.951781
Subſtr. 0.020452 = log. of the aphelion-diſ. 1.048219
the rem. $\overline{1}$.958085 will be a (3d) conſt. log. for this orbit, to which add 9.617596 = log. tang. ½ cor. anom. 22°. 31′. 2½″
ſo ſhall 9.575681 = log. tang. ½ true anom. 20°. 37′. 40″
whoſe double 41°. 15′. 20″. is therefore the true anomaly required.

The ſame excentricity being retained, let the mean anomaly be now ſuppoſed 120 degrees.

Then, log. ſin. anom. 9.9375 log. ſin. 2 anom. 9.9375
log. for firſt equation 0.3955 log. for 2d equat. 2.0773
0.3330 2d equat. = 103½″ 2.0148
firſt equat. = 10″ 0.9990

Hence 120° + 10″ − 1′ 43½″ = 119° 58′ 26½″ = the cor. anomaly.

Therefore log. tang. ½ cor. anom. 59° 59′ 13¼″ 10.238331
+ third conſt. log. for this orbit — —— —— 1.958085
= log. tang. ½ true anom. 57° 32′ 10″ —— 10.196416
Whence the anomaly itſelf is given = 3ˢ. 25°. 4′. 20″.

If the excentricity be aſſumed = 0.066777 (being the greateſt that Dr. Halley gives to the lunar orbit) the two conſtant logarithms, to be added to the ſines of the mean anomaly and of its double, will be 0.5369 and 2.3601: whence, if the ſaid anomaly be taken = 50° (at which, according to the Doctor's Table, *pro expediendo calculo æquationis centri lunæ*, the whole correction is a maximum) the former part of the ſaid correction will be found = 18½″, and the latter part = 225½″: therefore the ſum of both is 244″, or 4′, 4″, agreeing exactly with the quantity given in the table. And in the very ſame manner the proper corrections correſponding to other anomalies and excentricities may be computed; the error never amounting to above a ſingle ſecond in any of the planets, except Mars and Mercury: in the place of Mars, the greateſt error will be two or three ſeconds; and in that of Mercury about as many minutes. As to the Earth and Venus, the ſecond equation alone will be ſufficient to give their places to leſs than a ſecond.

ANOMOEANS, in eccleſiaſtical hiſtory, the name by which the pure Arians were diſtinguiſhed in the fourth century, in contradiſtinction to the Semi-Arians.

The word is formed from the Greek, ανομοιος, different, diſſimilar: for the pure Arians aſſerted, that the Son was of a nature different from, and in nothing like, that of the Father: whereas the Semi-Arians acknowledged a likeneſs of nature in the Son; at the ſame time that they denied, with the pure Arians, the conſubſtantiality of the word.

The Semi-Arians condemned the Anomæans in the council of Seleucia, and the Anomæans in their turn condemned the Semi-Arians in the councils of Conſtantinople and Antioch, eraſing the word ομοῖος, like, out of the Formula of Rimini, and that of Conſtantinople.

ANONA, in botany, the name of a genus of plants, whoſe perianthum is compoſed of three cordated, hollowed, and ſharp-pointed leaves; the ſtamina are ſcarce viſible; but the antheræ numerous: the fruit is a large berry, of an oval figure, covered with a ſquamoſe punctuated bark: the ſeeds are numerous, hard, of an oblong figure, and placed circularly.

ANONIS, *Reſt Harrow*, in botany, the name of a plant, whoſe roots are above a foot long, creep every way, and not eaſily broken. The ſtalks which lie on the ground, are ſlender, tough, reddiſh, hairy, and full of prickles; they are beſet with roundiſh leaves, placed three together alternately, ſlightly crenated, hairy, of a dark green colour, and glutinous to the touch. The flowers are papilionaceous, of a light purple, or fleſh colour, and grow in ſpikes at the top of the branches. The piſtil is near a quarter of an inch long, and conſiſts of one bivalved flat capſule, containing a ſingle ſeed in the ſhape of a kidney.

Reſt harrow is accounted deterſive, good to open obſtructions of the liver, and to cure the jaundice. Some affirm it is a diuretic, and proper in ſuppreſſion of the urine; but it is at preſent rarely uſed.

ANONYMOUS, ſomething without a name.

The word is Greek, ανωνυμος, and compounded of α, priv. and ονομα, a name.

It is generally applied to ſuch books as are publiſhed without the name of the author; and to ſuch authors whoſe names are unknown.

ANOREXY, among phyſicians, implies a want of appetite, or a loathing of food.

The word is Greek, ανορεξια, and compounded of α, priv. and ορεγομαι, to covet or deſire.

The anorexy is either an eſſential diſeaſe, proceeding from a fault in the ſtomach, or derived from other diſorders. When it is an original diſeaſe, it generally proceeds from a voraciouſneſs, and a hard diet; whence crude and indigeſted humours will ariſe and prevent digeſtion; which is often known from a ſenſe of weight in the ſtomach, or from copious wind and eructations of various kinds, chiefly the nidorous and acid; or from a nauſea and reaching to vomit. In old perſons, when the whole body is feeble, it may proceed from want of ſpirits, or the fluids being defective, or from a debility of the contractive force and motions of the ſtomach, whence an univerſal decay proceeds.

This diſorder is often a ſymptom of other diſeaſes, particularly the acute, as inflammations, aſthma, dropſy, hypochondriac paſſion, melancholy, the gout, vomiting, or dyſentery; or when the humours are ſo corrupt, and the ſpirits ſo oppreſſed in malignant diſeaſes, that the faculty of digeſtion is depraved, or nature may be ſo buſied in expelling another diſeaſe, as to neglect this. In the laſt caſe it cannot be cured till the diſeaſe itſelf is vanquiſhed.

In the ſpontaneous anorexy, when the ſtomach is loaded with crudities, which cauſe a reaching to vomit, a ſingle emetic will often perform a cure, joined to a ſtomachic remedy: but if there is no reaching, the humours are to be incided and digeſted with bitter ſalts, ſuch as the ſalts of bitter herbs, tartar vitriolated, arcanum duplicatum, or the like, given in powder from a ſcruple to half a dram, ſeveral times in a day; or terra foliata tartari, diſſolved, to ſixty drops or more. After this the cathartic, compoſed of bitter ingredients, or Epſom ſalt, may be given.

When the ſtomach and inteſtines are purged, bitter elixirs and tinctures ſhould be uſed, combined with aromatics, from fifty to ſixty drops, or upwards, to reſtore the tone of the ſtomach. Candied ginger, orange-peel, or elixir vitrioli, eſpecially when the peccant humour is alkalious or bilious, may be properly added to the infuſions of bitter roots and herbs, with aromatics in wine, eſpecially wormwood wine, and the like ſtomachic liquors.

When the crudities of the ſtomach are acid, abſorbents are proper, ſuch as crabs eyes, mother of pearl and coral, and then a ſuitable purge of aloetic pills or rhubarb, or a bitter cathartic ſalt. Magneſia alba is likewiſe uſeful on this account, being abſorbent and uſeful in the hypochondriac paſſion. This ſhould be taken for ſome days, from fifteen to twenty grains; if the doſe be enlarged to a dram or two, it will purge pretty briſkly. The crudities being evacuated, bitters and aromatics are proper, as well as chalybeates and tinctures of ſteel; ſpa waters, and other mineral waters of the ſame kind, together with exerciſe, and now and then a draught of generous wine will be found very advantageous. Smoaking tobacco frequently is hurtful, as well as drinking of drams; the diet ſhould be regular, and the patient muſt avoid aliments that are hard of digeſtion, fat, or flatulent, and alſo intenſe ſtudies.

ANSÆ, in aſtronomy, implies the parts of Saturn's ring projecting beyond the diſk of the planet. See the article SATURN.

The word is Latin, and properly ſignifies handles; theſe parts of the ring appearing like handles to the body of the planet.

ANSER, the gooſe, in natural hiſtory; ſee the article GOOSE.

ANSES, in aſtronomy, the ſame with anſæ. See ANSÆ.

ANT, *Formica*, in natural hiſtory, the name of a well-known inſect, celebrated both for its induſtry and œconomy.

The ſight of ants is really very inſtructive. They are a little people united, like the bees, in a republic governed by its own laws and politics. They have a kind of oblong city, divided into various ſtreets, that terminate at different magazines. Some of the ants conſolidate the earth, and prevent its falling in, by a ſurface of glue with which they incruſt it. Thoſe which we commonly ſee, amaſs ſeveral ſplinters of wood, which they draw over the tops of their ſtreets, and uſe them as rafters to ſuſtain the roof; and acroſs theſe they lay another rank of ſplinters, and cover them with a heap of dry ruſhes, graſs, and ſtraw, which they raiſe with a double ſlope, to turn the current of the water from their magazines; ſome of which are appropriated to receive their proviſions, and in the others they depoſit their eggs, and the worms that proceed from them.

As to their proviſions, they take up with every thing eatable, and are indefatigable in bringing home their ſupplies. You may ſee one loaded with the kernel of ſome fruit, another bends under the weight of a dead gnat. Sometimes ſeveral of them are at work on the carcaſe of a May-fly, or ſome other inſect. What cannot be removed they eat on the ſpot, and carry home all that is capable of being preſerved. The whole ſociety is not permitted to make excurſions at random: ſome are detached, as ſcouts, to get intelligence; and, according to the tidings they bring, all the community are upon the march, either to attack a ripe pear, a cake of ſugar, or a jar of ſweet-meats; and, in order to come to this jar, they leave the garden, and aſcend the houſe; there they find this mine of ſugar, this rich Peru of ſweets, that opens all its treaſures to their view. But their march to it, as well as their return from it, is under ſome regulation: the whole band is ordered to aſſemble and move in the ſame track; but the injunction is not executed with much ſeverity, and they have liberty to expatiate when they have an opportunity of ſpringing any game in the country. The green vermin that make an infinite waſte among flowers, and cockle the leaves of the peach and pear trees, are ſurrounded with a glue, or kind of honey, which is ſought for by the ants with great avidity; but they are not ſollicitous either for the fleſh of theſe creatures, or for any part of the plant. Theſe are the vermin who are the authors of all that deſtruction to our trees, which is falſely imputed to the ants, and draws upon them a very unjuſt and cruel perſecution.

Their next prevailing paſſion is to amaſs a ſtore of proviſions that will keep; and, leſt the humidity of the cells ſhould make the corn ſhoot up, we are told that they gnaw off the buds which grow at the point of the grain. But this ſeems to be a vulgar error; though all the ancients mention it; and Aldrovandus aſſures us he had ſeen it. Their labours, as well as their inclinations, may indeed vary according to their ſpecies. And it is likewiſe probable that their aurelias, which are ſometimes yellow, have been taken for grains of corn without buds, and ſwelled by moiſture.

The ants, after they have paſſed the ſummer in a conſtant employment and fatigue, ſhut themſelves up in the winter, and enjoy the fruits of their labour in peace; however, it is very probable, they eat but little in that ſeaſon, and are either benumbed, or buried in ſleep, like a multitude of other inſects; and therefore their induſtry in ſtoring up proviſions, is not ſo much intended to guard againſt the winter, as to provide, during the harveſt, a neceſſary ſuſtenance for their young. They nouriſh them, as ſoon as they leave the egg, with an aſſiduity that employs the whole nation; and the care of their little progeny is eſteemed a matter of importance to all the ſtate.

When the young quit the egg, they are little worms, no longer than common grains of ſand, and after they have for ſome time received their aliment, which is brought to them in common, and diſtributed in equal proportions, they ſpin a thread, and wrap themſelves up in a white web, and ſometimes in one that is yellow; at which period they ceaſe to eat, and become aurelias. In this ſtate, ſome people fancy they are the eggs of ants, when in reality they are the nymphs, out of whoſe ruins the new piſmires are to riſe. Though the young diſcontinue their eating, their nurture ſtill proves very fatiguing to their parents. Theſe have generally ſeveral apartments, and remove their young from the nurſery to ſome other manſion they intend to people. They either raiſe the aurelias toward the ſurface of the earth, or ſink them to a diſtance from it, in proportion as the ſeaſon is either warm or cold, rainy or dry. They raiſe them when the weather proves ſerene, or when a long drought is ſucceeded by gentle dews; but, at the approach of night and cold, or the appearance of ſhowers, they claſp their beloved charge in their arms, and deſcend with them to ſuch a depth, that one muſt then dig above a foot into the earth before thoſe aurelias can be diſcovered.

If a mouſe, frog, or other like animal be placed in an ant-hill, he will be devoured, in a few days, to the bones and ligaments. Hence we are furniſhed with a method of obtaining ſkeletons of thoſe animals, exquiſitely beautiful and perfect, far ſurpaſſing any thing that can be executed by artificial anatomy. The ſubject is for this purpoſe to be incloſed in a wooden box, and properly diſtended, to prevent the parts from collapſing or being cruſhed together by the earth. The box is to be perforated with a number of holes, through which the inſects will preſently find their way.

Ant-Eater, in natural hiſtory, the name of an American quadruped that lives upon ants.

This creature is as long and as tall as a middle ſized dog; his hind legs reſemble thoſe of the bear; but his fore legs are more ſlender. His fore feet are flat, and divided into four toes, armed with long claws; but thoſe behind have five toes. His head is long, with a ſharp prominent ſnout, ſmall round black eyes. and very black ears. Thoſe that have meaſured the tongue affirm, that they have found it upwards of two feet in length, but very ſlender: he is obliged to bend part of it back when he keeps it within his mouth, the jaws being too ſhort to contain it without this artifice.

He lives upon ants, as was obſerved above, and when he has found out one of their neſts, he opens the upper part of it with his claws, that he may have room to put in his ſnout and tongue. This is beſmeared with a ſlimy liquor, and is ſoon covered with ants, when he draws it into his mouth and ſwallows them. He repeats this practice as long as they will run into the ſame ſnare.

The tail of this creature is very remarkable, and in ſome meaſure reſembles that of the fox. It is generally two feet in length, almoſt flat, and covered on all ſides with hair, from fifteen to twenty inches long: it is a little harſh, which gives it ſomewhat the appearance of a horſe's tail; is very ſtrong, and he can move it juſt as he pleaſes; when he turns it upon his back, it entirely covers it, and defends the creature from the rain, which he greatly diſlikes.

Ant-Bear, the ſame with ant-eater deſcribed in the preceding article.

Ant-Hills, in huſbandry, are little hillocks of earth which the ants throw up for their habitation for the breeding their young. They are a very great miſchief to dry paſtures, not only by waſting ſo much land as they cover, but by hindering the ſcythe in mowing the graſs, and yielding a poor hungry food pernicious to cattle.

The manner of deſtroying them is to cut them into four parts from the top, and then dig into them ſo deep as to take out the core below, ſo deep that, when the turf is laid down again, it may lie ſomewhat lower than the level of the reſt of the land; and this will prevent the ants from returning to the ſame place, which otherwiſe they would certainly do. The earth that is taken out muſt be ſcattered to as great a diſtance as may be, otherwiſe they will collect it together, and make another hill juſt by.

The proper time for doing this is winter, and, if the places be left open, the froſts and rains of that time of the year will deſtroy the reſt; but in this caſe care muſt be taken that they are covered up early enough in the ſpring, otherwiſe they will be leſs fertile in graſs than the other places.

In Hertfordſhire they uſe a particular kind of ſpade to this purpoſe. It is very ſharp, and formed at the top into the ſhape of a creſcent; ſo that the whole edge makes up more than three fourths of a circle: this cuts in every part, and does the buſineſs very quickly and effectually: others uſe the ſame inſtruments that they do for mole-hills.

Human dung is a better remedy than all theſe, as is proved by experiment; for it will kill great numbers of them, and drive all the reſt away, if only a ſmall quantity of it be put into their hills.

ANTA, in ancient architecture, a ſquare pilaſter, placed at the corners of the buildings.—Le Clerc uſes the term to ſignify a kind of ſhaft of a pillar, without baſe or capital, and even without any moulding.

Anta, in natural hiſtory, the name of an animal common in Brazil, and called tapierete.

It is as large as a calf, but reſembles a hog in ſhape, eſpecially the head, which terminates in a point on the upper part. It has a proboſcis over the mouth, which it can contract or extend at pleaſure. The eyes are ſmall, and like thoſe of a hog, but thicker. The fore feet have four toes, three of which are large, and the other ſmall; but the hind feet only three. It has no tail; and the ſkin is hard: and, while the animal is young, it is covered with ſhort hair of a darkiſh colour, variegated with white ſpots; but when it has done growing, the colour is yellow, and without ſpots. It feeds chiefly in the night, on graſs, ſugar canes, cabbages, and the like. The fleſh has a taſte like beef, but not very agreeable.

The Indians make a ſort of helmets of their ſkins, which cannot be penetrated with an arrow.

ANTAGONIST *Muſcles*, in anatomy, are thoſe which have oppoſite functions, as flexors and extenſors; abductors and adductors, &c.

ANTARCTIC, ſomething oppoſite to the Bear, a conſtellation near the north pole.

The word is formed from the Greek, *αντι*, againſt, or oppoſite, and *αρκτος*, a bear.

Antarctic *Circle*, in geography and aſtronomy, is a ſmall circle of the ſphere, 23°. 30′. diſtant from the ſouth pole.

Antarctic *Pole*, the ſame with ſouth pole. See Sphere.

ANTARES, in aſtronomy, the name of a ſtar of the firſt magnitude, called alſo the ſcorpion's heart. Its longitude is 6°. 13′, 14″. of Sagittarius; and its latitude 4°. 31′. 26″. S.

ANTE, in heraldry, implies the pieces being let into one another, in the form expreſſed in blazoning; as by dove-tails, rounds, ſwallow-tails, or the like.

ANTECEDENT, in a general ſenſe, implies ſomething that goes before another, either with regard to time or place.

The word is Latin, *antecedens*, and compounded of *ante*, before, and *cedo*, to go.

ANTECEDENT, in grammar, is the word to which the relative refers. Thus in the ſentence, "The book that "we read," the word book is the antecedent.

ANTECEDENT, in logic, is the firſt propoſition of an enthymema. See the article ENTHYMEMA.

ANTECEDENT, in mathematics, is the firſt of two terms in a ratio, being that which is compared to the other. Thus in the ratio of x to y, x is the antecedent. See RATIO.

ANTECEDENT *Decree*, in the ſchool philoſophy, is a decree preceding ſome other decree. It is a famous diſpute whether predeſtination be a decree antecedent, or ſubſequent to faith.

ANTECEDENT *Signs*, among phyſicians, ſuch as are obſerved before a diſtemper is formed ſufficiently to be reduced to any particular claſs. Thus a bad diſpoſition of the blood is an antecedent ſign, becauſe it precedes an infinite number of diſeaſes.

ANTECEDENCE, *Antecedentia*, in aſtronomy, implies an apparent motion towards the weſt, or contrary to the order of the ſigns.

ANTECHAMBER, in architecture, implies the chamber that leads to the chief apartment.

The word is compounded of the Latin prepoſition, *ante*, before, and *chamber*.

ANTEDATE, in law, implies a ſpurious or falſe date, prior to the true date of any writing.

The word is compounded of the Latin, *ante*, before, and *datum*, a date.

ANTEDILUVIAN, in a general ſenſe, implies ſomething that exiſted before the deluge.

The word is Latin, and compounded of *ante*, before, and *diluvium*, a deluge.

ANTEDILUVIAN *Philoſophy*, the philoſophy of the patriarchs before the deluge.

Some who have traced philoſophy back to its origin, are ſo far from ſtopping at the firſt man, that they ſoar to the ſkies, and ſeek it among the angels. But was Adam, the firſt man, really a philoſopher? This ſeveral make no doubt of. Hornius, in ſhort, tells us that, in his opinion, Adam, before his fall, was not only perfect in all knowledge, but alſo retained ſome veſtigia or traces of this perfection after his fall. The remembrance of what he had loſt being always in his mind, kindled in his heart a paſſionate deſire of recovering the knowledge ſin had robbed him of, and diſſipating the darkneſs which had thrown a veil over it. To ſatisfy this thirſt of knowledge, he dedicated his whole life to the contemplation of nature; and, carrying ſcience to the higheſt pitch, left moſt of his diſcoveries to his children, becauſe he lived long enough to communicate them. Such are the reaſonings of Dr. Hornius; to which we might add what the Jewiſh rabbins have wrote, if their fables merited our attention. But Hornius offers ſome further arguments to prove Adam a philoſopher, and even of the firſt rank. Had he not been a naturaliſt, ſays Hornius, could he have given the animals names ſo expreſſive of their nature? Euſebius has brought a proof of Adam's logic. As to the mathematics, he muſt have certainly underſtood them, or he could never have made cloaths out of the ſkins of wild beaſts, have built him an houſe, obſerved the motions of the ſtars, and regulated the year by the courſe of the ſun. But the higheſt of all theſe convincing arguments, brought in favour of Adam's philoſophy, is this, that he wrote books, that theſe books contained all the ſublime ſciences which he had made himſelf maſter of with incredible labour. It is true, indeed, theſe books are apocryphal, or loſt; but that ſignifies nothing; becauſe tradition has preſerved the titles of the authentic books whereof he was the real author.

Nothing is more eaſy than to refute all theſe arguments: firſt, if we ſpeak of Adam's wiſdom before the fall, it has no relation to philoſophy in the ſenſe we accept it, for that wiſdom conſiſted in the knowledge of God and himſelf; but particularly in that practical knowledge which might lead him to the happineſs for which he was created. It is true, Adam poſſeſſed this kind of wiſdom; but what connection has this with a philoſophy which Admiration and Curioſity, the daughters of Ignorance, produce, which is not acquired without the conflict of different opinions? The wiſdom with which Adam was created, was that divine wiſdom which is the fruit of grace, which God pours forth even on the weakeſt minds. This is, no doubt, a true philoſophy which the rational mind firſt conceived, and all ages have concurred to produce and carry to its preſent maturity. If Adam, in his ſtate of innocence, had no philoſophy, what will become of that they attribute to him after his fall, which was but a faint glimmering of what he had before? Would they perſuade us that Adam, whoſe ſin continually followed him, and who could think on nothing but the means of reconciling himſelf to God, and reſiſting the evils that ſurround him, had a mind ſufficiently at eaſe to apply himſelf to the barren ſpeculations of vain philoſophy? He gave names to animals; but does this prove him well acquainted with their nature and properties? He reaſoned with Eve, our common mother, and his children; from thence ſhall we conclude he underſtood the art of logic? By ſuch reaſoning as this we may make every man a logician. He built himſelf a poor cottage, governed his family prudently, inſtructed them in their duty, taught them religious worſhip; but are theſe ſufficient reaſons to prove Adam an architect, a politician, and divine? How can any one maintain Adam to have been the firſt inventor of letters, when it is evident that mankind, long after the flood, made uſe of hieroglyphics, the moſt imperfect of all kinds of writing, to convey their ideas to each other; and that this was the firſt attempt made of the kind. The wonders of nature are expoſed to our view in the moſt glaring light a long time before we have reaſon, opportunity, or penetration enough to enquire into them. If we came into the world with the ſame degree of reaſon with which we go to a play-houſe the firſt time, ſtruck, on the ſudden drawing of the curtain, with the magnificence of the ſcenes and decorations of the play, we could not forbear admiring its beauty, and examining its ſtructure; but who is ſurpriſed at what he has ſeen for a courſe of fifty years? Among men, the wants of ſome take up all their time to ſupply their neceſſities; they have none to apply themſelves to metaphyſical ſpeculations; the riſing ſun calls them to their labour; and the fineſt night that ever ſhone on the beſpangled ſky ſpeaks no language to them, or only ſays this, "Go, weary labourer, to reſt." Many of more leiſure either have not had an opportunity to interrogate nature, or wanted capacity to underſtand her anſwers. The philoſophical genius, whoſe ſagacity, ſhaking off the yoke of cuſtom, firſt gazed with admiration on the prodigies of nature which ſurrounded him, deſcended into himſelf, aſked himſelf queſtions, and gave himſelf anſwers concerning all the objects which he ſaw, muſt have been a long time in ſuſpence, might even have died without having credited his own opinions, ſays the author of the Eſſay on Merit and Virtue.

If Adam had no philoſophy, there certainly can be no inconſiſtence in denying it to his children Cain and Seth. Nor are we to imagine that either Jubal or Tubal-Cain were great philoſophers, merely becauſe the one invented muſic, and the other found out the ſecret of working in iron and braſs: perhaps they only improved what others diſcovered before them. But, ſuppoſing them to have been the inventors of theſe arts, does it follow as a neceſſary concluſion they muſt have been philoſophers? Every one knows that many of the arts, moſt uſeful to ſociety, owe their invention to chance; it is the part of philoſophy to reaſon on the genius ſhe diſcovers in them after they are found out. It is a bleſſing chance has prevented our wants, and left philoſophy almoſt nothing to do. Thus you ſee there is no philoſophy either in the branch of Cain or Seth. We find honeſt laborious men before the flood, who applied themſelves to agriculture, preſerved their primitive traditions, tended their flocks, and retained a true knowledge of God; but were no philoſophers: wherefore it is in vain to ſeek the origin and riſe of philoſophy in the time preceding the flood.

ANTEDILUVIAN *World*, the earth as it exiſted before the deluge.

Dr. Burnet and Dr. Woodward differ very widely about the antediluvian world; the former imagines its face and appearance to have been ſmooth, equable, and in all reſpects different from what we now find it to be.

The latter, on the contrary, endeavours to prove that the face of the terraqueous globe, before the deluge, was the ſame as it is now, viz. unequal, diſtinguiſhed into mountains and dales; and having, likewiſe, a ſea, lakes, and rivers; that this ſea was ſalt, as ours is; was ſubject to tides, and poſſeſſed nearly the ſame ſpace and extent that it now does; and that the antediluvian world was ſtocked with animals, vegetables, metals, minerals, &c. that it had the ſame poſition, in reſpect of the ſun, which ours now hath, its axis not being parallel, but inclined, as at preſent, to the place of the ecliptic; conſequently, that there were then the ſame ſucceſſion of weather, and the ſame viciſſitudes of ſeaſons, as now. Mr. Whiſton imagines that the chaos, of which our earth was formed, had been the atmoſphere of a comet; that the annual motion of the earth began as ſoon as it aſſumed a new form; but that the diurnal motion did not take place till the fall of Adam; that before the deluge, the year began at the autumnal equinox; that the orbit of the earth was a perfect circle; and that the ſolar and lunar years were the ſame, each conſiſting of juſt three hundred and ſixty days. The ſtate of the antediluvian philoſophy has likewiſe been the ſubject of much debate among authors.

ANTELOPE, in natural hiſtory, the name of an animal called, by Latin authors, *gazella Africana*, and thought by ſome to be the ſame as the Lybian goat.

The antelope is very ſwift; has a white belly, and the reſt of the body of a fallow colour; the white and the fallow on the ſides are parted by a black ſtripe; the eyes are black, the ears large, the tail blackiſh, and a ſtripe a little more brown than the reſt of the hair deſcends from the eye down to the muzzle. He is about the ſize of a roe-buck, and his hair very ſhort. Under the hair the ſkin is black and ſhining, though in ſome it is greyiſh. The ears are large and bald within, where the ſkin is black, like poliſhed ebony. The eyes are black and large; and the horns are likewiſe black, ſtriped croſsways. They are about fifteen inches long, and near an inch in diameter at the bottom. They are ſharp at the points, and pretty ſtraight, though they turn a little outwards in ſome places, and in others inwards. The horns of the male are bent a little more back than thoſe of the female, which are very round; but thoſe of the male are a little flattiſh.

Theſe horns at the root have a tuft of hair longer than that on the reſt of the body, and are hollow about half way, in which is a pointed bone that faſtens them to the ſkull by help of the ſkin that covers them. This ſkin is very hard, thick, and full of blood veſſels.

The noſe is a little flat, like that of a goat, but more in the males than the females. The palate is covered with a hard ſkin in the form of long ſcales, and there are no fore teeth in the upper jaw, it being a ruminating animal. The tail of the females is covered with long blackiſh hair; but in the males it is but little longer than on the reſt of the body, and yet it is more ſoft than the former. The fore legs, about the part called the knee, are furniſhed with pretty long coarſe hair; and here likewiſe the ſkin is thicker than in other parts, and ſeems to ſerve inſtead of a cuſhion to kneel down upon, like the calloſity in the knee of a camel. The feet of the antelope are more cloven than in moſt other animals, and covered with hoofs of a horny ſubſtance, forming the two points of the toes, that are tied together by a ſkin which will ſtretch greatly. The female antelope has but two udders and two teats, and on each ſide the udders in the groin are deep cavities, where the ſkin is without hair, like the teats. Theſe cavities diſcharge an unctuous matter, which has given occaſion for ſome to miſtake the antelope for the civet cat, but very abſurdly, for they are quite different animals.

ANTENNÆ, in natural hiſtory, ſlender bodies, with which nature hath furniſhed the heads of inſects, being the ſame with what are called in Engliſh the horns or feelers.

ANTEPENULTIMA, in grammar, the third ſyllable of a word from the end, or the laſt ſyllable but two.

ANTEPREDICAMENTS, in logic, certain preliminary queſtions tending to illuſtrate the doctrine of predicaments and categories. See PREDICAMENTS.

ANTEVIRGILIAN *Huſbandry*. See HUSBANDRY.

ANTHELIX, in anatomy, the inward protuberance of the external ear. See EAR.

ANTHELMINTICS, among phyſicians, medicines proper to deſtroy worms. See WORMS.

ANTHEM, a church ſong, conſiſting of ſome paſſages of ſcripture ſet to muſic, and adapted to ſome ſolemnity.

ANTHERÆ, in botany, the ſmall roundiſh or oblong bodies on the tops of the ſtamina of plants. See STAMINA.

ANTHOLOGY, a diſcourſe on flowers; or a collection of beautiful paſſages from famous authors.

The word is compounded of the Greek, ανθος, a flower, and λογος, a diſcourſe.

ANTHOLOGY is alſo a name given to a collection of Greek epigrams.

ANTHONY, or *Knights of St.* ANTHONY, a military order inſtituted by Albert, duke of Bavaria, Holland, and Zealand, when he meditated a war againſt the Turks in 1382. The knights wore a collar of gold, made in the form of a hermit's girdle, from which hung a ſtick, cut in the form of a crutch; as repreſented in the pictures of St. Anthony.

St. ANTHONY'*s Fire*, a name ſometimes given to the eryſipelas. See ERYSIPELAS.

ANTHOPHYLLI, a name given to the larger ſpecies of cloves. See CLOVES.

ANTHORA, yellow helmet flower, counterpoiſon monks-hood, or wholeſome wolfsbane, in botany, the name of a plant with divided leaves, and naked flowers, conſiſting of five petals, the uppermoſt of which is ſhaped like a hood; each flower is followed by three or more pods, containing wrinkled angular ſeeds. It is diſtinguiſhed from the other aconites or wolfsbanes, by the leaves not being gloſſy, by their being cut quite down to the pedicle, and by the ſegments being very narrow, and of nearly the ſame width from end to end.

This plant is a native of the Alps and Pyrennees, from whence the dried roots are ſometimes brought to us. They are generally of an irregular roundiſh ſhape, ſometimes a little oblong, of a brown colour on the outſide, and white within, hard to break, but not tough.

ANTHOS, a Greek word, properly ſignifying a flower; but uſed by way of eminence for roſemary. See ROSEMARY.

ANTHRAX, a name by which the ancients called a gem known at preſent by the name of carbuncle. See CARBUNCLE.

ANTHROPOGRAPHY, the deſcription of the human body, its parts, ſtructure, &c.

The word is formed from the Greek, ανθρωπος, a man, and γραφω, to deſcribe.

ANTHROPOMORPHITES, a ſect of heretics, ſo denominated from ανθρωπος, man, and μορφη, ſhape; for they, through great ſimplicity, taking every thing ſpoken in ſcripture of God in a literal ſenſe, particularly that paſſage in Geneſis, in which it is ſaid, that God made man after his own image, imagined him to be in the ſhape of a man, having real hands, feet, &c.

ANTHROPOPHAGY, the act of eating human fleſh.

The word is formed from the Greek, ανθρωπος, a man, and φαγω, to eat.

ANTHYPOPHORA, in rhetoric, the ſame with hypophora. See HYPOPHORA.

ANTICARDIUM, in botany; ſee the article SCROBICULUM.

ANTICHRIST, among eccleſiaſtical writers, implies a great adverſary of Chriſtianity, who is to appear upon the earth before the end of the world.

ANTICOR, in farriery, implies an inflammation of a horſe's throat, being the ſame with the quinzy in the human ſpecies.

ANTIDOTE, among phyſicians, implies a remedy againſt peſtilential diſeaſes.

It alſo ſignifies a medicine which prevents the ill effects of poiſon.

ANTIENT, or ANCIENT, a term applied to things that exiſted long ago.

Antient, in a military ſenſe, implies the enſign or colours.

Antient, in naval affairs, ſignifies the flag carried at the ſtern of a ſhip.

ANTILOGARITHM. See the article Logarithm.

ANTILOGY, in literature, denotes an inconſiſtency between two or more paſſages of the ſame book.

ANTIMONARCHICAL, a name given to whatever oppoſes monarchical government.

ANTIMONY, in natural hiſtory, a blackiſh mineral ſubſtance, ſtaining the hands, full of long, ſhining, needle-like ſtriæ, hard, brittle, and conſiderably heavy.

It is found in different parts of Europe, as Bohemia, Saxony, Tranſylvania, Hungary, and France, commonly in mines by itſelf, intermixed with earthy or ſtony matters. Sometimes it is blended with the richer ores of ſilver, and renders the extraction of that metal difficult; antimony volatilizing a part of the ſilver, or, in the language of the miners, robbing the ore. Antimony is ſeparated from its natural impurities by fuſion in an earthen pot, whoſe bottom is perforated with a number of holes; the fluid antimony paſſing through, whilſt the unfuſible matters remain behind. The melting veſſel is let into another pot ſunk in the ground, and which ſerves as a receiver: this laſt is of a conical figure, and ſuch accordingly is the ſhape of the loaves of antimony met with in the ſhops. The juncture of the two veſſels is cloſely luted; the uppermoſt one covered, and a fire made round it; and ſeveral ſets of this apparatus worked at once. In ſome places, inſtead of a pot with a perforated bottom, one is taken which has no bottom, and a perforated iron-plate placed betwixt it and the receiver; but the other method is to be preferred, as antimony in fuſion is apt to diſſolve a part of the iron.

Antimony has been by many eſteemed a poiſon. In 1566, its uſe was prohibited in France by an edict of parliament; and in 1609, one Beſnier was expelled from the faculty for having given it. The edict was repealed in 1650; antimony having a few years before been received into the number of purgatives. In 1668, a new edict came forth, prohibiting its being uſed by any one but the doctors of the faculty. Others again have been extravagantly fond of it, and aſcribed to it extraordinary virtues, as Alexander Van Schuten, Glauber, and Faber: Baſil Valentine ranks it among the wonders of the world, and places it in a triumphal car. Thus much is certain, that antimony, in its crude ſtate, is not a poiſon, but a medicine of great efficacy; an excellent reſolvent and purifier of the juices, if given from four grains to half a dram, along with abſorbents: that it is capable of being rendered, by various operations and additions, either truly poiſonous, or more medicinal than in its crude ſtate: that its moſt virulent preparations may, by ſlight managements, be made ſalutary; and its moſt ſalutary ones virulent.

Antimony is not a pure ſemimetal, but a ſulphurated ſemimetal. Thrown into the fire, it burns with a blue flame and ſulphureous vapours: on digeſting powdered antimony in aqua regia, the metallic part is diſſolved, and the ſulphur left. The ſulphur of antimony, purified from the metallic part, is perfectly the ſame with the common brimſtone of the ſhops, poſſeſſing the ſame properties, and anſwering the ſame uſes: if the ſemimetal, freed from the ſulphur naturally mixed with it, be afterwards melted with common brimſtone, it reſumes the appearance and qualities of crude antimony. Many have imagined, that this mineral, beſides common ſulphur, contains a golden or ſolar ſulphur; becauſe antimony purifies and heightens the colour of gold, and becauſe it diſſolves, as gold does, in aqua regia. But, with regard to the ſolubility in aqua regia, it is not the ſulphureous, but the metallic matter of the antimony that diſſolves: if nothing beſides gold and antimony were acted upon by that menſtruum, there might be ſome plauſibility in the argument; but ſurely, when ſo many ſubſtances diſſolve in it, as iron, copper, lead, tin, quickſilver, zinc, various earths, &c. ſolubility in aqua regia can be no proof of a ſolar impregnation. In the purification of gold, the ſulphur of antimony has no other effect than common brimſtone would equally produce: when gold, containing an admixture of other metals, is melted with antimony, the ſulphur, having little affinity with its own ſemimetal, forſakes it, and unites with the ſilver, copper, or other metalic bodies mixed with the gold, but has no action on the gold itſelf: thus only the impurities of the gold are combined with the ſulphur of the antimony into a ſcoria, which flows on the ſurface; whilſt the gold and the ſemimetal of the antimony form one compound at the bottom: if this compound be expoſed to a ſtrong fire, and a free draught or blaſt of air, it evaporates in fumes, and leaves the gold pure behind it. This proceſs ſhews the reſiſtance of gold to ſulphur, and to the volatilizing power of the antimonial ſemimetal, but ſurely gives no foundation for imagining a ſolar ſulphur to exiſt in antimony.—As gold is the only metal (platina excepted) that totally reſiſts antimony or its ſulphur, this mineral has been called by the chemiſts *balneum ſolius ſolis*, *balneum regis*, *lupus*, *ultimus judex*, *&c.*

The ſeparation of metallic bodies from ſulphur, by fuſion, is no other than a ſpecies of precipitation; and accordingly it is called by ſome dry precipitation; as it depends upon the addition of ſome third ſubſtance, whether metallic or not, to which the ſulphur has a greater affinity than to that metal which it is already combined with: in conſequence of this affinity, the ſulphur in fuſion lets go its metal to unite with the ſubſtance ſuperadded, and forms with this a light ſcoria, from which the other ſubſides by its own gravity. This is the foundation of all the dry partings of metals: metallic bodies, ſeparated by this dry precipitation, are commonly called reguli, eſpecially when brittle. The metallic part of antimony, in particular, is diſtinguiſhed by no other name than that of regulus of antimony.

The proportion of regulus and ſulphur in crude antimony, it is difficult and ſcarce poſſible to exactly determine; as there is always ſome loſs in purifying either the ſulphur from the regulus, or the regulus from the ſulphur. There is reaſon to believe that the regulus amounts to one half the quantity of the compound, and rather more than leſs.

The regulus of antimony by precipitation is obtained by melting the antimony with fixed alkaline ſalts, iron, copper, tin, &c. the ſulphur having a greater affinity with theſe than with the regulus, and forſaking the latter to unite with the former. The regulus prepared with alkalies is called ſimple; that with metallic bodies is diſtinguiſhed by the name of the particular metal, martial, venereal, jovial, &c. All theſe methods are attended with ſome inconveniencies. Alkaline ſalts effectually abſorb the ſulphur; but they form with it a *hepar ſulphuris*, which in fuſion diſſolves all the metals: hence, in proportion as the regulus is freed from its ſulphur by the alkali, a part of it is taken up again by the compound which the ſulphur forms with the alkali: one third, one half, and often three fourths of the regulus are thus rediſſolved; and often we find very little regulus left. Metallic additions are free from this inconvenience, and conſequently occaſion the yield of regulus to be much larger: but the regulus thus obtained is never entirely free from ſome portion of the matter ſuperadded. Some have endeavoured to promote the ſeparation of the regulus by inflammable additions, as powdered charcoal, pitch, reſin, &c. but theſe do not at all mend the matter. Antimony, treated with inflammable ſubſtances alone, yields no regulus; and if alkaline ſalts alſo are taken, the inconveniencies will ſtill be the ſame as when thoſe ſalts are uſed by themſelves. Many have ſubſtituted to alkaline ſalts crude tartar, or a mixture of tartar and nitre, and thought that then they employed no alkalies; not aware that thoſe are the very ſalts from which alkalies are produced for chemical uſes by the action of fire; and that they do not here effect the intended ſeparation, till the heat has reduced them to that ſtate. There are however ſome differences obſerved in the quantity of regulus according to the different additions.

Kunckel has given a method of preparing regulus of antimony by calcination. He calcines the antimony till it ceaſes to emit any ſulphureous ſmell with care, to prevent its running into lumps; then mixes the calx with oil or fat, and a little powdered charcoal, puts the mixture into a crucible to melt, and, as ſoon as the regulus begins to ſhew itſelf, injects by degrees ſome powdered nitre in the proportion of an ounce to a pound of antimony: the matter in thin fuſion being poured out, a pure regulus is obtained, in much greater quantity than by the foregoing methods. There is another, but more expenſive, way of procuring a large yield of pure regulus; namely, by extracting the regulus from the antimony by acid menſtrua, as aqua regis, or ſpirit of ſalt, precipitating it from this ſolution; and afterwards reviving the precipitate, by melting it with inflammable additions.

Pure regulus of antimony, by whatever means obtained, is a bright ſemimetal, reſembling tin or duſky ſilver; without any thing of the bluiſh caſt of zinc, or the yellowiſh one of biſmuth. It is one of the lighteſt of the metallic bodies, (about ſeven times ſpecifically heavier than water, moderately hard, entirely brittle, and of a ſparkling plated texture. In a fire not very ſtrong, it ſmokes copiouſly, and by degrees totally evaporates: by a gentler fire, continued for ſome time, it is changed into a whitiſh calx; which, on raiſing the heat, melts into a yellowiſh or reddiſh glaſs. Melted with ſilver, or the malleable metals, it renders them hard and brittle. It deſtroys the magnetic power of iron, which other metallic bodies only weaken in proportion to their quantity. It does not amalgamate, or not without great difficulty, with mercury: if a mixture of it with ſilver and copper be reduced into fine powder, even thoſe metals will not, in that ſtate, be acted upon by mercury. In the human body it acts as a virulent emetic and cathartic; and impregnates vegetable acids, as vinegar and acid wines, with thoſe virtues, almoſt inexhauſtibly. By ſulphur, and by calcination with nitre, its malignity is abated, and its emetic power changed into a diaphoretic one. As ſoon as it is reſtored to its pure metallic ſtate, it reſumes its virulence; which may be again deſtroyed, and again reſtored, and almoſt infinitely varied.

Hoffman has given an account of the different medicinal effects of antimony, as depending on its different treatments. He obſerves, that crude antimony, on account of the regulus being corrected by the ſulphur, is not only ſafe, but in many caſes a medicine of great ſervice, both for man and other animals. That by ſimple fuſion it acquires a degree of malignity; but a far greater if melted with half its weight of nitre, which conſumes nearly all the ſulphur, and leaves the regulus bare. That antimony, or its regulus, mixed with common ſalt, calcined over a gentle fire for ſeveral hours, and kept continually ſtirring, and afterwards edulcorated with water, yields an aſh-grey calx, which is ſo fixed as to bear a melting heat, and proves a mild and ſafe diaphoretic, void of any malignant or emetic quality. That antimony, by calcination with a gentle fire in an earthen veſſel, in the open air, changes into a calx, which melts with difficulty, and which has no malignity. That if this calx be melted with a ſtrong fire into glaſs, it becomes ſo active, that a few grains will occaſion a violent vomiting and purging, or even mortal convulſions and inflammations. That the powdered regulus, calcined in a glaſs-vial, placed in ſand for ſeveral days, becomes a greyiſh diaphoretic powder; which reduced into regulus by fuſion with powdered charcoal, nitre, and a little fat, proves again virulent. That when antimony is melted with one fourth its weight of ſalted tartar, the whole poured into a mould, the ſcoria ſeparated, and the more ponderous matter pulverized; the reddiſh powder thus obtained, is ſalutary: but that when antimony is melted with three or four times its weight of ſalt of tartar, both the ſcoriæ and the regulus are virulent. That equal parts of antimony and nitre, melted together, yield a virulent maſs; but one part of antimony, with two or three of nitre, is an uſeful diaphoretic. That on melting the diaphoretic calces with fat, charcoal powder and nitre, the virulent regulus is revived. And thus one preparation may be changed into another, a ſalutary into a poiſonous, and a poiſonous into a ſalutary one.

Preparations of ANTIMONY.—The preparations of antimony are extremely numerous. Lemery, in his Treatiſe on Antimony, deſcribes no leſs than two hundred; among which there are many good, and many uſeleſs ones. That gentleman was an excellent chemiſt, but an unhappy philoſopher: we may depend on his operations, but we ſhould diſtruſt his theory. With regard to the antimonials, the greater number even of the common preparations are unneceſſary; many of them differing little from one another, and all of them being either emetic or diaphoretic. The preparations of antimony may be ranged, according to the general operations by which they are produced, under four heads; thoſe obtained by ſolution, by diſtillation, by ſublimation, and by calcination.

Golden Sulphur of ANTIMONY.—If powdered antimony be boiled in alkaline lixivia, or ſope leys; the ſulphur, and, by the mediation of the ſulphur, a part of the regulus, will be diſſolved into a yellowiſh red liquor. Any acid added to this ſolution precipitates what the alkaline liquor had taken up, in form of a yellowiſh or reddiſh powder, called ſulphur, or golden ſulphur of antimony; the powder which ſettles firſt is groſſer and darker coloured than thoſe which follow; it appears of a deep reddiſh brown, whilſt that which ſubſides laſt is of a pale yellow. The firſt is alſo the moſt active.

There are ſundry variations of this proceſs, both in regard to the ſolution and the precipitation.. A difference in the manner of preparing the ſolution does not ſeem to affect the virtue of the medicine; but a difference in the acid uſed for the precipitation does; different acids having very different effects upon antimony: thus, whilſt the marine renders it either corroſive, or emetic, the addition of the nitrous deſtroys the virulence of both preparations, and renders the antimony mildly diaphoretic.

All the antimonial ſulphurs are emetic and cathartic: thoſe which precipitate firſt are much more ſtrongly ſo than the powder which falls laſt; the laſt precipitates, if they prove emetic once or twice, ceaſe to have that effect upon continuing their uſe, and act chiefly as diaphoretics; and hence are greatly to be preferred to the firſt.—A powder is vended by the Carthuſian friars in Paris, at a conſiderable price, as a ſpecific againſt ſundry diſorders; commonly called poudre des chartreux, but by themſelves kermes mineral. See KERMES *Mineral.*

Butter of ANTIMONY.—For diſſolving the regulus of antimony without the ſulphur, the moſt concentrated ſpirit of ſalt, or aqua regis, is neceſſary. For obtaining the ſolution in ſpirit of ſalt, mercury ſublimate and powdered antimony are mixed together, and digeſted in a glaſs-retort placed in ſand: the marine acid in the ſublimate forſakes the mercury, and corrodes or diſſolves the antimonial regulus; whilſt the mercury of the ſublimate unites with the antimonial ſulphur. But the ſolution of the regulus, thus effected, cannot be commodiouſly ſeparated from the other matter but by diſtillation: on increaſing the fire, the regulus ariſes, diſſolved in the concentrated acid not in a liquid form, but in that of a thick unctuous ſubſtance, like butter; hence called butter of antimony. The butter liquefies by heat; and requires the cautious application of a live coal to melt it down from the neck of the retort. By rectification or expoſure to the air, it becomes fluid, but ſtill retains the name of butter. The addition of water, either in its thick or fluid ſtate, by diluting the acid, precipitates the regulus diſſolved in it. The proportions of ſublimate and antimony commonly employed, are three parts of the former to one of the latter.

Flowers of ANTIMONY.—Theſe are prepared by ſubliming either the crude antimony, or the regulus, with a number of aludels; the fire being kept up ſtrong, and a blaſt of air impelled occaſionally by a pair of bellows upon the matter in the ſubliming pot, to promote its evaporation. The antimonial flowers are in general of great activity, and though recommended by ſome as arcana in particular diſorders, require to be uſed with great caution.

Cinnabar of ANTIMONY.—After the diſtillation of butter of antimony, the mercury and the ſulphur, contained in the ingredients made uſe of for that proceſs, remain behind in the retort. This compound appears of a black colour; urged with a ſtronger fire than that which elevated the butter, it ſublimes into a red maſs, called cinnabar of antimony. This cinnabar has been by many preferred to the common factitious cinnabar, but on no juſt foundation: they both conſiſt of mercury combined with ſulphur; and the only difference betwixt them is, that the antimonial cinnabar contains ſomewhat more ſulphur than the other, and hence appears of a darker colour.

Glaſs of ANTIMONY.—This is chiefly prepared by ſome particular perſons at Amſterdam and Rouen, who have furnaces contrived on purpoſe for calcining large quantities of antimony with little expence of fuel. The glaſs may be eaſily made, by urging the calx in a crucible with a ſtrong fire, and throwing in, towards the end, a little crude antimony or ſulphur. When the vitrefication is completed, the glaſs is poured on a copper plate, or on a flat ſtone. The glaſs of antimony is uſed only for making other emetic preparations, as the emetic wine, &c.

Hepar ANTIMONII, liver of antimony.—Equal parts of crude antimony and nitre mixed together, ſet on fire and ſuffered to deflagrate in an iron mortar, which may be covered with a perforated plate, or injected by degrees into an ignited crucible, yield a liver-coloured maſs, called hepar antimonii, which pulverized and edulcorated with water is named crocus metallorum. Two, three, or even one grain of either of theſe preparations occaſion violent anxieties and vomitings; though a dog will bear a dram, and a horſe a whole ounce, without being apparently any otherwiſe affected than in having the alvine diſcharge increaſed. The emetic wine, emetic tartar, and other medicines made from the glaſs, may alſo be made from the crocus.

Diaphoretic ANTIMONY.—One part of antimony and two and a half or three of nitre, mixed together and deflagrated, yield a calx void of all emetic power, called diaphoretic antimony.

The martial Diaphoretic ANTIMONY, or *Specific Stomachic of Poterius*, is prepared by melting equal parts of antimony and iron filings, injecting upon them in fuſion thrice their weight of powdered nitre, and after the detonation is over, edulcorating and drying the calx. The jovial diaphoretic antimony, or antihectic of Poterius, is made in the ſame manner, from a mixture of tin and martial regulus of antimony, in the proportion of one part of tin to four of the regulus. This preparation has no claim to antihectic virtues, nor indeed to any ſalutary operation.

Regulus of ANTIMONY.—The ſimple regulus of antimony is commonly prepared from equal parts of antimony, nitre, and tartar, mixed together and injected into a red-hot crucible: when the whole is thrown in, the crucible is to be covered, a ſtrong fire kept up for a quarter of an hour, and the matter poured out into a conical mould, previouſly warmed and rubbed with greaſe. The yield of regulus will be larger, if the quantity of nitre is diminiſhed; or if the nitre and tartar are deflagrated together, in the proportion of one part of the former or two of the latter, before their mixture with the antimony. The ſalts are reduced by the deflagration into a black alkaline coal; this is the ſubſtance commonly uſed by the chemiſts for promoting the fuſion of metallic calces, and reviving them into their metallic form, and hence is diſtinguiſhed by the name of black flux. Some have been accuſtomed to ſave the expence of nitre, by taking pot-aſh or other alkaline ſalts: the regulus is in both caſes the ſame. When the matter is grown cold, the ſcoriæ found on the ſurface are knocked off, the regulus reduced into coarſe powder, melted in a freſh crucible, and about one fourth its weight of purified nitre injected upon it; this depuration may be twice or thrice repeated with ſmaller proportions of nitre, till the ſcoriæ become ſemitranſparent and of an amber colour.

Martial Regulus of ANTIMONY. This preparation is obtained very commodiouſly from four parts of powdered antimony, two parts of iron nails or wire, and one part of nitre. The iron, made red-hot in a crucible, ſoon melts upon adding the antimony; after which the nitre is to be injected, the crucible covered, and the matter, when brought into thin fuſion, poured expeditiouſly into a warm greaſed cone. The regulus freed from the ſcoriæ, is to be melted afreſh, with about one fourth its weight of nitre; and this purification, if neceſſary, repeated. If the regulus retains any ſuperfluous iron, it will look greyiſh, ſpongy, prove hard to break, and difficult of fuſion: in ſuch caſe, the ſcorification of all the iron, by means of nitre, would be a tedious work; but the addition of a little crude antimony, or common ſulphur, will abſorb it at once; and the injection of nitre will now ſoon complete the purification, and render the regulus of a ſparkling white colour. The ſcoriæ are yellow and ſemitranſparent, like amber; if the quantity of nitre has not been too large, they prove an exceſſively ſtrong fiery alkali, diſtinguiſhed by the name of nitrum cauſticum. The yellow ſcoriæ, which ſeparate in the depuration of the ſimple regulus with nitre, are likewiſe alkaline, but want the cauſticity of theſe: the ſcoriæ produced from the martial regulus, by calcination with tartar, take fire on being expoſed to the air. If either regulus, after due purification, be haſtily poured into the mould whilſt in exceeding thin fuſion, and if the quantity of ſcoriæ covering the ſurface is conſiderable, the regulus, when grown cold, exhibits the appearance of a ſtar upon the top. For producing this appearance, there is no occaſion for any particular ſort of antimony, or any particular iron, or any particular conſtellation, or ſeaſon, or weather, as many have idly imagined; the whole depending upon the circumſtance abovementioned.

The ſimple regulus is caſt into cups, which, like thoſe made from the glaſs, communicate an emetic quality to wines; and into pills, like ſhot, which prove ſtrongly purgative, and do not loſe their virtue in paſſing through the body; whence their name pilulæ perpetuæ.

Tincture of ANTIMONY.—There are various tinctures of antimony, which ſome have fondly imagined to participate of ſolar, venereal, antimonial, and other impregnations. They appear to be all no other than ſimple alkaline tinctures; their colour proceeding from the oily matter of the ſpirit of wine, heightened by the cauſtic alkali. Spirit of wine conſiſts of an oil highly attenuated and combined with water into one ſeemingly homogene liquor: if the moſt highly rectified ſpirit, which exhibits no mark of any phlegm, be employed for making theſe tinctures, it will now yield in diſtillation a good quantity of water; the oil, before combined with that water, having been abſorbed by the alkali. If cauſtic alkaline ſalt, alone, be poured hot into rectified ſpirit, and the mixture digeſted for ſome time, a tincture will be obtained, not diſtinguiſhable from the antimonial. If ſulphur be added in either caſe, the tincture will receive a conſiderable taſte and ſmell from that ingredient.

ANTINOMIANS, in eccleſiaſtical hiſtory, certain heretics, who firſt appeared in the year 1535.

The word is formed from the Greek, αντι, againſt, and ονομος, a law.

They were ſo called, becauſe they rejected the law, as of no uſe under the Goſpel diſpenſation. They held, that good works do not further, nor evil hinder, ſalvation; that the child of God cannot ſin; that God never chaſtiſes any land for their ſins; that murder, adultery, drunkenneſs, and the like, are no ſins in the children of God; that an hypocrite may have all the graces that were in Adam before his fall; and the like ſtrange opinions.

ANTIPARALLELS, in geometry, are thoſe lines as FE, BC, (plate XV. *fig.* 1.) that make the ſame angles AFE, ABC, with the two lines AB, AC, cutting them, but contrary ways, as parallel lines that cut them. When the ſides AB, AC, of a triangle, as ABC, are cut by a line EF, antiparallel to the baſe BC, the ſides are cut reciprocally proportional by the ſaid line EF, that is AF : BF :: EC : AE, the triangles AFE, ABC, being ſimilar.

If an oblique cone, having a circle for its baſe, be cut by a plane antiparallel to its baſe, the figure of the ſection will be a circle. See CONE.

ANTIPATHY, a natural averſion of one body to another; the oppoſite to ſympathy.

The word is Greek, αντιπαθεια, and compounded of αντι, againſt, and παθος, affection.

ANTIPERISTALTIC *Motion of the Inteſtines*, is a motion directly oppoſite to the periſtaltic. See the article PERISTALTIC.

ANTIPERISTASIS, in the peripatetic philoſophy, an imaginary method of increaſing the power or force of any quality, by the oppoſition of its contrary. Thus, cold is ſaid to augment the heat of fire; a doctrine now ſufficiently exploded.

The word is Greek, αντιπεριστασις, and compounded of αντι, about, and περιστημι, to encompaſs, or ſurround.

ANTIPHONY, alternate ſinging; as when a congregation, divided into two parts, repeats or ſings a pſalm or anthem, verſe for verſe, one after the other.

The word is compounded of the Greek, αντι, oppoſite, and φωνη, a voice.

Antiphony is oppoſite to ſymphony, which is ſinging jointly, or all together. St. Auſtin carries the original of this way of ſinging, in the weſtern church, no higher than the time of St. Ambroſe, when it was firſt introduced into the church of Milan; which example was ſoon followed by the other weſtern churches. What was the original of it in the eaſtern church, is not ſo certainly agreed upon by writers, either ancient or modern. It was a method of ſinging ſo taking and delightful, that it was often uſed, when only two or three were met together for private devotion. And Socrates particularly remarks of the emperor Theodoſius the younger, and his ſiſters, that they ſung alternate hymns together every morning in the royal palace.

ANTIPHRASIS, in rhetoric, a figure, by which, in ſaying one thing, they mean the contrary. See the article IRONY.

The word is Greek, and compounded of αντι, oppoſite, and φραζω, to ſpeak.

ANTIPODES, in geography, a name given to thoſe inhabitants of the globe that live diametrically oppoſite to each other.

The word is Greek, and compounded of αντι, oppoſite, and πους, a foot; becauſe their feet are oppoſite to each other.

The antipodes lie under oppoſite meridians and oppoſite parallels; in the ſame degree of latitude, but of oppoſite denominations, one being north, and the other ſouth. They have nearly the ſame degree of heat and cold, days and nights of equal length, but in oppoſite ſeaſons. It is noon to one, when midnight to the other; and the longeſt day with the one, is the ſhorteſt with the other.

We have ſaid the antipodes have nearly the ſame degree of heat and cold, not abſolutely the ſame of neceſſity; becauſe, firſt, there are many accidents to modify the action of the ſolar heat; ſo that people ſituated in the ſame climate, have not the ſame temperature of air. This may, in general, be accounted for by the interpoſition of mountains, the nearneſs or diſtance of the ſea, the winds, &c. Secondly, the ſun is not throughout the whole year at the ſame diſtance from the earth; it is ſenſibly at a greater diſtance in the month of June, than in January; from whence it follows, that, *conſideratis conſiderandis*, our ſummer in England is not ſo hot as that of our antipodes, and our winter leſs cold. Nay, ice is found in the ſeas of the ſouthern hemiſphere, at a much leſs diſtance from the equator, than in thoſe of the northern hemiſphere.

The horizon of one place being 90 degrees diſtant from the zenith of the other, it follows, that the antipodes have the ſame horizon; it follows alſo, that when the ſun riſes to the one, he ſets to the other.

Plato is eſteemed the firſt who thought it poſſible that the antipodes ſubſiſted, and is looked upon as the inventor of the word. As this philoſopher apprehended the earth to be ſpherical, he had only one ſtep to make to conclude the exiſtence of the antipodes.

The ancients, in general, treated this opinion with the higheſt contempt; never being able to conceive how men and trees could ſubſiſt ſuſpended in the air with their feet upwards; for ſo they apprehended they muſt be in the other hemiſphere.

They never reflected that theſe terms, upwards and downwards, are merely relative; and ſignify only nearer to, or farther from, the center of the earth, the common center to which all heavy bodies gravitate; and that, therefore, our antipodes have not their feet upwards and head downwards any more than ourſelves; becauſe they, like us, have their feet nearer the center of the earth, and their heads further from it. To have the head downwards and feet upwards, is to place the body in a direction of gravity tending from the feet to the head; but this cannot be ſuppoſed with regard to the antipodes; for they, like us, tend towards the center of the earth, in a direction from head to foot.

If credit may be given to Aventinus, Boniface, archbiſhop of Mentz, and legate of pope Zachary, in the eighth century, declared one Virgil, a biſhop in that age, a heretic, for having dared to maintain there were antipodes.

We have conſidered the antipodes here as being placed diametrically oppoſite to the terreſtrial globe; ſo that a perpendicular or vertical line being drawn through any place whatever, and which conſequently paſſes through the zenith of that place, the oppoſite part on the ſurface of the globe, which this vertical line continued would cut, is the ſituation of the antipodes to that place: this depends on a ſuppoſition of the earth's being a perfect ſphere; for if the earth be not a perfect ſphere, but an oblate or prolate ſpheriod, there are no reciprocal antipodes: that is, for inſtance, if a line be drawn through the zenith of London, and center of that city, which is in the northern hemiſphere, this line would cut the ſouthern hemiſphere in a point which will be diametrically oppoſite to London; but London then will not be the antipodes to this place. Thus the reciprocal equality of ſituation, latitude, day and night, in the oppoſite hemiſpheres at ſix months diſtance, and all that we are uſed to include in the idea of antipodes, as inſeparable from it, is no longer ſo; and muſt alter, in proportion as the figure of the earth deviates from a true ſphere. A little attention will convince us of this.

What we have advanced is founded on this poſition, that the ſphere, or, to render the theory more ſimple, the circle, is the only regular figure which all diametrical lines drawn through the center cut at right angles: therefore, in every figure terminated by another kind of curve, to inſtance in the ellipſis, the perpendicular drawn to one of its foci, or to its tangent, except the two axes which correſpond to the polar line, or a diameter drawn at the equator, will not paſs through the center, nor cut the oppoſite part of the ellipſis at right angles; therefore the nadir of Paris or London is not the zenith of their reſpective antipodes. So if, in the center of London or Paris, a perpendicular column were erected, and another in their reſpective antipodes, it would not make the ſame right-line, but would form an angle more or leſs acute, in proportion as the ellipſis departed more or leſs from a circle; and, conſequently, the latitude, days, nights, ſeaſons, &c. would alter in the ſame proportion. Places ſituated under either pole, or on the equator, are excepted for the reaſon we have before ſuggeſted; becauſe, in the former caſe, it is one of the axes of the ellipſis that joins both foci, and in the latter it is always a circle, the other axis of which is the diameter of the ellipſis; the ſpheroid, however oblate or prolate, being always ſuppoſed to reſult from the revolution of the elliptical meridian round the axis of the world. See *Hiſt. Acad.* 1741.

ANTIPOPE, in the Romiſh church, implies a perſon elected pope in an irregular manner, in oppoſition to another.

ANTIPTOSIS, in rhetoric is a figure which puts one caſe for another.

The word is Greek, and compounded of αντι, oppoſite, and πτωσις, a caſe.

ANTIQUARIAN *Society*.—A ſociety of antiquaries was formed in the city of London, about the year 1580, by ſome of the moſt learned men in the kingdom; but, having been frequently interrupted and diſcontinued, very little can be ſaid concerning the ſame till the year 1717, when it was again revived by a number of gentlemen, ſtudious of antiquity in general, but more particularly deſirous to obtain all poſſible knowledge of the antiquities of their own country. With this view they agreed to meet one evening in every week under certain regulations; they encouraged correſpondencies with all parts of the kindom; they ſubſcribed an annual ſum to defray the expence of engraving on copper-plates, what ſhould be thought deſerving to be ſo preſerved, and limited their number to 100. And in this manner they continued their weekly meeting with great reputation, till his majeſty king George II. was graciouſly pleaſed to grant them a royal charter of incorporation, dated November 2, 1751; and to declare himſelf their founder and patron.

Under this charter they became a body corporate, by the name of the Society of Antiquaries of London, with a power to have and uſe a common ſeal, to ſue and be ſued, and to take, hold, and enjoy by purchaſe, gift, or otherwiſe, any lands, tenements, and hereditaments, not exceeding in the whole one thouſand pounds per annum. And it is therein directed, that the council of the ſaid ſociety ſhall at all times conſiſt of twenty-one perſons, the preſident, for the time being, always to be one; and Martin Folkes, Eſq; was by charter appointed the firſt preſident; and alſo twenty other perſons therein named to be the firſt council, empowering them, within two months from the date thereof, to nominate, chooſe, and admit, as fellows of the ſaid ſociety, ſuch perſons as ſhould excel in the knowledge of the antiquities and hiſtory of this and other nations, and be eminent for piety, virtue, integrity, and loyalty. This firſt preſident and council were to continue till the 23d day of April next enſuing, on which day, in every year hereafter, the council and fellows aſſembled to nominate and elect a preſident and council for the enſuing year; and it was particularly directed that eleven of the former council ſhould be continued, and ten other perſons choſen out of the members of the ſociety: ten and no more of the council being to be changed annually. The preſident is empowered to nominate four perſons of the council to be his deputies, and ſupply his place in caſe of ſickneſs or abſence; and the preſident, council, fellows, or any twenty-one, or more, are empowered to make ſtatutes, rules, orders, and bye-laws, for the government and direction of the ſaid ſociety, their eſtates, goods, &c. and for the admiſſion and amoval of all and every the members and officers thereof. And the preſident, council, and fellows, may at any time appoint treaſurers, ſecretaries, and clerks, may have and employ one ſerjeant at mace, and ſuch other ſervants as they think neceſſary. And laſtly, if at any time abuſes or differences ſhould ariſe, the archbiſhop of Canterbury, the lord chancellor or keeper of the great ſeal, and the lord privy ſeal, and the two ſecretaries of ſtate for the time being, were appointed viſitors, with the full power for any three of them to compoſe and redreſs ſuch differences and abuſes: proviſion is alſo made to fill up any vacancies that ſhould happen by the death of the preſident or any of the council.

On the receipt of this charter, the firſt preſident and council nominated and admitted, by a writing dated the 14th of November, 1751, all the former members, together with ſome others, in the whole one hundred and twenty-one, to be fellows of the ſaid Society of Antiquaries of London; and ſoon after drew up a body of ſtatutes for the good government thereof, which was unanimouſly agreed to and confirmed in the month of July 1752.

It was enacted, that the number of members ſhould not exceed one hundred and fifty; but that number being very ſoon filled up, and ſeveral men of quality and fortune, as well as perſons of great learning and eminence, being continually applying to become members, which they could not be till the vacancies ſhould happen by death, the ſociety thought proper, in the year 1755, to enlarge their number to one hundred and eighty, (to which they are limited at preſent) excluſive of peers, privy-counſellors, and judges, that ſhould be choſen after that time. A little before this, the ſociety gave up the management of their eſtates and revenues, the payment of monies, and the publication of their papers and drawings, which before were in the body in general, and thereby attended with many inconveniences, entirely to the care of their council, which are now a ſtanding committee for that purpoſe; and thereby the government of this ſociety is become nearly the ſame as that of the Royal Society, which was doubtleſs a proper pattern to copy after.

On the 23d of April, being St. George's day, the ſociety annually elect their council and officers, viz. a preſident, a treaſurer, two ſecretaries, and a director, who has the care of all their publications. Then the preſident appoints four of the council to be his deputies, or vice-preſidents: and after the election is over, the ſociety dine together at their own expence. Martin Folkes, Eſq; was annually elected preſident, till his death in 1754, ſince which time the Right Hon. Lord Willoughby of Parham was every year choſen 'till his deceaſe in 1765.

Every perſon deſirous to be elected a fellow of this ſociety, except peers, privy-counſellors, or judges of Great-Britain or Ireland, muſt be recommended by three or more of the members, in a paper ſigned by themſelves, ſpecifying the name, addition, profeſſion, and chief qualification of the candidate, and alſo the place of his abode. When this has been read at one of the ſociety's meetings, and then hung up in their public room, during the time of four other meetings, the election is determined by ballot. Peers, privy-counſellors, and judges of Great-Britain or Ireland, if propoſed by any ſingle member, muſt be ballotted for immediately. Every new member muſt pay an admiſſion-fee of five guineas, and ſign the obligation, whereby he promiſes that he will, to the utmoſt of his power, promote the honour and intereſt of the ſociety, and obſerve the ſtatutes and orders thereof: which being done, he is led up to the chair, when the preſident or vice-preſident riſing, takes him by the hand and ſays, “I do by the authority and in the name of “the ſociety of antiquaries of London, admit you a “fellow thereof.”

Every member muſt further pay one guinea annually for the uſe of the ſociety, or ten guineas at once in lieu of all contributions.

The meetings of this ſociety are on Thurſday evenings weekly, from about ſix till nine o'clock, at their houſe in Chancery-Lane. Their buſineſs is to receive, read, and conſider all informations from their own members, or others, concerning the antiquities of all nations; (for which purpoſe they admit eminent foreigners to be correſponding members) but they more particularly attend to the ſtudy of the ancient hiſtory, cuſtoms, manners, grants, charters, coins, medals, camps, churches, cities, and all monuments whatever, eccleſiaſtical, military, or civil, which are found in or relate to Great Britain and Ireland; and the communications they have received concerning theſe matters muſt be very valuable, as may be judged by the many curious remains of antiquity they have cauſed to be engraved on copper-plates, and permitted lately to be ſold; though as yet they have not thought fit to publiſh any of their diſſertations. They have a ſmall, but choice, library, which is increaſing daily; alſo a fine collection of prints and drawings.

ANTIQUARY, a perſon who ſtudies and ſearches after remains of antiquity.

ANTIQUE, a term moſt in uſe among architects, ſculptors, and painters: they make uſe of it to expreſs pieces of architecture, ſculpture, or painting, executed in the ages when thoſe arts were carried to the higheſt perfection, by men of the fineſt genius in Greece and Rome; that is, from the age of Alexander the Great, to the reign of the emperor Phocas, about the year of our Lord 600, when Italy was over-run by the Goths and Vandals.

Antique in this ſenſe is oppoſed to modern; thus we ſay an antique edifice, buſto, baſſo relievo, or manner; an antique model; and of a ſtatue, that it is in an antique taſte.

We have ſeveral antique pieces of ſculpture left, as the Laocoon and Venus in the poſſeſſion of the family of Medicis, the Apollo and Hercules of the houſe of Farneſe, &c.

Antique paintings are more ſcarce; we have only the wedding of Aldobrandinus, ſome little figures of the pyramid of Ceſtius, a Venus which is the palladium of Rome, and ſome ſmall pieces in freſco, preſerved out of the ruins of the baths of Titus and Heraclius.

Some ſculptors have counterfeited antiques ſo nicely as to impoſe on the judgment of the public; witneſs the famous ſtory of Michael Angelo's Cupid.

Antique is ſometimes diſtinguiſhed from ancient, which means a leſs degree of antiquity, a time when the art was not in its higheſt perfection. Some writers uſe a compound word, antique-modern, in ſpeaking of old Gothic churches, and other buildings, which they would not confound with thoſe of the Greeks and Romans.

ANTIQUITY, *Antiquitas*; we make uſe of this term to denote paſt ages.

In this ſenſe we ſay, the heroes of antiquity, traces or veſtigia of antiquity, monuments of antiquity.

We make uſe of the ſame word to expreſs what is left us of the ruins, monuments, remains, &c. of the ancients.

In this ſenſe we ſay a maſter piece of antiquity; a fine piece of antiquity; Italy, France, and England, are full of antiquities. Antiquity is taken alſo for the ancientneſs of any thing, or the time it has ſubſiſted.

In this ſenſe we ſay, the antiquity of a kingdom, a cuſtom, or any thing of the like nature. Moſt nations pretend to a greater antiquity than they can prove. We may ſay, that the preſent time is the age of the world, and that in thoſe times which we call ancient, the world was only in its infancy.

ANTIRRHINUM, ſnap-dragon, or calf's ſnout, in botany, a genus of plants, with an anomalous flower, conſiſting of one leaf, which is divided, as it were, into two lips; the upper of which is cut into two parts, and the under into three parts: out of the flower-cup ariſes the pointal, faſtened like a nail in the hinder part of the flower, which afterwards turns to a fruit, reſembling a calf's head, which is divided in the middle by a partition into two cells, in which are contained many ſmall ſeeds. Botaniſts enumerate twelve ſpecies of this plant. All the ſorts of ſnap-dragon are pretty ornaments in a garden, and, requiring a very little culture, are rendered more acceptable. They are all hardy plants, and will reſiſt the cold of our winters extremely well, eſpecially if they are planted on a dry, gravelly, or ſandy ſoil; for, when they are planted in a rich moiſt ſoil, they will grow very luxuriant for a while, but are very ſubject to rot in autumn or winter; and are much more ſuſceptible of cold, than when they are in a dry, hungry, rocky ſoil; they will grow in the joints of old walls where they may be placed ſo as to make ſome abject part of the garden agreeable: for they will continue in flower for ſeveral months: and if the ſeeds are permitted to ſhed, there will be a continual ſupply of young plants, without any trouble.

Wherever thoſe plants are deſigned to grow upon walls, or on a rocky barren ſoil, the ſeeds ſhould be ſown the beginning of March, where they are deſigned to remain (for if the plants are firſt raiſed in a better ſoil, and afterwards tranſplanted into thoſe places, they ſeldom ſucceed well). When the plants are come up, they will require no other culture, but to keep them clear from weeds; and where they come up too thick, to pull ſome of them out; ſo as to give them room to grow. In July theſe ſorts will begin to flower, and will continue flowering till the froſt prevents them. Thoſe plants which grow on walls, will be ſtrong, and have woody ſtems, which will continue two or three years or more. *Miller's Gard. Dict.*

ANTISAGOGE, in rhetoric, the ſame with conceſſion. See the article CONCESSION.

ANTISCII, in geography, perſons who live on different ſides of the equator.

The word is compounded of the Greek, αντι, againſt, and σκια, a ſhadow.

ANTISCORBUTICS, among phyſicians, medicines good in all ſcorbutic caſes. See SCURVY.

ANTISEPTICS, among phyſicians, a name given to all ſubſtances that reſiſt putrefaction.

The word is formed from the Greek, αντι, againſt, and σηπω, to putrefy.

Dr. Pringle, in an appendix to his Obſervations on the Diſeaſes of the Army, has given a very curious and uſeful ſet of experiments on antiſeptics.

ANTISIGMA, among the ancient grammarians, implies a note or ſentence affixed to thoſe verſes whoſe order was to be changed.

ANTISTROPHE, in the ancient drama, implies the ſtanza repeated by the chorus to the audience on the left-hand; the word being derived from αντι, againſt, and ςρεφω, to turn. Thus the ſtrophe ſignifies the ſtanza, or thoſe verſes which the chorus ſing, turning themſelves towards the ſpectators on the right hand; and the antiſtrophe means the ſame ſtanza ſung by the chorus turning themſelves towards the audience on the left. In rhetoric, the antiſtrophe or epiſtrophe ſignifies repartee; as for example, if, after having ſaid the man of ſuch a maſter, we add, and the maſter of ſuch a man; this laſt phraſe is an antiſtrophe, or expreſſion, in reply to the firſt: a famous paſſage of St. Paul, in his 2d Epiſt. to the Cor. chap. xi. v. 22, is expreſſed in this figure of rhetoric. Ἑβραιοι εισι; καγω. Ισραηλιται εισι; καγω. σπερμα Αβρααμ εισι; καγω. Are they Hebrews? ſo am I. Are they Iſraelites? ſo am I. Are they the ſeed of Abraham? ſo am I.

This is alſo a term uſed in ancient lyric poetry: among the Greeks, the antiſtrophe made one of the three parts of their ode: the other two were called the ſtrophe and epode. The ſtrophe and antiſtrophe always contained an equal number of verſes, and thoſe too of the ſame meaſure, which could conſequently be ſung to the ſame muſic: but the epode was compoſed in verſes of a different meaſure, either longer or ſhorter. The antiſtrophe was a kind of anſwer or relative echo, both to the ſtrophe and the epode; the Greeks called theſe three united, a περιωδη, and is the ſame thing that we ſhould call a ſong of three ſtanzas.

ANTITACTES, in eccleſiaſtical hiſtory, a name given to a branch of the Gnoſtics, who held, that God was good and juſt; but that a creature had created evil: that we are therefore to oppoſe this author of evil, in order to avenge God of his enemy.

The word is derived from the Greek, αντιταττειν, to oppoſe.

ANTITHENAR, in anatomy, the name of a muſcle, generally called adductor indicis. See the article ADDUCTOR *Indicis*.

ANTITHESIS, in rhetoric, a figure of ſpeech which conſiſts in oppoſing the thoughts to each other, in order to place their oppoſite qualities in a more conſpicuous point of light.

The writings of the ancients abound with this figure. Cicero, in his oration for Cluentius, ſays, *Vicit pudorem libido, timorem audacia, rationem amentia.*

ANTITHESIS, in grammar, is a figure whereby one letter is ſubſtituted in the room of another; as when Virgil ſays *olli* for *illi*, in order to make a kind of oppoſition.

ANTITHETARIUS, a term occurring in the title of a chapter of the laws of Canutus, but not in the chapter itſelf. It ſignifies a perſon who endeavours to acquit himſelf of the crime laid to his charge, by charging his accuſer with the ſame fact.

ANTITRAGUS, in anatomy, the part of the external year oppoſed to the tragus. See EAR and TRAGUS.

ANTITRINITARIANS, a general name given to all thoſe who deny the Chriſtian doctrine of the Trinity; but particularly applied to the Arians and Socinians.

ANTITYPE, a Greek word, properly ſignifying a type or figure. In this ſenſe St. Paul uſes the word, Heb. ix. ver. 24, where he ſays, that Jeſus is not entered into the holy of holies made with hands, which was the type of the true. Inſtead of the word type, we read in the Greek of St. Paul, antitype, which meſſieurs Port-Royal and Amelot have tranſlated type or figure. Thus, according to the true import of the word, it ſignifies a type which anſwers to another type, or rather that which is in the place of a type.

ANTITYPE, in the Greek church, is an appellation given to the bread and wine, even after conſecration: and hence it has been argued, that they do not believe tranſubſtantiation; for otherwiſe they could not, with any propriety, call the bread and wine antitypes, figures, or ſimilitudes after conſecration.

ANTLER, among ſportſmen, implies a ſtart or branch of a deer's horn.

Brow ANTLER ſignifies the branch next the head.

Bes ANTLER, the branch next above the brow antler.

ANTŒCI, in geography, thoſe inhabitants of the earth who live under the ſame meridian, and at the ſame diſtance from the equator, the one towards the north, and the other towards the ſouth.

The word is formed from the Greek, *αντι*, oppoſite, and *οικεω*, to dwell.

The Antœci have exactly the ſame hours of the day and night, but oppoſite ſeaſons; the ſhorteſt winter's day of the one being the longeſt ſummer's day with the other; and conſequently the length of the night with the one, is equal to the length of the day with the other.

Tower of ANTONIA, in antiquity, the moſt magnificent monument which Herod the Great ever built; he gave it that name in memory of Antony his friend: it was built on the hill of Jeruſalem formerly called Barri. The front of it was built entirely of white marble, and defended by a wall of three cubits high; the diſtance of this wall to the tower was forty cubits; within it were contrived halls, apartments, and baths. At equal diſtances were four other towers, three of which were fifty cubits high; and the fourth, which took up the ſouthern and eaſtern angles, was of ſeventy cubits. Theſe towers had galleries communicating with the temple ſtairs, from whence the Roman ſoldiers uſed to obſerve the people on feſtival days, to ſee that they did not form any dangerous enterprize.

ANTONIAN *Water*, in the materia medica, the name of a medicinal water of Germany, remarkably pleaſant to the taſte, and of ſervice in many caſes as a medicine.

It is very temperate, not too ſtrongly operating either by ſtool or urine: and hence it is a very proper drink for perſons in chronic and many acute diſeaſes, either alone, or mixed with wine, to ſupply the place of malt liquor, which is proper but in very few diſeaſes. A long uſe of it alone may alſo prove of conſiderable ſervice in hypochondriac caſes. *Hoffman's Oper.*

ANTONOMASIA, in rhetoric, a figure by which the noun appellative is uſed inſtead of a proper name, and the contrary.

The word is compounded of the Greek, *αντι*, for, and *ονομα*, a name.

Thus, becauſe Sardanapalus was a voluptuous prince, and Nero a cruel emperor, we give an epicure the name of Sardanapalus, and a barbarous prince the appellation of Nero.

ANTRUM *Highmorianum*, in anatomy, is a cavity diſcovered in the maxillary bone, called alſo ſinus maxillaris.

ANTRUM *Pylori*, in anatomy, is a large cavity at the bottom of the pylorus. See PYLORUS.

ANUBIS, in mythology, a name given to Mercury, who was worſhipped by the Egyptians under the figure of a dog.

Diodorus Siculus tells us, that Anubis, following his father Oſiris to war, bore the enſign of a dog on his ſhield; for which reaſon he was worſhipped, after his death, under the figure of a dog.

ANVIL, in mechanics, a ſmith's utenſil, on which the work is forged or hammered.

The face or uppermoſt ſurface of the anvil muſt be very flat and ſmooth, without flaws; and ſo hard that a file will not touch it. At one end is ſometimes a pike, bickern, or beak-iron, for the rounding of hollow work. The whole is uſually mounted on a firm wooden block.

Forged anvils are better than thoſe of caſt-work. Lockſmiths have alſo a ſmaller kind of anvil, called a ſtake, which is moveable, and placed ordinarily on their work-bench. Its uſe is for ſetting ſmall cold work ſtraight, or to cut or punch on with the cold chiſſel or cold punch. See the articles LOCKSMITH and SMITHERY.

ANUS, in anatomy, the extremity of the inteſtinum rectum, or orifice of the fundament. It is ſurrounded with a large quantity of fat, that it may eaſily dilate in diſcharging its contents, and is furniſhed with three muſcles, called elevatores and ſphincter. See SPHINCTER.

ANUS is alſo the name of a ſmall aperture in the third ventricle of the brain, leading to the fourth ventricle of the cerebellum.

AONIDES, in mythology, one of the many appellations of the muſes, ſo called from the Aonian mountains in Bœotia, where they were feigned to reſide.

AORASIA, in antiquity, the inviſibility of the gods.

The word is Greek, *αορασια*, and derived from *α*, priv. and *οραω*, to ſee.

The opinion of the ancients, with regard to the appearance of the gods to men, was, that they never ſhewed themſelves face to face, but were known from their backs as they withdrew: whence it followed, according to them, that every being they had time to look at in the face, was not a deity. Neptune aſſumed the form of Calchas to ſpeak to the two Ajaxes; but they knew him not till he turned his back to leave them; and diſcovered the god by his majeſtic ſtep, as he went from them. Venus appeared to Æneas in the character of a huntreſs; but her ſon knew her not till ſhe departed from him; her divinity was betrayed, if we may uſe the word, by her radiant head, her flowing robe, and her majeſtic pace.

AORISTUS, in the Greek grammar, an indefinite or indeterminate kind of tenſe, which ſometimes expreſſes the preſent time, ſometimes the future, but moſt frequently the paſt.

The word is Greek, Αοριϛος, and compounded of *α*, priv. and *οριζω*, to bound or limit.

AORTA, in anatomy, the great artery which riſes immediately from the left ventricle of the heart, and thence diſtributed to all parts of the body. It is divided into two grand trunks, diſtinguiſhed by the epithets aſcending and deſcending. See the article ARTERY.

APAGOGICAL *Demonſtration*, implies an indirect method of proving the truth of a propoſition, by ſhewing the abſurdity of the contrary.

The word is formed from the Greek, *απο*, from, and *αγω*, to bring, or draw.

APANAGE, or APENNAGE, in the French cuſtoms, are lands aſſigned by the ſovereign for the ſubſiſtence of his younger ſons, and which revert to the crown upon failure of male iſſue in that branch to which the lands were granted.

APARINE, gooſe-graſs, or cleavers, in botany, a plant with a ſlender fibrous root; and ſlender, quadrangular, geniculated, rough, climbing ſtalks, five or ſix feet long. At every genicula, or knee, there are from five to ſeven leaves placed like a ſtar, which are narrow, rough, and terminate in prickles. The flowers proceed from the knees towards the top, and are very ſmall, white, monopetalous, in the ſhape of bells, and divided into four ſegments, as well as the flower-cup, which turns into a dry, hard, cartilaginous fruit, covered with a thin blackiſh ſkin; and they conſiſt of two globes full of umbilicated ſeeds. It is met with almoſt every where in hedges. It is inciding and aperient, and not only promotes urine, but ſweat; two ounces of the juice have been found to be very ſerviceable in the dropſy, carrying off the water by urine.

APARTMENT, a portion, or part of an houſe, containing the neceſſary conveniencies for a perſon to reſide in it.

APATHY, among the ancient philoſophers, implied an utter privation of paſſion, and an inſenſibility of pain.

The word is compounded of *α*, priv. and *παθος*, affection.

The Stoics affected an entire apathy; they conſidered it as the higheſt wiſdom to enjoy a perfect calmneſs or tranquillity of mind, incapable of being ruffled by either pleaſure or pain.

The primitive Chriſtians uſed the word to expreſs a contempt for the things of this world.

APATURIA, in antiquity, a ſolemn feaſt celebrated by the Athenians in honour of Bacchus.

APE, in natural hiſtory, the Engliſh name of an animal of the monkey kind.

It is hairy all over the body, and has ſome reſemblance to a man in the face, noſtrils, ears, and teeth. It has alſo eye-laſhes on both the eye-lids; whereas other quadrupeds have none, except on the upper. On the breaſt it has paps, and the arms are like thoſe of a man, but hairy, and he bends them as well as the feet, like a human creature. Beſides, it has hands, fingers, and nails, like thoſe of a man, but more rough and unpoliſhed. The feet are like larger hands, and are divided into fingers, or toes, of which the middle finger is the longeſt.

An ape, properly ſo called, is without a tail; and thoſe that have tails go under the name of monkeys, of which there are ſeveral kinds. See Monkey.

APEEK, in navigation, the anchor is ſaid to be apeek when ſo much of its cable is drawn or heaved into the ſhip, as to bring her ſtem perpendicular to it.

APELLITES, in eccleſiaſtical hiſtory, a ſect of Chriſtian heretics in the ſecond century, who affirmed that Chriſt received a body from the four elements, which at his death he rendered back to the world, and conſequently aſcended into heaven without a body.

APEPSY, *Apepſia*, among phyſicians, implies crudity, or a want of digeſtion.

The word is Greek, and compounded of α, priv. and πεπτω, to concoct.

APERIENS *Palpebram rectus*, in anatomy, a muſcle in the eye-lid. It ariſes ſharp and fleſhy from the profoundeſt part of the orbit, near the place where the optic nerve is tranſmitted, paſſing directly over the muſculus attollens; it becomes tendinous, as it marches over the ball of the eye; whence it ſtill grows broader and thinner, till it is inſerted into the whole ſuperior part of the upper eye-lid.

APERIENTS, in the materia medica, ſuch medicines as facilitate the circulation of the juices in their containing veſſels, by removing all obſtructions. See the article Deobstruents.

APERTURE, the opening of any thing, or a hole, cleft, or vacant place in ſome continuous ſubject.

The word is Latin, *apertura*, and derived from *aperio*, to open.

Aperture, or Apertion, in architecture, implies ſome opening, as a door, window, chimney, &c.

There ſhould be as few apertures as poſſible; it being a maxim that every aperture or opening has a tendency to weaken the building.

Aperture, in geometry, the opening of two right lines, which, inclining towards each other, meet in a point and form an angle.

Aperture, in optics, is the hole next the object glaſs of a teleſcope, or microſcope, through which the light and image of the object come into the tube, and are thence carried to the eye; it conſiſts of a turned bit of wood, or plate of tin, with a round hole of a convenient diameter in the middle thereof: this diameter may be found experimentally by applying ſeveral circles of black ſmutted paper, each bigger than the other, upon the face of the glaſs, from the breadth of a ſtraw to ſuch as leave only a ſmall hole in the glaſs; and with each of theſe, ſeparately, view ſeveral diſtinct objects, as the moon, ſtars, &c. That through which they appear the moſt diſtinctly is to be pitched upon.

Aperture is alſo underſtood of that part of the object glaſs itſelf, which covers the former, and which is left pervious to the rays. See Telescope.

M. Auzout affirms, that he found that the apertures of teleſcopes ought to be nearly in the ſubduplicate ratio of their lengths: but Huygens, who firſt introduced the uſe of apertures, aſſures us, he found, by experience, that the aperture of an object glaſs, ex. gr. of 30 feet, is to be determined by this proportion, as 30 to 3; that is, As 10 to 1, ſo is the ſquare root of the diſtance of the focus of any glaſs, multiplied by 30, to its aperture; and the focal diſtances of the eye-glaſſes are to be proportional to the apertures.

The greater or leſs aperture of an object glaſs, it is to be noted, does not increaſe or diminiſh the viſible area of the object; all that is effected by this is, the admittance of more or fewer rays, and conſequently the more bright or obſcure appearance of the object.

Hence, in viewing Venus through a teleſcope, a much leſs aperture is to be uſed than for the Moon, Jupiter, or Saturn; becauſe her light is ſo vivid and glaring: which conſideration does a little invalidate M. Auzout's proportion, as is ſhewn by Dr. Hook. *Philoſ. Tranſ.* N° 4.

Apertura *Tabularum*, in old law books, implies the opening a laſt will and teſtament.

APETALOSE, or Apetalous, among botaniſts, is an appellation given to ſuch plants as have no petals or flower leaves.

APEX, the vertex or ſummit of any thing. See Vertex.

APHÆRESIS, in grammar, is a figure by which a letter or ſyllable is cut off from the beginning of a word.

APHEA, in mythology, a goddeſs worſhipped by the Cretans and people of Ægina.

Aphea, before ſhe was made a deity, went by the name of Britomartis in Crete. Her paſſion for hunting attached her to the train of Diana, and dedicated her virginity to the goddeſs; to avoid the purſuit of Minos, who was deſperately in love with her, ſhe threw herſelf into the ſea, and was taken up in the nets of ſome fiſhermen. Diana rewarded her virtue with the honours of immortality. Britomartis afterwards appeared to the people of Ægina, who paid adoration to her under the name of Aphea.

APHELION, or Aphelium, in aſtronomy, that point of the earth's or a planet's orbit, in which it is the fartheſt diſtant from the ſun that it can be.

The word is Greek, formed of απο, from, and ηλιος, the ſun.

Thus, a planet being in A (plate XV. *fig.* 2.) its utmoſt diſtance from the ſun S, is ſaid to be in its aphelion.

The aphelia of all the primary planets are not at reſt; for thoſe of the planets neareſt the ſun, viz. Mercury, Venus, the Earth, and Mars, being acted upon by Jupiter and Saturn, move a ſmall matter in conſequentia, or according to the order of the ſigns; and that in the ſeſquiplicate ratio, or the ſquare roots of the cubes of the diſtances of thoſe planets from the ſun.

Hence, if the aphelion of Mars move 35 minutes in conſequentia, or according to the order of the ſigns, in 100 years, the aphelia of the Earth, Venus, and Mercury, will move, in 100 years, 18′, 36″, 11′, 27″, and 4′, 29″.

The method of finding the place of the aphelion is by obſerving ſeveral of the greater digreſſions of the planet from the ſun, till by two or three repeated obſervations it be found to remain at a ſtand.—In the Philoſ. Tranſ. N° 128, we have a geometrical method of finding the aphelia of the planets, given by Dr. Halley.

Kepler places the aphelion of Saturn, for the year 1700, in 28°, 3′, 44″, of Sagittarius: de la Hire, in 29°, 14′, 41″. The aphelion of Jupiter in 8°, 10′, 40″, of Libra: de la Hire, in 10°, 17′, 14″. The aphelion of Mars in 0°, 51′, 29″, of Virgo: de la Hire, in 0°, 35′, 25″. The aphelion of the earth in 8°, 25′, 30″, of Cancer. The aphelion of Venus in 3°, 24′, 27″, of Aquarius: de la Hire, in 6°, 56′, 10″. And the aphelion of Mercury in 15°, 44′, 29″, of Sagittarius: de la Hire, in 13°, 3′, 40″.

The annual motion, according to Kepler, of the aphelion of Saturn, is 1′, 10″, of Jupiter, 47″, of Mars, 1′, 7″, of Venus, 1′, 18″, and of Mercury, 1′, 45″. According to De la Hire, that of Saturn is 1′, 22″, of Jupiter, 1′, 34″, of Mars 1′, 7″, of Venus, 1′, 26″, and of Mercury, 1′, 39′.

APHONIA, among phyſicians, implies a loſs of voice or ſpeech.

The word is Greek, and compounded of α, priv. and φωνη, voice.

APHORISM, a maxim, or principle of ſome ſcience; or a ſentence comprehending, in a few words, a great deal of matter.

The word is formed from the Greek, αφορισμος, and derived from αφοριζω, to chuſe, or ſeparate.

APHRODISIA, in antiquity, feſtivals in honour of the goddeſs Αφροδιτη, or Venus. There were ſeveral of theſe Aphrodiſia obſerved in divers parts of Greece; the moſt remarkable was that at Cyprus, firſt inſtituted by Cinyras, out of whoſe family certain prieſts of Venus were elected; and for that reaſon named κινυραδια. At this ſolemnity ſeveral myſterious rites were practiſed: all who were initiated to them offered a piece of money to Venus as an harlot, and received, as a token of the goddeſs's favour, a meaſure of ſalt, and a φαλλος; the former, becauſe ſalt is a concretion of ſea water, to which Venus was thought to owe her birth; the latter, becauſe ſhe was the goddeſs of wantonneſs.

APHRODITE, a name of Venus.

The word is Greek, and derived from αφρος, foam; becauſe, according to the poets, Venus ſprung from the foam of the ſea.

APHRODITES, in natural hiſtory, a name given by ſome authors to the fineſt ſpecies of amethyſt.

The ancients had a way of diſtinguiſhing what they allowed to be gems, into ſeveral kinds, according to their degrees of colour: theſe they called ſo many ſpecies, and gave to each its particular name. This has been the occaſion of no little confuſion among the writers on theſe ſubjects, by ſeemingly enlarging the number of gems. The pæderos and gemma veneris of the ancients are the ſame ſtone with this, though many have applied theſe names to the opal.

APHRONITRE, in natural hiſtory, a name given by the ancients to a particular kind of natron, or native nitre; ſuppoſed to be the froth or ſpume emerging on the ſurface of nitre in fuſion.

The word is formed from the Greek, αφρονιτρον, and compounded of αφρος, froth, and νιτρον, nitre.

APHTHÆ, in medicine, ſmall round ſuperficial ulcers ariſing in the mouth.

The word is derived from the Greek, απτω, to inflame.

Mel roſarum, or honey of roſes, acidulated with ſpirit of vitriol, is a good medicine in the cure of the aphthæ.

APIARY, a bee houſe, or place where bees are kept, and properly furniſhed with all the apparatus neceſſary for that purpoſe.

The word is formed from the Latin, *apis*, a bee.

Methods of making an APIARY.—When there are but few bees, it is uſual to ſet them in any corner of the garden, or court, and ſometimes in cloſes adjoining to the houſe; though ſome, for want of room without doors, have ſet them in lofts or upper rooms; but this is not ſo proper for them. If a perſon intends to have a conſiderable ſtore of bees, a ſquare plat muſt be made by itſelf, proportioned to the number of bees intended to be kept, not quite a ſquare, being rather longer extended from eaſt to weſt, but ſo contrived that they may have as much of the morning and evening ſun as poſſible. The apiary ſhould be ſecurely defended from high winds on either ſide, either naturally by hills, trees, &c. or artificially by houſes, barns, walls, &c. It is alſo to be well fenced from cattle, eſpecially hogs, and from all ſorts of fowl, their dung being very prejudicial to them; neither ſhould there be any ill ſmells, nor any poultry kept near the place. The apiary ſhould be furniſhed with ſtools or benches, of wood or ſtone; but the firſt is beſt, ſtone being hot in ſummer, and cold in winter: theſe are placed at different heights, but about twelve inches is a good height; they ſhould be ſet a little ſhelving, that the rain may run off; they ſhould alſo be two or three inches wider than the hives ſet upon them, and at leaſt five feet diſtant from the other.

To have a compleat apiary, for every ſtock of bees intended to be kept, make a cot or houſe about two feet ſquare, and two and a half high, ſet on four legs about ten inches above the ground, covered over with boards or tiles to keep off the rain, the back or north ſide being cloſed up; and the ſides, facing the eaſt and weſt, to have doors with latches and haſps to them; the fore or ſouth ſide to have a falling door to cover one half thereof, which is to be raiſed up at pleaſure; and in ſummer-time ſerves for a pent-houſe, not only to keep off the beating rains from the hives, but to defend them from the extreme heat of the ſun, which at noon-day is apt to melt the honey. The other lower half ſhould have two ſmall doors to open to either hand, which will ſerve to defend the doors or holes of the hives from injurious winds: all the doors may be faſtened in winter, when the weather is too cold; or in ſummer, when it is too hot for the bees, only making a little open ſquare at the bottom of the little doors againſt the bee-hole, that the bees may have ſome liberty to fly abroad, after the doors have been ſhut: by means of the ſide doors, eſpecially if the weſt door be made to open to the right hand, a perſon may ſit ſafe, and ſee the ſeveral workings of the bees in glaſs hives, if any ſuch are uſed; if not at theſe places he may order, view, and obſerve them better than when they ſtand on naked ſtools, and with leſs offence to the bees, and more ſecurity to himſelf.

In the winter ſeaſon, if the apiary ſtand cool, good ſweet ſtraw may be ſtuffed within the doors about the hives, to keep them warm; but extremity of cold does not hurt bees ſo much in winter as wet, from which theſe caſes beſt preſerve them; or as light, and the warm beams of the ſun, at ſuch time when there is no proviſion abroad for them, againſt which this houſe or cot is the beſt preſervative; for, when the doors are ſhut, though the ſun ſhine, yet they are inſenſible of it, the hives ſtanding ſix or eight inches within the doors; whereas, after the common way of benches or ſtools, the ſun caſts rays to their very doors, which warmth, and light together, draw them out, at the expence of their proviſions and lives together, as is evident from frequent experience, the mildeſt and cleareſt winters ſtarving and deſtroying moſt bees; when, on the contrary, the coldeſt and moſt frozen beſt ſecure them. See the article BEE.

APICES, in botany, little knobs growing on the tops of the ſtamina, or cives in the middle of flowers.

The word is Latin, being the nominative plural of *apex*.

APIOS, the knobbed-rooted Virginian liquorice vetch, in botany, a genus of plants, whoſe characters are: it has a climbing ſtalk; the leaves grow almoſt oppoſite, and faſtened, as it were, to the mid-rib; the root is tuberous.

There is, at preſent, but one ſpecies of this plant known to us, which is, apios Americana Cornuti; the American apios of Cornutus.

This plant hath large knobbed roots, which part as they grow old, by which means the plant is increaſed; for it rarely produces ripe ſeeds with us. It is hardy, and will endure the cold in the open ground, if planted on a dry ſoil; but is ſubject to rot with too much wet in winter: it dies to the root every autumn, and riſes again the ſucceeding ſpring; and will twiſt itſelf round a pole, and grow to the height of eight or ten feet, and produce, in July, fine ſprigs of flowers: it hath alſo been planted near arbours, where it hath covered them very well towards the latter end of ſummer; but is cut down with the firſt cold of autumn: and in ſevere froſts the roots are often deſtroyed, where they are not well covered with litter or tanner's bark; for want of this precaution, moſt of the roots of this plant were deſtroyed in the hard winter, 1739-40. *Miller's Dict.*

APIS, in mythology, a famous deity among the Egyptians, repreſented by an ox, with certain external marks. Into this animal, according to the Egyptians, the ſoul of the Great Oſiris retired, and withdrew itſelf from the world. He gave this creature the preference, becauſe the ox is the ſymbol of agriculture, the perfection of which this prince had very much at heart.

The ox, Apis, muſt have a ſtar in the forehead; that is, a ſquare white mark, the figure of an eagle on his back, a knot under his tongue in the form of a beetle, the hair of his tail double, and a creſcent on his right flank; and the cow that bore him muſt have conceived by a clap of thunder.

As it is difficult to apprehend nature ſhould produce an animal with all theſe marks, requiſite for an Apis, we muſt ſuppoſe that the prieſts took care, by impreſſing the neceſſary marks on young calves, to be provided always with one: and if it happened at any time an Apis could not immediately be found, and they were obliged to put it off for ſome time, it was certainly becauſe they were very careful not to be thought guilty of the impoſition. But this artifice ſeems needleſs; people, on theſe occaſions, voluntarily ſhut their eyes. When they had found the Apis, before they carried him to Memphis, they fed him forty days in a city on the Nile. Women only were permitted to ſee and wait upon him, and theſe were obliged to preſent themſelves before the divine ox in an undreſs. After theſe forty days, they put him on board a ſuperb veſſel, and brought him down the Nile to Memphis, where the prieſt received him with all imaginable pomp; they were attended by numbers of people, and children were happy who could ſmell his breath, becauſe they imagined it inſpired them with the gift of prophecy.

On his arrival at Memphis, they conducted him to the temple of Oſiris, wherein were two magnificent ſtalls; one of which was built by Pſammeticus, ſupported by ſtatues, after the manner of the Coloſſus, twelve cubits high; here he continued almoſt always ſhut up, being hardly ever ſeen but by ſtrangers, to whom he was ſhewn in a little meadow joining to the temple. If they at any time led him about the city, he was attended by officers to keep off the croud, and accompanied by young children who ſung his praiſes.

APIUM, in botany, the name of a herb called in Engliſh parſley. See PARSLEY.

APIUM *Paluſtre*, ſmallage. See the article SMALLAGE.

APOBATERION, among the ancients, implied a valedictory or farewel ſpeech, or poem, made by a perſon on his leaving his own country, or ſome other place, where he had been kindly received and entertained.

APOCALYPSE, Revelation, the name of one of the ſacred books of the New Teſtament, containing revelations concerning ſeveral important doctrines of Chriſtianity.

The word is formed from the Greek, *αποκαλυψις*, and derived from *αποκαλυπτω*, to reveal, or diſcover.

This book, according to Irenæus, was written about the year 96 of Chriſt, in the iſland of Patmos, whither St. John had been baniſhed by the emperor Domitian. But Sir Iſaac Newton, with very good reaſon, places the writing this book earlier, viz. in the time of Nero. Some attribute this book to the arch-heretic Cerinthus: but the ancients unanimouſly aſcribed it to John, the ſon of Zebedee, and brother of James. This book has not, at all times, been eſteemed canonical. There were many churches in Greece, as St. Jerom informs us, which did not receive it; neither is it in the catalogue of canonical books, prepared by the council of Laodicea, nor in that of St. Cyril of Jeruſalem: but Juſtin, Irenæus, Origen, Cyprian, Clemens of Alexandria, Tertullian, and all the fathers of the fourth, fifth, and the following centuries, quote the Revelations as a book then acknowledged to be canonical. The Alogians, Marcionites, Cerdonians, and Luther himſelf, rejected this book: but the proteſtants have forſaken Luther in this particular; and Beza has ſtrongly maintained againſt his objections, that the Apocalypſe is authentic and canonical.

The Apocalypſe conſiſts of twenty-two chapters. The three firſt are an inſtruction to the biſhops of the ſeven churches of Aſia Minor. The fifteen following chapters contain the perſecutions which the church was to ſuffer from the Jews, heretics, and Roman emperors. Next, St. John propheſies of the vengeance of God, which he will exerciſe againſt thoſe perſecutors, againſt the Roman empire, and the city of Rome, which he deſcribes under the name of Babylon, the great whore, ſeated upon ſeven hills. In the laſt place, the 19th, 20th, 21ſt, and 22nd chapters, deſcribe the triumph of the church over its enemies, the marriage of the Lamb, and the happineſs of the church triumphant.

It is a part of this prophecy (ſays Sir Iſaac Newton) that it ſhould not be underſtood before the laſt age of the world; and therefore it makes for the credit of the prophecy, that it is not yet underſtood. The folly of interpreters have been to foretel times and things by this prophecy, as if God deſigned to make them prophets. By this raſhneſs they have not only expoſed themſelves, but brought the prophecy alſo into contempt. The deſign of God was much otherwiſe: he gave this and the prophecies of the Old Teſtament, not to gratify men's curioſities, by enabling them to foreknow things; but that, after they were fulfilled, they might be interpreted by the events, and his own providence, not the interpreters, be then manifeſted thereby to the world.

There is already ſo much of the prophecy fulfilled, that as many as will take pains in this ſtudy, may ſee ſufficient inſtances of God's providence. Among the interpreters of the laſt age, there is ſcarce one of note who has not made ſome diſcovery worth knowing; and thence I gather, that God is above opening theſe myſteries.

The apocalypſe of John is written in the ſame ſtile and language with the prophecies of Daniel, and hath the ſame relation to them which they have to one another; ſo that all of them together make but one conſiſtent prophecy, pointing out the various revolutions that ſhould happen, both to the church and to the ſtate; and, at length, the final deſtruction and downfal of the Roman empire. *Newton on Prophecies.*

APOCLYSMA, in pharmacy, the ſame with rob. See the article ROB.

APOCOPE, among grammarians, a figure which cuts off a letter or ſyllable from the end of a word; as *ingeni* for *ingenii.*

The word is Greek, and compounded of *αϖο*, from, and *κοϖτω*, to cut.

APOCRASIARIUS, in antiquity, an officer who delivered the meſſages of the emperor. He was afterwards chancellor, and kept the ſeals.

APOCRUSTICS, in pharmacy, the ſame with repellents. See REPELLENTS.

APOCRYPHA, or APOCRYPHAL *Books*, ſuch books as are not admitted into the canon of Scripture, being either not acknowledged as divine, or ſpurious.

The word is Greek, *αϖοκρυφα*, which is derived from *αϖο*, and *κρυϖτω* to hide or conceal.

When the Jews publiſhed their ſacred books, they only gave the appellations of canonical and divine to ſuch as they then made public; and ſuch as were ſtill retained in their archives they called apocryphal, for no other reaſon, but becauſe they were not public; ſo that they might be really ſacred and divine, though not promulged as ſuch.

Thus, in reſpect of the Bible, all books were called apocryphal which were not inſerted in the Jewiſh canon of Scripture. Voſſius obſerves, that, with regard to the ſacred books, none are to be accounted apocryphal, except ſuch as had neither been admitted into the ſynagogue nor the church, ſo as to be added to the canon, and read in public.

The proteſtants do not only reckon thoſe books to be apocryphal which are eſteemed ſuch in the church of Rome, as the prayer of Manaſſeh king of Judah, the third and fourth book of Eſdras, St. Barnabas's epiſtle, the book of Hermos, the addition at the end of Job, and the 151ſt pſalm; but alſo Tobit, Judith, Eſther, the book of Wiſdom, Jeſus the ſon of Sirach, Baruch the prophet, the Song of the Three Children, the hiſtory of Suſanna, the hiſtory of Bell and the Dragon, and the firſt and ſecond book of Maccabees.

It is not pretended that theſe books were received by the Jews, or ſo much as known to them. None of the writers of the New Teſtament cite or mention them: neither Philo nor Joſephus ſpeak of them. The Chriſtian church was for ſome ages an utter ſtranger to theſe books. Origen, Athanaſius, Hilary, Cyril of Jeruſalem, and all the orthodox writers, who have given catalogues of the canonical books of Scripture, unanimouſly concur in rejecting theſe out of the canon. And for the New Teſtament they are divided in their opinions, whether the Epiſtle to the Hebrews, the Epiſtle of St. James, and the ſecond Epiſtle of St. Peter, the ſecond and third Epiſtles of St. John, the Epiſtle of St. Jude, and the Revelations, are to be acknowledged as canonical or not.

The proteſtants acknowledge ſuch books of Scripture only to be canonical as were ſo eſteemed to be in the firſt ages of the church; ſuch as are cited by the earlieſt writers among the Chriſtians as of divine authority, and after the moſt diligent enquiry were received, and ſo judged to be by the council of Laodicea. The ſeveral epiſtles abovementioned, and the book of Revelations, whatever the ſentiments of ſome particular perſons are or may have been of them, are allowed by all the reformed churches to be parts of the canon of the New Teſtament.

APOCYNUM, dogs-bane, in botany, a genus of plants, the leaves of which are produced oppoſite by pairs upon the branches: the flower conſiſts of one leaf, which is cut into ſeveral ſegments; from its flower-cup ariſes the pointal, which is fixed like a nail in the back part of the flower, and is afterwards changed into a fruit, which is, for the moſt part, compoſed of two capſules, or pods, which open from the baſe to the top, incloſing many ſeeds, which have a long pappous down adhering to them: to this may be added, that the whole plant abounds with a milky juice.

There are ſeveral ſorts of this plant cultivated in the curious gardens of plants, ſome of which are very beautiful, and deſerve a place in every good garden. *Miller's Dict.*

APODICTICAL *Argument*, or *Syllogiſm*, implies a clear convincing proof of a propoſition.

The word is formed from the Greek, αϖοδεικνυμι, to demonſtrate.

APODOSIS, in rhetoric, the ſame with axioſis. See Axiosis.

APODYTERIUM, in the ancient baths, the apartment where perſons dreſſed and undreſſed.

The word is Greek, αϖοδυτηριον, and derived from αϖοδυω, to undreſs.

APOGEE, *Apogæum*, in aſtronomy, that point in the orbit of a planet, which is at the greateſt diſtance from the earth.

The word is Greek, compounded of αϖο, from, and γη, the earth.

The apogee of the ſun is that point of the earth's orbit which is at the greateſt diſtance from the ſun; and conſequently the ſun's apogee, and the earth's aphelion, are one and the ſame point.

The quantity of the motion of the apogee may be found by comparing two obſervations thereof made at a great diſtance of time, converting the difference into minutes, and dividing it by the number of years elapſed between the two obſervations. The quotient gives the annual motion of the apogee. Thus, from an obſervation made by Hipparchus, in the year before Chriſt, 140, whereby the ſun's apogee was found 5°, 30′, of Gemini; and another made by Ricciolus, in the year of Chriſt 1646, wherein it was found 7°, 26′, of Cancer; the annual motion of the apogee is found to be 1′, 4″. De la Hire, in Tab. Aſtron. p. 15, makes the apogee of the ſun to be in 8°, 7′, 30″, of ♋, and its annual motion 1′, 2″.

Apogee *of the Moon*. See the article Moon.

Apogee *of the Equant* is its fartheſt diſtance from the earth, or that point where the circumference of the equant is interſected by the line of the apſides, in the remoteſt part of the diameter.

The mean apogee of the epicycle is a point where the epicycle is cut above, by a right line drawn from its center, to the center of the equant, or the point of the epicycle moſt remote from the earth.

APOLLINARIAN *Games*, in antiquity, an appellation given to certain theatrical entertainments annually performed in honour of Apollo.

APOLLINARIANS, or Apollinarists, in eccleſiaſtical hiſtory, a ſect of heretics, ſo called from Apollinaris of Laodicea, their leader, who affirmed that Chriſt had neither a rational human ſoul, nor a true body; and that the ſouls of men were propagated by other ſouls, as well as their bodies.

APOLLONIA, in antiquity, an annual feſtival celebrated by the Ægialians, in honour of Apollo.

APOLLONIAN *Hyperbola* and *Parabola*. See the articles Hyperbola and Parabola.

APOLOGUE, an ingenious method of conveying inſtruction, by means of a feigned relation, called a moral fable.

The only difference between a parable and an apologue conſiſts in this, that the former being drawn from what paſſes among mankind, requires probability in the narration; whereas the apologue being generally taken from the ſuppoſed actions of brutes, or even things inanimate, is not confined by ſuch ſtrict rules of probability.

APOLOGY, a defence or excuſe for ſome perſon, action, or the like, either by words or writing.

The word is Greek, αϖολογια, and derived from ἀϖολογεομαι, to defend or excuſe.

APONEUROSIS, in anatomy, the ſpreading or expanſion of a nerve or tendon, in the manner of a membrane.

The word is Greek, and compounded of αϖο, from; and νευρον, a nerve.

APOPHYGE, in architecture, the convex part, or ring, of a column, lying either above or below the flat member. It was originally nothing more than the ferril or ring, fixed on the extremity of a wooden pillar to prevent its ſplitting; and was afterwards imitated in ſtone.

The word is Greek, and properly ſignifies *flight*; and hence ſome architects call it the ſpring of the column.

APOPHYSIS, in anatomy, a protuberance of a bone, or a part jutting out beyond the reſt.

APOPLECTIC, ſomething that relates, or belongs to, an apoplexy.

APOPLEXY, among phyſicians, any diſorder which inſtantaneouſly deprives a man of life, who a few minutes before was, or at leaſt ſeemed to be, in perfect health; but it is uſually confined to ſuch ſudden diſorders cauſed by affections of the brain.

The word is derived from the Greek, αποπληττω, to ſtrike ſuddenly.

In an apoplexy the patient is ſuddenly deprived of the exerciſe of all the ſenſes, both external and internal, and of voluntary motion, whilſt the pulſe, which is generally ſtrong, remains, together with a laborious and deep reſpiration, attended with a conſiderable elevation of the breaſt, with a ſtertor, and the appearance of profound and perpetual ſleep.

A multitude of the moſt accurate obſervations have made it appear, that this diſorder ariſes from whatever cauſe is capable of preventing, either totally or in part, the influx of the nervous fluid, ſecreted, in the cerebrum, to the organs of ſenſe and voluntary motion, and the reflux of the ſame fluid from the abovementioned organs to the common ſenſory in the brain; whilſt the progreſs, and perhaps the return, of the fluid, ſupplied by the cerebellum, to and from the heart, and organs of reſpiration, is preſerved in a degree ſufficient to ſupport, in ſome meaſure, their functions.

All theſe cauſes, as obſerved and delivered by authors, may, for the greater perſpicuity, be reduced to claſſes; in the firſt of which may be reckoned,

1. The natural make of the body: thus, when the head is naturally large, the neck ſhort, and, as it ſometimes happens, conſiſting only of ſix vertebræ, whereas there ought to be ſeven, this ſtructure diſpoſes to an apoplexy, as it favours the congeſtion of blood and humours in the head. Thus alſo, if the body is corpulent and fat, the capillary arteries in general will be ſubject to compreſſion; and, in conſequence thereof, a greater quantity of blood and humours will flow into the veſſels which convey them to the brain. Thus alſo a plethoric habit, and a redundance of pituitous humours in the blood, lay a foundation for the ſtagnation of the juices, and a ſubſequent rupture of the veſſels in the brain.

2. To the ſecond claſs belong all thoſe cauſes which induce ſuch a change in the blood, lymph, and nervous fluid, as to render them incapable of circulating freely through their reſpective veſſels in the brain. Amongſt theſe are,

Polypous concretions in the carotid or vertebral arteries, whether formed originally about the heart, or within the cranium; which are diſcovered by a palpitation of the heart, an unequal pulſe, a vertigo, and temporary loſs of ſight, often recurring, and which are increaſed by motion or heat.

3. To the third claſs belongs whatever compreſſes the arteries themſelves, or the nervous veſſels of the brain, ſo as to prevent a free circulation of their reſpective fluids through them.

People who are plethoric, that is, full of blood, and bloated with bad humours, are much ſubject to this ſpecies of apoplexy; eſpecially if extraordinary motion or heat increaſe the velocity of the circulation. Hence it is apparent that the diſorder muſt be promoted in ſuch conſtitutions by high feeding and ſpirituous liquors; medicines which are acrid, and excite the motion of the blood, ſuch as cardiacs, volatiles, and emetics; by exceſſive heat and motion; and by intenſeneſs of thought, eſpecially if long continued, and frequently repeated, becauſe this determines a more copious flux of humours towards the brain.

4. To the fourth claſs belongs all thoſe cauſes, which, by any means, ſo diſſolve the texture of the arteries, veins, or lymphatic ducts, belonging to the internal part of the cerebrum, as to cauſe an extravaſation of their reſpective fluids, which then preſs upon and injure the medullary origin of the nerves of the cerebrum. Such, for example, are an acrimonious ſerum in hydropic and leucophlegmatic caſes; a redundance of blood in a plethora; an atrabiliarious acrimony prevalent in melancholy, ſcorbutic, and arthritic conſtitutions, which frequently produces an apoplexy, and uſually operates betwixt the fortieth and ſixtieth years of life. Now, all theſe may remain latent in the conſtitution for ſome time; but, upon being excited by adequate cauſes, they are frequently productive of a ſudden apoplexy; which may be foreſeen by comparing the materials ſubſiſting in the conſtitution with the cauſes capable of exciting them to action, which are principally violent affections of the mind, and intenſe ſtudies; to which, perhaps, imprudent and exceſſive venery may be added.

5. Some ſorts of poiſons, which are ſuddenly deleterious, may be ranked in the fifth claſs; but theſe may be either reduced to the ſecond, third, or fourth; or may be more properly ſaid to act upon the lungs than the brain. Amongſt theſe are the fumes of mineral ſulphurs, of charcoal, and that gas ſylveſtris, or incoercible ſpirit, which exhales from vegetable juices during fermentation.

The anatomical inſpection of bodies which have died of apoplexies, and the hiſtorical obſervation of ſuch circumſtances as occur in the treatment of ſuch caſes, furniſh us with a knowledge of theſe cauſes; and a due reflection upon theſe naturally leads us to a diſtribution of them into the preceding claſſes, which are admirably adapted to the inveſtigation of the beſt methods of cure.

As to the cure and prevention of an apoplexy, no univerſal rules can be laid down; for as the prediſpoſing and exciting cauſes, together with the parts principally affected, are various, the method of relief muſt alſo vary; and muſt be attempted before the diſorder grows inveterate, otherwiſe it will be difficult to do it with ſucceſs.

If, therefore, an apoplexy, from a glutinous, inert cold cauſe, is foreſeen from the ſigns above ſpecified, the intentions muſt be directed, firſt, to avert the preſſure of the glutinous juices from the head.

Secondly, to attenuate the glutinous viſcidity in the brain, and in the whole habit.

The preſſure on the veſſels of the brain are to be diminiſhed,

Firſt, by a derivation of the humours to other, and theſe oppoſite parts.

Secondly, by univerſal evacuations.

A derivation of the humours is effected by vapours, fomentations, and baths, applied to particular parts, by which it is intended the humours ſhould be invited; by ſuction with cupping-glaſſes, by ſinapiſms and veſicatories, among which cantharides are of great importance, as they both invite the humours to the part where they are applied, and attenuate at the ſame time; by cauſtics, iſſues, ſetons, and frictions; by ligatures made upon the large veins of the feet, legs, and thighs. To theſe may be added collutions, gargariſms, and maſticatories, which excite a diſcharge of ſaliva, and apophlegmatiſms applied to the mouth, fauces, and noſe. *Boerhaave.*

APOSIOPESIS, in rhetoric, implies the ſuppreſſing, or omitting to relate part of the ſubject.

The word is Greek, and derived from αποσιωϖαω, to keep ſilence.

APOSTACY, the act of abandoning the true religion.

APOSTHUME, in ſurgery, the ſame with abſceſs. See the article ABSCESS.

APOSTIL, a marginal note, or remark in the margin of a work.

APOSTLE, a meſſenger ſent by ſome perſon on a buſineſs of importance; and hence the word is applied by way of eminence to imply one of the twelve diſciples commiſſioned by Chriſt to preach the Goſpel.

The word is formed from the Greek, αποϛολος, and derived from αποϛελλω, to ſend on a meſſage.

There are various conjectures with regard to the reaſon which induced our Saviour to make choice of twelve apoſtles; but the moſt probable is, that he did it in alluſion to the twelve patriarchs, as the founders of their ſeveral tribes; or to the twelve chief heads or rulers of thoſe tribes, of which the body of the Jewiſh nation conſiſted.

APOSTOLIC, or APOSTOLICAL, ſomething connected with, or derived from, the apoſtles.

APOSTOLICS, an early ſect of Chriſtians, who called themſelves by this name from a vain pretence of being the only men who led their lives in imitation, and after the example of the apoſtles. They condemned marriage, and pretended to have all things in common.

APOSTROPHE, in rhetoric, a figure by which the orator, in a vehement commotion, turns himſelf on all ſides, and applies himſelf to the living and the dead; to angels and to men; to inanimate objects, rocks, groves, ſtreams, &c. Thus Adam, in Milton's Paradiſe Loſt,

> O woods, O fountains, hillocks, dales, and bow'rs,
> With other echo, &c.

The word is Greek, and compounded of απο, from, and ϛρεφω, to turn.

APOSTROPHE, in grammar, implies a mark placed over a letter to ſhew that a vowel is cut off; as *call'd* for *called*, &c.

APOTACTITES, in eccleſiaſtical hiſtory, the ſame with apoſtolics. See APOSTOLICS.

APOTHECARY, a perſon who practiſes the art of pharmacy.

The word is formed from the Greek, αϖοθηκη, a ſhop.

This is a very genteel buſineſs, and has been in very great vogue of late years, there being, as has been computed, upwards of 1000 in and about London. There are, in this profeſſion, various degrees, as to employ and extent.

Some do little elſe but make up medicines according to the preſcription of the diſpenſary (compiled by the order of the College of Phyſicians, for their direction) and of thoſe of particular phyſicians, beſides viſiting their patients.

Others not only prepare almoſt all kinds of medicines, as well galenical as chemical, but likewiſe deal in drugs, with all which they ſupply their brethren in trade; and ſo become a ſort of wholeſale dealers, as well as apothecaries.

Others, again, practiſe ſurgery, manmidwifery, and many times even officiate as phyſicians, eſpecially in the country; and often become men of very large practice, and eminent in their way. There is another branch alſo many of them fall into, which is that of curing lunatics, &c.

A youth intended for this profeſſion ſhould be a pretty good ſcholar, and have a tolerable knowledge in the Latin tongue at leaſt, that he may be the better able, in due time, to read ſome of the beſt authors who have wrote upon the ſubjects of botany, pharmacy, anatomy, and medicine; though it muſt be owned there are, at preſent, almoſt innumerable helps in our mother-tongue.

In London, they are one of the city companies, and were firſt incorporated with the grocers in the year 1606, in the reign of king James I. but not alone till 1617.

They have a hall, where there are two fine elaboratories, out of which all the ſurgeons cheſts are ſupplied with medicines for the uſe of the Britiſh navy.

In the year 1712, the 10th of queen Anne, an act paſſed for reviving and continuing ſeveral acts therein mentioned, one whereof was for exempting the apothecaries from ſerving the offices of conſtables and ſcavengers, and other pariſh and ward offices, and from ſerving upon juries: which act was made perpetual in the 9th year of king George the Firſt.

The apothecaries in England are obliged to make up their medicines according to the formulas preſcribed in the Diſpenſatory of the College of Phyſicians, and are under an obligation to have the medicines there enumerated always ready in their ſhops; and their ſhops are liable to be viſited by the cenſors of the college, who have it in their power to deſtroy ſuch medicines as they judge not to be good.

The apothecaries of Paris make but one corporation with the merchant-grocers, which is the ſecond of the ſix corporations of merchants.

By a regulation of the 15th of October, 1631, all the apothecaries of Paris are prohibited to give any medicine to patients, unleſs by the order, and with the advice of a regular-bred phyſician, or of a perſon of the faculty; nor are they to make up any preſcription, given, or drawn up, by any perſon ſtiling himſelf an empiric phyſician, or operator.

Among the good regulations made in Denmark, that which the apothecaries are obliged to obſerve is reckoned one of the beſt; for no perſon can have leave to follow that profeſſion, unleſs he be approved of by the college of phyſicians, and confirmed by the king himſelf. There are but two apothecaries allowed for the city of Copenhagen, and but one in every other conſiderable town. The magiſtrates, attended by the doctors of phyſic, viſit their ſhops and drugs twice or thrice a year, and thoſe drugs that are either ſtale or bad are ſeized, and publicly thrown upon a dung-hill without the city; and this is a ſtain upon the character of ſuch an apothecary, that is ſcarce ever wiped off. The price of all drugs is fixed, ſo that one may, without fear of being impoſed upon, ſend even a child for any drug to an apothecary's ſhop, where nothing is ſold but what is very good, and at a reaſonable price. All drugs are ſold for ready money, and yet the apothecaries are obliged to regiſter in a book what they ſell, to whom, and by what phyſician's preſcription: ſo that there ſeldom happens any accident by poiſon, either accidentally, or with deſign; and if any ſuch thing happens, it is eaſily found out, and quickly puniſhed.

APOTHEOSIS, in antiquity, a heathen ceremony, whereby their emperors and great men were placed among the gods.

The word is Greek, and compounded of *απο*, and ϑεος, god.

It was one of the doctrines of Pythagoras, which he had borrowed from the Chaldees, that virtuous perſons, after their death, were raiſed into the order of the gods.

And hence the ancients deified all the inventors of things uſeful to mankind, and who had done any important ſervice to the commonwealth. Tiberius propoſed to the Roman ſenate the apotheoſis of Jeſus Chriſt, as is related by Euſebius, Tertullian, and St. Chryſoſtom. Juvenal rallying the frequent apotheoſes, introduces poor Atlas complaining that he was ready to ſink under the prodigious burthen of ſo many new gods as were almoſt every day added to the heavens.

Seneca ridicules the apotheoſis of Claudius with admirable humour. Herodian, lib. 4, in ſpeaking of the apotheoſis of Severus, gives us a very curious deſcription of the ceremonies uſed in the apotheoſes of the Roman emperors.—After the body of the deceaſed emperor, ſays he, had been burnt with the uſual ſolemnities, they placed an image of wax, perfectly like him, but of a ſickly aſpect, on a large bed of ivory, covered with cloth of gold, in the veſtibule of the palace. During the greater part of the day the ſenate ſat ranged on the left ſide of the bed, dreſſed in robes of mourning; the ladies of the firſt rank ſitting on the right ſide, in plain and white robes, without any ornaments. This laſted for ſeven days ſucceſſively, during which the phyſicians came from time to time to viſit the ſick, always making their report that he grew worſe and worſe; till at length they publiſhed that he was dead.

Upon this, the young ſenators and Roman knights took the bed of ſtate upon their ſhoulders, carrying it through the via ſacra to the old forum, where the magiſtrates uſed to diveſt themſelves of their offices. There they ſet it down between two kinds of amphitheatres, in the one of which were the youth, and in the other the maidens of the firſt families in Rome, ſinging hymns ſet to ſolemn airs in praiſe of the deceaſed. Theſe hymns being ended, the bed was carried out of the city to the Campus Martius, in the middle whereof was erected a kind of ſquare pavilion, the inſide of which was full of combuſtible matter, and the outſide hung with cloth of gold, and adorned with figures of ivory, and various paintings. Over this edifice were ſeveral others, like the firſt in form and decoration, but leſs; always diminiſhing and growing leſs towards the top. On the ſecond of theſe was placed the bed of ſtate, with a great quantity of aromatic perfumes, and odoriferous fruits and herbs were ſcattered around; after which the knights made a proceſſion or cavalcade in ſolemn meaſures round the pile; ſeveral chariots alſo ran round it, thoſe who conducted them being dreſſed in purple robes, and bearing images of the greateſt Roman emperors and generals.

As ſoon as this ceremony was ended, the new emperor came to the catafalco or pile, with a torch in his hand; and at the ſame time fire was ſet to it on all ſides, the ſpices and other combuſtibles kindling all at once.

While this was doing, they let fly from the top of the building an eagle, which, mounting into the air with a firebrand, carried with it, as they believed, the ſoul of the dead emperor into heaven; and he was accordingly ranked among the gods. For this reaſon the medals on which apotheoſes are repreſented, have generally either an altar with fire upon it, or an eagle taking its flight towards heaven.

APOTOME, in mathematics, the remainder or difference of two incommenſurable quantities.

The word is derived from the Greek verb, *αϖοτεμνω*, to cut off.

Euclid calls an apotome a line BC (plate XV. *fig.* 3.) which is the difference between a rational line AC, and a line AB only commenſurable in power to the whole line AC, and may be expreſſed thus, ſuppoſing ($AC=a$, and $AB=b$) viz. $a-\sqrt{b}$, or in numbers $2-\sqrt{3}$, a being 2, and b, 3. Hence the difference between the ſide of a ſquare and its diagonal will be an apotome; for if s repreſents the ſide of the ſquare, $\sqrt{2ss}$ will repreſent the diagonal, and conſequently $\sqrt{2}\times s-s$, or $\overline{\sqrt{2}-1}\times s$ will be the difference between two quantities, one a rational quantity, and the other an irrational one, that are only commenſurable in power. It follows alſo that the difference between the ſide $AC=2$ of an equilateral triangle ABC, and the perpendicular $BD=\sqrt{3}$ will be an apotome, viz. $=2-\sqrt{3}$.

The doctrine of apotomes is a very uſeful ſubject; it ſerves to ſhew the poſſibility or impoſſibility of the quadratures of curved-line figures, and illluſtrates the lineal ſolutions of Diophantus's problems, and others of the like kind. Euclid, in his Elements, makes uſe of this method to ſhew the nature of the five regular bodies, which by Plato and his ſect (of which Euclid's was one) were held in great eſteem. And in the laſt age, Kepler (in his *Myſteria Coſmographica*) would have the number of the planets and the magnitudes of the ſyſtems of the world to ariſe from theſe bodies.

APOZEM, in pharmacy, the ſame with decoction. See DECOCTION.

APPANAGE. See the article APANAGE.

APPARATOR. See APPARITOR.

APPARATUS, a term uſed to denote a complete ſet of inſtruments, or other utenſils, belonging to any artiſt or machine: thus we ſay a ſurgeon's apparatus, a chemiſt's apparatus; the apparatus of the air-pump, microſcope, &c.

APPARENT, in a general ſenſe, implies whatever is evident to the eye or underſtanding.

APPARENT *Altitude*. See the article ALTITUDE.

APPARENT *Conjunction*, in aſtronomy, is when the right line connecting the centers of two planets, &c.

does not paſs through the center of the earth, but thro' the eye of a ſpectator ſituated on its ſurface.

Apparent, or *ſenſible Horizon*, is that great circle which limits our ſight, or the place where the heavens and the earth ſeem to meet.

Apparent *Magnitude* of an object, is the magnitude thereof, ſuch as it appears to the eye.

The apparent or ſeeming magnitude is meaſured by the optic angle.

Thus the apparent magnitude of an object is ſaid to be ſo many degrees as the optic or viſual angle ſubtends. Let D C (plate XV. *fig.* 4.) be an object viewed by the eye at A and B, then the angle C A D is the apparent magnitude of that object ſeen at A; and the angle C B D, its apparent magnitude, when viewed at B.

All things appear the leſs, the more remote they are; and it is found by experience, when their diſtance becomes ſo great that the apparent magnitude is no more than an angle of one ſecond, they will be ſo ſmall as to appear but like a point, and become inviſible.

Apparent *Diameter*, in aſtronomy, is the angle under which we ſee the ſun, moon, and ſtars; as when the ſun S (plate XV. *fig.* 5.) appears under the angle D O E, this angle is the apparent diameter.

The beſt way of finding the apparent diameters of the celeſtial luminaries is by a micrometer fixed in the focus of a teleſcope. See Micrometer.

The apparent diameter of the ſun may be obtained by taking the meridian altitudes of his upper and lower limbs with a good quadrant and teleſcope fitted to it, and afterwards taking their difference, which will be his apparent diameter ſeen from the earth. Another way is by erecting two perpendicular threads over the meridian line, and, while the eye is at reſt, obſerving the ſun's paſſage over the meridian; and noting the inſtant that the limb of the ſun comes to the threads, by an accurate time-keeper or clock, and the inſtant that its oppoſite limb leaves them, the difference is the time wherein the diameter of the ſun is paſſing over the meridian: which if the ſun be in the equator, this time turned into minutes of a degree, will be the angle under which the ſun appears: but if the ſun be out of the equator, the arch found is part of that parallel circle the ſun moves in, which muſt be turned into minutes, &c. of the equator.

The apparent diameter of the ſun is obſerved to be leaſt when he is in Cancer, and greateſt when in Capricorn.

In the moon there is a two-fold increaſe and decreaſe of the apparent diameter, the one when ſhe is in conjunction with the ſun, and the other when in her quadratures.

The greateſt apparent diameter of the ſun, according to Caſſini, is 32′, 10″, and the leaſt 31′, 38″—According to De la Hire, the greateſt is 32′, 43″, and the leaſt 31′, 38″.—The greateſt apparent diameter of the moon, according to Kepler, is 32′, 44″, and the leaſt 30′, 00″. And according to De la Hire, the one is 33′, 30″, and the other 29′, 30″. See Sun and Moon.

The apparent diameter of Saturn's ring, according to Huygens, is 1′, 8″, when leaſt.

The apparent diameters of the other planets ſee under the article Diameter.

Apparent *Diſtance* is that diſtance we judge an object to be from us when ſeen afar off, being generally very different from the true diſtance, becauſe we are apt to think that all very remote objects, whoſe parts cannot well be diſtinguiſhed, and which have no other object in view near them, to be at the ſame diſtance from us, tho' perhaps they may be thouſands of miles, as in the caſe of the ſun and moon.

Apparent *Motion*, *Time*, &c. See Motion, Time, &c.

Apparent *Place of any Object*, in optics, is that wherein it appears when ſeen through one or more glaſſes. See Lens.

Apparent *Place of the Image of an Object*, in catoptrics, is that which the image of an object, made by the reflection of a ſpeculum, appears to be in.

Apparent *Place of a Planet*, in aſtronomy, is that point upon the ſurface of the ſphere where we ſee the center of the ſun, moon, or ſtars, from the ſurface of the earth.

APPARITION, in a general ſenſe, implies ſimply the appearance of any object.

Apparition, in aſtronomy, ſignifies a ſtar, or other heavenly object becoming viſible, which before was below the horizon.

Circle of perpetual Apparition, in aſtronomy, is a great circle of the ſphere, whoſe plane is perpendicular to a right line drawn from the center of the ſun to that of the earth; this circle is the boundary of the enlightened hemiſphere of the earth, in the different points of its orbit.

Circle of perpetual Apparition, in geography, is a ſmall circle of the ſphere deſcribed about the pole as a center, and touching the northern point of the horizon in north latitude, and the ſouth point in ſouth latitude. All ſtars included in this circle never ſet, but are always viſible above the horizon.

APPARITOR, among the Romans, a general term to comprehend all attendants of judges and magiſtrates appointed to receive and execute their orders. Apparitor, with us, is a meſſenger that ſerves the proceſs of a ſpiritual court, or a beadle in an univerſity, who carries the mace.

APPAUMEE, in heraldry, denotes one hand extended with the full palm appearing, and the thumb and fingers at full length.

APPEAL, in law, the removal of a cauſe from an inferior to a ſuperior court or judge, when a perſon thinks himſelf aggrieved by the ſentence of the inferior judge. Appeals lie from all the ordinary courts of juſtice to the houſe of lords. In eccleſiaſtical caſes, if an appeal is brought before a biſhop, it may be removed to the archbiſhop; if before an archdeacon, to the court of arches; and thence to the archbiſhop; and from the archbiſhop's court to the king in chancery.

Appeal, in common law, is taken for the accuſation of a murderer by a perſon who had intereſt in the party killed, or of a felon by an accomplice. It is proſecuted either by writ or by bill: by writ, when a writ is purchaſed out of the chancery by one perſon againſt another, commanding him to appeal ſome third perſon of felony, and to find pledges for doing it effectually; by bill, when the perſon himſelf gives in his accuſation in writing, offering to undergo the burden of appealing the perſon therein named.

APPEARANCE, in a general ſenſe, the exterior ſurface of a thing, or that which immediately ſtrikes the ſenſes.

Appearance, in law, ſignifies a defendant's filing a common or ſpecial bill, on any proceſs iſſued out of a court of judicature. In actions by original, appearances are entered with the filazer of the county; and by bill, with the prothonotary.

In perſpective, appearance is the projection of a figure or body on the perſpective plane. In optics, direct appearance is the ſight of any object by direct rays, without refraction or reflection.

In aſtronomy, it ſignifies the ſame as phænomena or phaſes; and in phyſiology, the ſame as phaſmata.

APPELLANT, in a general ſenſe, one who appeals. See the article Appeal.

APPELLANTS, in church hiſtory, an appellation given to ſuch of the Roman catholic clergy as appeal from the conſtitution Unigenitus to a general council.

APPELLATIVE, in grammar, a noun which is applicable to a whole ſpecies or kind, as man, horſe, in contradiſtinction to a proper noun. See Noun.

APPELLEE, among lawyers, the perſon againſt whom an appeal is brought. See the article Appeal.

APPENDANT, in law, any thing that is inheritable belonging to ſome more worthy inheritance, as an advowſon, common, or court, may be appendant to a manor, land to an office, &c. but land cannot be appendant to land, for both are corporeal inheritances, and one thing corporeal cannot be appendant to another.

APPENDICULAR *Vermiformis*, in anatomy, a name by which ſome call the cœcum. See the article Coecum.

APPENDIX, in literature, a treatiſe added at the end of a work, to render it more complete. See the article SUPPLEMENT.

APPENDIX, in anatomy, the ſame with epiphyſis. See EPIPHYSIS.

APPETITE, *Appetitus*, in a general ſenſe, the deſire of enjoying ſome object, ſuppoſed to be conducive to our happineſs. When this inclination is guided by reaſon, and proportioned to the intrinſic value of the object, it is called rational appetite; as, on the other hand, it is denominated ſenſitive appetite, when we have only a blind propenſity to a thing, without determinate ideas of the good qualities for which we deſire it.

APPETITE, in medicine, a certain painful or uneaſy ſenſation, always accompanied with a deſire to eat or drink.

An exceſſive appetite is called by phyſicians bulimy, or fames canina; a defect or loſs of it, anorexy; and that after things improper for food, pica. See the articles BULIMY, ANOREXY, &c.

APPLE, a well known fruit, of a roundiſh figure, of conſiderable uſe both as a food, a remedy, and likewiſe yielding cyder.

The apple is compoſed of four diſtinct parts, viz. the peel, the parenchyma, the branchery, and the core.

The peel or ſkin is only a dilatation of the outermoſt ſkin or rind of the bark of the branch on which it grew.

The parenchyma or pulp, as tender and delicious as it is found, is only a dilatation, or, as Dr. Grew calls it, a ſwelſth, or ſuperbience of the inner part of the bark of the branch.

This appears not only from the viſible continuation of the bark from the one, through the pedicle or ſtalk to the other, but alſo from the ſtructure common to both, as being both compoſed of bladders; with this only difference, that whereas, in the bark, the veſiculæ are ſpherical, and very ſmall, ſcarce exceeding one ſixteenth part of an inch in diameter; in the pulp they are oblong, and very large, generally meaſuring one-third of an inch in length; but all uniformly ſtretched out by the arching of the veſſels from the core towards the circumference of the apple.

The branchery or veſſels are only ramifications of the woody part of the branch ſent throughout all the parts of the parenchyma, the greater branches being made to communicate with each other by inoſculations of the leſs. The main branches are uſually twenty; ten of them diſtributed through the parenchyma, moſt of which march themſelves towards the cork or ſtool of the flower, the other ten, running from the ſtalk in a directer line, at laſt meet the former at the cork, and are there inoſculated with them. To theſe branches the coats of the kernels are faſtened. Moſt of the branches were originally extended beyond the fruit, and inſerted into the flower for the due growth thereof; but when the fruit afterwards grew to a head, and thus intercepted the aliment before ſent to the flower, this latter being ſtarved and falling off, the ſervice of the ſaid branches became wholly appropriated to the fruit, fifteen to the pulp, and five to the ſeed. The apple core is originally from the pith of the branch; the ſap of which finding room enough in the parenchyma, through which to diffuſe itſelf, quits the pith, which by this means hardens into a core.

All the ſorts of apples are propagated by grafting or budding upon the ſtocks of the ſame kind; for they will not take upon any other ſort of fruit-tree. In the nurſeries there are three ſorts of ſtocks generally uſed to graft apples upon: the firſt are called free ſtocks; theſe are raiſed from the kernels of all ſorts of apples indifferently; and theſe are alſo termed crab-ſtocks; for all thoſe trees which are produced from the ſeeds before they are grafted, are termed crabs without any diſtinction: but, as I before obſerved, I ſhould always prefer ſuch ſtocks as are raiſed from the kernels of crabs, where they are preſſed from verjuice; and I find ſeveral of the old writers on this ſubject of the ſame mind. Mr. Auſtin, who wrote an hundred years ago, ſays, the ſtock which he accounts beſt for apple grafts, is the crab; which is better than ſweeter apples, and will make fruits more ſtrong and hardy to endure froſts; and it is very certain, that, by frequently grafting ſome ſorts of apples upon free-ſtocks, the fruits have been rendered *leſs* firm and poignant, and of ſhorter duration.

The ſecond ſort of ſtock is the Dutch creeper: theſe are deſigned to ſtint the growth of the trees, and keep them within compaſs for dwarfs or eſpaliers.

The third ſort is the paradiſe apple, which is a very low ſhrub, ſo only proper for trees which are kept in pots by way of curioſity; for theſe do not continue long.

Some perſons have made uſe of codlin-ſtocks for grafting of apples, in order to ſtint their growth: but as theſe are commonly propagated by ſuckers, I would by no means adviſe the uſe of them; nor would I chooſe to raiſe the codlin-trees from ſuckers, but rather graft them upon crab-ſtocks; which will cauſe the fruit to be finer, laſt longer, and have a ſharper flavour: and theſe trees will laſt much longer ſound, and never put out ſuckers, as the codlins always do; which, if not conſtantly taken off, will weaken the trees, and cauſe them to canker; and it is not only from the root, but from the knots of their ſtems there are generally a great number of ſtrong ſhoots produced, which fill the trees with uſeleſs ſhoots, and render them unſightly, and the fruit ſmall and crumpled.

The method of raiſing ſtocks from the kernels of crabs or apples is, to procure them where they are preſſed for verjuice or cyder; and, after they are cleared of the pulp, they may be ſown upon a bed of light earth, covering them over about half an inch thick with the ſame light earth: theſe may be ſown in November or December, where the ground is dry; but in wet ground, it will be better to defer it till February; but then the ſeeds ſhould be preſerved in dry ſand, and kept out of the reach of vermin; for if mice or rats can get to them, they will devour the ſeeds: there ſhould alſo be care taken of the ſeeds when they are ſown, to protect them from theſe vermin, by ſetting of traps to take them, &c. In the ſpring, when the plants begin to appear, they muſt be carefully weeded; and if the ſeaſon ſhould prove dry, it will be of great ſervice to water them two or three times a week; and, during the ſummer, they muſt be conſtantly kept clear from weeds; which, if ſuffered to grow, will ſoon over-top the plants, and ſpoil their growth: if theſe thrive well, they will be fit to tranſplant into the nurſery the October following; at which time the ground ſhould be carefully digged, and cleanſed from the roots of all bad weeds: then the ſtocks ſhould be planted in rows three feet aſunder, and the plants one foot diſtance in the rows, cloſing the earth pretty faſt to their roots: when the ſtocks are tranſplanted out of the ſeed-bed, the firſt autumn after ſowing, they need not be headed; but, where they are inclined to ſhoot downward, the top-root muſt be ſhortened, in order to force out horizontal roots. If the ground is pretty good in which the ſtocks are planted, and the weeds conſtantly cleared away, the ſtocks will make great progreſs; ſo that thoſe which are intended for dwarfs, may be grafted the ſpring twelvemonth after they are planted out of the ſeed-beds: but thoſe which are deſigned for ſtandards will require two years more growth, before they will be fit to graft; by which time they will be upwards of ſix feet high. The other neceſſary work to be obſerved in the culture of theſe trees, while they remain in the nurſery, will be enumerated under that article. See NURSERY. *Miller's Gard. Dict.*

APPLICATION, in a general ſenſe, implies the laying two things together, in order to diſcover their agreement.

APPLICATION *of one Science to another*, ſignifies the uſe we make of applying the principles and truths belonging to one ſcience, to complete or advance another.

APPLICATION *of Algebra to Geometry*, implies the ſolving geometrical problems by the aſſiſtance of algebra.

As the line, the ſurface, and the ſolid, objects of geometry are commenſurable magnitudes, it is very natural to think that, as algebra and analyſis were wholly employed in the calculation of magnitudes, and diſcovering unknown quantities from proper data, they might be applied with very great advantage to geometry. But however natural and eaſy this application may appear, Des Cartes was the firſt that ever knew it, though algebra had been very greatly improved by ſeveral perſons, eſpecially Vieta.

Des Cartes firſt taught us to expreſs the nature of curves by equations, to reſolve geometrical problems by theſe curves, and, in ſhort, to demonſtrate theorems in geometry by the help of algebraical calculation, when it would be too laborious to demonſtrate them by the common methods. See the articles CURVE and *Conſtruction of* EQUATIONS.

APPLICATION *of Geometry to Algebra.*—The application of geometry to algebra is not ſo common as the application of algebra to geometry, but ſometimes takes place: for as we repreſent geometrical lines by equations, ſo we may repreſent numerical quantities, expreſſed by algebraical ſymbols, by geometrical lines; and by this means ſometimes diſcover a more eaſy method of demonſtration and ſolution.

APPLICATION *of Geometry and Algebra to Mechanics.*—This is founded on the ſame principles as the application of algebra to geometry. It conſiſts chiefly in repreſenting the curves which bodies deſcribe in their motion by equations, in determining the equation between the ſpaces which bodies generate, (when acted upon by any powers whatever) and the time they take to paſs through theſe ſpaces, &c. We cannot indeed compare two things of a different nature together, ſuch as ſpace and time; but we may compare the proportion of time with the parts of ſpace paſſed over. Time in its nature flows uniformly, and mechanics imply the ſame uniformity.

Further, without knowing time in itſelf, and having any exact meaſure of it, we cannot repreſent it more clearly, with reſpect to its parts, than by the parts of an infinite right line. Now the proportion between the parts of ſuch a body, moved in whatever manner, may always be expreſſed by an equation. Let us ſuppoſe a curve, the abſciſſæ of which repreſent the portions of time paſt ſince the beginning of the motion, the correſponding ordinates denoting the ſpaces paſſed through during theſe portions of time. The equation of this curve will expreſs, not only the proportion of the time to the ſpace, but, if we may ſpeak ſo, the proportion of the proportion that the parts of time have to their unity, to that which the parts of ſpace paſſed through have to theirs; for the equation of a curve may be conſidered either as expreſſing the proportion of the ordinates to the abſciſſa, or as the equation between the proportion that the ordinates have to their unity, and that which the correſponding abſciſſa have to theirs.

It is evident then, that by the bare application of geometry and calculation, we may account for the general properties of motion, varied by any law whatever, without the help of any other principle. In the article ACCELERATED *Motion*, may be ſeen an example of geometry applied to mechaniſm; the time of the deſcent of a gravitating body is there repreſented by the perpendicular of a triangle, the velocity by the baſe, and the ſpaces paſſed through by the area of the parts of the triangle.

APPLICATION *of Geometry and Algebra to Phyſics.*—This we owe to Sir Iſaac Newton, as we owe the application of algebra to geometry to Des Cartes, and it is founded on the ſame principles. The properties of bodies in general have between each other certain proportions, which we may compare with each other, more or leſs diſtinguiſhable; and theſe we can diſcover by geometry or algebra. On this are founded all the phyſico-mathematical ſciences. One ſingle obſervation or experiment often demonſtrates a whole ſcience. As for example: The bare knowledge of this, that the angle of incidence is equal to the angle of reflection, which is known to be true, contains the whole ſcience of catoptrics. This principle of the equality of angles being once admitted, catoptrics becomes a ſcience purely geometrical, becauſe it is reduced to comparing angles with given lines of poſition. The thing is the ſame in many other caſes. By the help of geometry and algebra, we can in general determine the power of one effect, which depends on another better known. This ſcience, therefore, is almoſt always neceſſary to compare and examine the facts experiments diſcover to us. It muſt be owned, however, that every ſubject of phyſics is not equally capable of the application of geometry. Several experiments admit of no calculation at all; ſuch are thoſe of the magnet, electricity, and many others; in theſe caſes we muſt forbear applying to it. Geometricians, however, are apt to run into this fault, by advancing hypotheſes on experiments, and proceeding to calculations according to theſe hypotheſes; but theſe calculations ought no farther to be regarded, than as the hypotheſes on which they are ſupported are conformable to nature; and, therefore, obſervations ought to confirm them, which unfortunately ſometimes does not happen. Beſides, ſuppoſing the hypotheſes true, they are not always ſufficient. If there be in an effect a great number of circumſtances owing to ſeveral cauſes, which act all together, and we content ourſelves with conſidering ſome of theſe cauſes only, which, being more ſimple, can be calculated more eaſily; we may gain a partial effect of theſe cauſes; but it will be very different from the total effect which would reſult from uniting all the cauſes.

APPLICATION *of a geometrical Method in Metaphyſics.*—Geometry has been ſometimes abuſed in phyſics by applying the calculation of the properties of bodies to arbitrary hypotheſes. A geometrical method has alſo been miſapplied in ſciences, which in their own nature ſubmit to no calculation, I mean the method only, not the ſcience. Several metaphyſical writers, who have publiſhed certain truths, have yet, copying after the manner of geometricians, ridiculouſly enough ſwelled their page with the pompous words axiom, theorem, corollary, &c.

The authors of theſe works certainly imagined that theſe words, by ſome ſecret charm, compoſed the eſſence of a demonſtration; and that by writing at the end of a propoſition that it might be demonſtrated, they ſhould make that demonſtrable which was not really ſo. Geometry does not owe its certainty to this method, but to the evidence and ſimplicity of its object: and though a treatiſe on geometry, when diveſted of its ordinary terms, may be very good; yet a treatiſe on metaphyſics may be often very bad, by the affectation of following a geometrical method. We ought even to diſtruſt this claſs of writers; for the generality of their pretended demonſtrations are only founded upon an abuſe of words.

Thoſe who have conſidered theſe things, know how common and eaſy the abuſe of words is, eſpecially in metaphyſical ſubjects. It is in this particular the ſchoolmen have excelled; and it is pity they made no better uſe of their ſagacity.

APPLICATION *of Metaphyſics to Geometry.*—Metaphyſics are ſometimes miſapplied in geometry, as well as geometry in metaphyſics proper to itſelf, which is certain and inconteſtable; becauſe the geometrical propoſitions which reſult from it, afford an evidence which demands our aſſent. But as mathematical certainty ariſes from the ſimplicity of its objects, its metaphyſics too muſt be extremely ſimple and clear; muſt always be capable of being reduced to perfect ideas, without any obſcurity. In ſhort, how can the conſequences of any thing be certain and evident, if the principles are not ſo? Yet ſome authors have thought themſelves able to introduce into geometry a kind of metaphyſics, often obſcure; and, what is ſtill worſe, have affected to demonſtrate, metaphyſically, truths which have been already eſtabliſhed on other principles: this ſurely was the way to render thoſe truths doubtful, if they could poſſibly be ſo. The new geometry has principally occaſioned this falſe method. By conſidering parts infinitely ſmall as real quantities, and admitting ſome of theſe to be greater and ſome leſs, they have acknowledged an infinity of ſmall particles of different claſſes; and looked on them as real ſomethings, inſtead of endeavouring to reduce theſe ſuppoſitions and calculations to ſimple ideas.

Another abuſe of metaphyſics in geometry conſiſts in confining metaphyſics to geometrical demonſtrations. Admitting even the metaphyſical principles we ſet out upon to be certain and evident, there are ſcarce any geometrical theorems that can be accurately demonſtrated by their help alone; they almoſt always require lines and calculations: this manner of demonſtration is very material, becauſe it is in ſhort the only ſure and certain method; ſince with our pens, not metaphyſical reaſonings, we can make combinations and certain calculations.

This latter kind of metaphyſics, which we have been ſpeaking of, is however uſeful to a certain degree, provided we do not confine ourſelves too much: it makes us carefully examine the principles of diſcoveries; it furniſhes us with lights; it points out to us the road; but we are not ſure of being right, if we may be allowed the expreſſion, without the ſtaff of calculation to point out the proper objects which we before ſaw confuſedly.

One would think great geometricians ought always to be excellent metaphyſicians; at leaſt in the objects of their ſcience. This is not however always the caſe: ſome geometricians are like people who poſſeſs a ſenſe of ſeeing, contrary to that of feeling; this proves yet more how neceſſary calculation is in geometrical truths. One may venture to affirm, that the geometrician who is a bad metaphyſician in the objects he applies himſelf to, will in others be intolerable: though geometry, whoſe object is the menſuration of body and matter, may in ſome caſes be applied to thought.

APPLICATION *of one Thing to another* is a term made uſe of to denote the ſervice the firſt is of to underſtand or bring the ſecond to perfection. Thus the application of the cycloid to pendulums ſignifies the uſe made of the cycloid to bring pendulums to perfection.

APPOGIATURA, in muſic, implies a ſmall note inſerted by practical muſicians between two others at ſome diſtance.

APPORTIONMENT, in law, the diviſion of a rent into parts, in the ſame manner as the land out of which it iſſues is divided.

APPOSITION, in grammar, ſignifies the placing two or more ſubſtantives together in the ſame caſe, without any conjunction copulative between them.

APPOSITION, among naturaliſts, is the ſame with juxta-poſition. See the article JUXTA-POSITION.

APPRAISING, the act of valuing or ſetting a price upon goods.

APPREHENSION, in logic, the firſt or moſt ſimple act of the mind, whereby it perceives or is conſcious of ſome idea. See the article PERCEPTION.

APPREHENSION, in law, implies the ſeizing a criminal in order to bring him to juſtice.

APPRENTICE, a young perſon bound by indenture to ſome tradeſman, in order to be inſtructed in his myſtery or trade.

APPROACH, the acceding or advancing of two objects towards each other.

APPROACHES, in fortification, the works thrown up by the beſiegers, in order to get nearer a fortreſs without being expoſed to the fire of the enemy's cannon; ſuch in particular are the trenches carried on in a zigzag form, connected by parallels or lines of communication. See the article ATTACK.

The lines of approach are repreſented on plate V. *fig.* 2. extending from D, D, towards the baſtions A, B.

APPROACHING, in gardening; ſee the article GRAFTING *by Approach*.

APPROPRIATION, the annexing a benefice to the proper and perpetual uſe of a religious houſe, biſhopric, college, &c.

APPROVER, in law, implies a perſon who, having been concerned in committing a felony, accuſes one or more of his accomplices.

APPROXIMATION, in arithmetic and algebra, is the method of approaching ſtill nearer and nearer to the quantity ſought, without a poſſibility of finding it exactly.

The word is Latin, *approximatio*, and compounded of *ad*, to, and *propinquo*, to approach.

For the ſeveral methods of approximation, ſee EXTRACTION, EQUATION, CIRCLE, SERIES, &c.

APPUI, in the manege, implies the ſenſe of the action of the bridle in the horſeman's hand.

APPULSE, in aſtronomy, the approach of a planet towards a conjunction with the ſun, or any of the fixed ſtars.

APPURTENANCES, in common law, ſignify whatever things belong to another thing as principal: as hamlets, fiſheries, &c. to a manor; ſeats in a church to houſes, &c.

APRICOT-TREE, *Armeniaca Malus*, in gardening and botany, a fruit-bearing-tree, with roundiſh acuminated leaves, ſerrated on the edges, and four or five of them placed together. The flowers that come out early in the ſpring, before the leaves, are roſaceous, conſiſting of five whitiſh petals, diſpoſed in a ring, with a calyx divided into five ſegments, from which a piſtil ariſes that turns to a fleſhy ſucculent fruit, very well known. There are ſeven ſorts cultivated in the Engliſh gardens, which are: 1. The maſculine apricot, that is the ſooneſt ripe of all, and has a ſmall roundiſh fruit, of a red colour towards the ſun, which as it ripens fades to a greeniſh yellow on the other ſide. It is only valuable for being ſooneſt ripe; for it has little flavour. 2. The Orange apricot, which is the next that becomes ripe, and is of a deep yellow colour. The fleſh is dry, and is better for tarts than for eating. 3. The Algier apricot ripens next, and is of an oval ſhape, only a little compreſſed on the ſides. It turns to a pale yellow or ſtraw-colour, when the fleſh is dry, with a faintiſh taſte. 4. The Roman is next, and is larger than the Algier, but not compreſſed on the ſides; the colour is deeper, and the fleſh is moiſter. 5. The Turky apricot is the next in order, becauſe it ripens later than the former, and is bigger than any of them, and has a globular ſhape. It is of a deeper colour, has a firmer fleſh, and a better taſte. 6. The Breda apricot was brought originally from Africa, and is a large roundiſh fruit, turning to a deep yellow when ripe, and is of a deep orange colour on the inſide. The fleſh is ſoft, full of juice, and better taſted than any of the whole tribe. 7. The Bruſſels apricot is the lateſt, it not being ripe till near the middle of Auguſt, unleſs expoſed to a ſouth ſun; however, too much heat ſpoils the taſte. It is red on the ſide next the ſun, with many dark ſpots, and of a greeniſh yellow on the other ſide; the fleſh is firm, and of a high flavour, but it often cracks before it is ripe.

Moſt people train theſe trees up to ſtems of ſix or ſeven feet high, or breed them upon ſtocks of that height; but this is a bad practice, becauſe the higher the heads of theſe trees are, the more they are expoſed to the cutting winds in the ſpring, which too frequently deſtroy the bloſſoms; and the fruit is alſo more liable to be blown down in ſummer, eſpecially if there ſhould happen to be much wind at the time they are ripe; which by falling from a great height, will be bruiſed and ſpoiled. Half ſtandards of about two feet and a half, or three feet in the ſtem, will better anſwer the intention; or they may be placed as dwarfs againſt an eſpalier, where, if they are ſkilfully managed, they will produce a large quantity of good fruit; and the trees in eſpalier may be more conveniently covered in ſpring, when the ſeaſon proves bad; whereby there will be a certainty of fruit every year.

Theſe fruits are all propagated by breeding them on plum-ſtocks, and will readily take upon almoſt any ſort of plum, except the Bruſſels, provided the ſtock be free and thriving.

Moſt of theſe trees are planted againſt walls, and ſhould have an eaſt or weſt aſpect; for if they are planted full ſouth, the great heat renders them mealy before they are well eatable. The borders under theſe walls ſhould be ſix feet wide at leaſt, and the earth about two feet, or two feet and a half deep.

If your ground be a wet cold loam or clay, you ſhould raiſe your borders as much above the level of the ſurface as it will admit, laying ſome ſtones or rubbiſh in the bottom, to preſerve the roots from running downwards; but if you plant upon a chalk or gravel, you muſt remove it to a conſiderable width to make room for a good ſoil to be put in its place; tho' you need not go above two feet and a half deep at moſt.

The beſt ſoil for theſe and all other ſort of fruit-trees is freſh untried earth from a paſture ground, taken about ten inches deep with the turf, and laid to rot and mellow at leaſt twelve months before it is uſed; and this muſt be kept often turned to ſweeten and imbibe the nitrous particles of the air.

When the former ſoil of the border is taken away, this freſh earth ſhould ſupply its place; and if the borders are filled with it two months before the trees are planted, the ground will be better ſettled, and not ſo liable to ſink after the trees are planted. In filling the borders the ground ſhould be raiſed four or five inches above the level they are deſigned to allow for the ſettling.

Your borders being thus prepared, make choice of ſuch trees as are but one year's growth from budding; and if your ſoil be dry, or of a middling temper, you ſhould prefer October as the beſt ſeaſon for planting; but do not cut off any of the head at that time, unleſs there be any ſtrong fore-right ſhoots which will not come to the wall, and muſt therefore be taken away.

Your trees being thus prepared, mark out the diſtances they are to ſtand, which, in a good ſtrong ſoil, or againſt a low wall, ſhould be twenty feet or more; but if the wall be moderately high, eighteen feet is a reaſonable diſtance. Make a hole where each tree is to ſtand, and place the ſtem about four inches from the wall, inclining thereto: and after having fixed the tree in the ground, nail the branches to the wall, to prevent their ſhaking, and cover the ſurface of the ground round the roots with rotten dung to keep out the froſt. In this ſtate let it remain till February, when, if the weather be good, you muſt unnail the branches of your trees, taking care not to diſturb the roots; and being provided with a ſharp knife, put your foot cloſe to the ſtem of the tree, and having placed your left-hand to the bottom of the tree, to prevent its being diſturbed, with your right-hand cut off the head of the tree, to about four or five eyes above the bud, ſo that the ſloping ſide may be towards the wall.

In the ſpring, if the weather proves dry, you muſt now and then give your trees a gentle refreſhing with water; in the doing of which, if you obſerve to water them with a roſe to the watering-pot, all over their heads, it will greatly help them; and alſo lay ſome turf or other mulch about the roots, to prevent their drying during the ſummer ſeaſon. As new branches are produced, obſerve to nail them to the wall in a horizontal poſition; and diſplace ſuch ſhoots as grow in a fore-right direction. This muſt be repeated as often as neceſſary, to prevent their hanging from the wall; but by no means ſtop any of their ſhoots in ſummer.

At Michaelmas, when the trees have done growing, you muſt unnail the branches, and ſhorten them in proportion to their ſtrength; a vigorous branch may be left eight or nine inches long, but a weak one not above five or ſix: by this means no part of the wall will be left uncovered with bearing wood, which muſt be the caſe if the branches are left to a great length at firſt; for it ſeldom happens that more buds than two or three ſhoot for branches; and theſe are, for the moſt part, ſuch as are at the extreme part of the laſt year's wood: ſo that all the lower part of the ſhoots become naked, nor will they ever after produce ſhoots; and this is the reaſon we ſee ſo many trees which have their bearing-wood ſituated only in the extreme part of the tree.

When you have ſhortened the ſhoots, be ſure to nail them as horizontally as poſſible; for upon this precaution the future good of the tree depends.

The ſecond ſummer obſerve, as in the firſt, to diſplace all fore-right ſhoots as they are produced, nailing in the other cloſe to the wall horizontally, ſo that the middle of the tree may be kept open; and never ſhorten any of the ſhoots in ſummer, unleſs to furniſh branches to fill vacant places on the wall; and never do this later than April. At Michaelmas ſhorten theſe ſhoots, as was directed for the firſt year; the ſtrong ones may be left nine inches, and the weak ſix or ſeven at moſt.

The following year's management will be nearly the ſame with this; but only obſerve, that apricots produce their bloſſom-buds, not only upon the laſt year's wood, but alſo upon the curſons, or ſpurs, which are produced from two years wood: great care ſhould therefore be taken in the ſummer-management, not to hurt or diſplace theſe. Obſerve alſo to ſhorten your branches at the winter-pruning, ſo as to furniſh freſh wood in every part of the tree; and be ſure to cut out entirely all the luxuriant branches, or diſplace them as ſoon as they are produced; becauſe if they were left to grow, they would exhauſt the nouriſhment from the bearing branches, which cannot be too ſtrong, provided they are kindly; for the more vigorous your tree is, the more likely it will be to reſiſt the injuries of the weather: and trees are often brought to ſo weak a condition, as to produce only faint bloſſoms, and then moſt or all of the bearing branches will die. This misfortune, which is entirely owing to miſmanagement, is generally conſidered as the effect of a blight; and perhaps moſt of the blights we complain of proceed from the ſame cauſe.

Theſe few rules well executed, together with a little obſervation and care, will be ſufficient; for without diligent obſervation, there can be no ſuch thing as a ſkilful manager, be his inſtructions what they will.

The Bruſſels and Breda apricots, being for the moſt part planted for ſtandards, will require very little pruning or management; only obſerve to take out all dead wood, or ſuch branches as croſs each other: this muſt be done early in autumn, or in the ſpring after the cold weather is paſt, that the part where the inciſion is made may not canker. *Miller's Gardener's Dictionary.*

APRIL, in chronology, the fourth month of the year, containing thirty days.

The word is formed from the Latin *Aprilis*, which is derived from *aperio*, to open, becauſe the buds begin to open during this month.

A-PRIORI *demonſtration.* See DEMONSTRATION.

APRON, in gunnery, the piece of lead which covers the touch-hole of a piece of ordnance.

APSIS, in aſtronomy, a term uſed indifferently of either of the two points of a planet's orbit, where it is at greateſt or leaſt diſtance from the ſun or earth; and hence the line connecting thoſe points is called the line of the apſides.

The word is Greek, and derived from απτω, to connect. The apſis at the greateſt diſtance from the ſun is called the aphelion, and at the greateſt diſtance from the earth the apogee; while that at the leaſt diſtance from the ſun is termed the perihelion, and at the leaſt diſtance from the earth, the perigee. See APHELION, APOGEE, &c.

APSIS, among eccleſiaſtical writers, implies the inner part of the ancient churches, anſwering to what is at preſent called the choir.

APSIS is alſo uſed by ſome writers for the biſhop's ſeat or throne.

APTHANES. See ABTHANES.

APTOTE, in grammar, ſignifies an indeclinable noun, or one which has no variation of caſes.

The word is Greek, and compounded of α, priv. and πτωσις, a caſe.

APUS, or the bird of Paradiſe, in aſtronomy, a conſtellation in the ſouthern hemiſphere, not viſible in our latitude. It is near the ſouthern pole, between the triangulum auſtrale, and the chameleon; and conſiſts of eleven ſtars.

In the year 1677, Dr. Halley obſerved the longitude and latitude of the ſtars in Apus, which Hevelius, in his Prodromus, reduced, with ſome alteration, to the year 1700.

APYREXY, among phyſicians, implies the intermiſſion of a fever.

The word is Greek, απυρεξια, compounded of α, priv. and πυρ, fire, or heat.

AQUA, water. See the article WATER.

AQUA-FORTIS, a corroſive liquor diſtilled from nitre and vitriol, in the following manner.

Put vitriol into an earthen or iron pot; if you make a fire under it, the vitriol begins to melt and ſmoak; by increaſing the fire gradually, it thickens and aſſumes an aſh-colour. Let it be ſtirred with a twig before it becomes ſolid, till it be perfectly dry; but let it be taken as yet boiling out of the pot; for if it grows cold therein, it will ſtick ſo faſt that you will hardly be able to get it out. Pound to a ſubtile powder three pounds weight of this calcined vitriol, and mix them well with four pounds of nitre well dried, and pulverized very fine. Put theſe together in a cucurbit, or retort, or an iron-pot, and then put it in a furnace.

At firſt, let the fire be made not much greater than is neceſſary to boil water. When the recipient grows warm, continue the ſame degree of fire, till all the phlegm is expelled, which you will know from the diminution of the heat of the recipient: increaſe the fire gradually, till you ſee a few yellow vapours ariſe. Keep up the ſame fire for an hour or two, and make it ſo ſtrong as to warm the veſſels moderately. Continue this for ſome hours, and letting the veſſels cool, pour the liquor, now emitting reddiſh fumes, out of the recipient into a glaſs veſſel, having a glaſs ſtopple: this liquor thus prepared is your aqua-fortis.

For ſecurity's ſake, you muſt leave, in the cloſure of the recipient and veſſel that contains the matter to be diſtilled, a hole, which may be ſtopped and opened with a wooden peg; for if you happen to exceed the juſt degree of fire, eſpecially in the beginning of the operation, the firſt and more ſubtile ſpirits, which are very elaſtic, come forth; the opening therefore of the hole may give them a paſſage, leſt the veſſels ſhould burſt, which would be very dangerous.

There are many other ingredients uſed in the making of aqua-fortis, ſuch as burnt alum, ſand, and the like; the reaſon whereof is to hinder the ſpecies, which may happen not to be ſufficiently calcined, from fuming, and breaking the veſſel with great violence. But when theſe ſpecies are duly calcined and dried, theſe additions are quite needleſs; and, indeed, by overſwelling the maſs to be diſtilled, require veſſels of a ſize proportionable.

There are many other needleſs and noxious ingredients, uſed by ſome in making aqua-fortis. Theſe are bloodſtones, unſlaked lime, plume alum, &c. all which ſhould be avoided, they making a much worſe, as well as a more expenſive aqua-fortis. A menſtruum thus made, therefore, ſhould never be uſed in docimaſtical operations before it has been accurately tried; for aqua-fortis being tainted with theſe heterogeneous matters, the major part of it conſumes away, and becomes frequently ſo fixed, that the ſtrongeſt fire is hardly able to take off any of it. Nothing ſhould be uſed beſides calcined vitriol, intimately mixed with nitre, there being no need of any thing elſe.

However, bole, clay, and brick-duſt, expel aqua-fortis out of nitre, which then is called the ſpiritus nitri; but you muſt add four times as much of theſe, in proportion to the nitre: conſequently this method, requiring larger veſſels and more fire, cannot be ſo profitable as without theſe ingredients.

As the extracted ſpirits of nitre are with difficulty condenſated into drops, eſpecially in ſultry weather, it will be proper, by reaſon of the calcined ingredients, to pour into the recipient one quarter part of pure water, or rather of the phlegm, extracted out of the aqua-fortis; by which means the ſpirits will be much eaſier received.

AQUA-MARINA, in natural hiſtory, the name of a precious ſtone of a colour compounded of green and blue, nearly reſembling that of ſea-water, from whence the name.

It ſeems very probable that the ancients knew it under the name of the beryl-ſtone; for Pliny obſerved that the moſt beautiful beryls were thoſe that imitated the colour of ſea-water; he likewiſe diſtinguiſhes ſeveral ſorts of beryls, which bear no reſemblance with our aqua-marina; as the chryſoberyls, which were of a golden colour. Whatever the ancients called the aqua-marina, we are now to endeavour to find out a ſure means to diſtinguiſh this precious ſtone from all others. The colour being a mixture of green and blue, we cannot confound it either with green or blue ſtones, as the emeralds and the ſaphires: for if we ſuppoſe the emerald of a pure green, without any tincture of blue, and the ſaphire blue as indigo, and free from any tincture of green, we may eaſily diſcover that all ſtones compounded of green and blue, can neither be emeralds nor ſaphires. This mixture of an emerald-colour with that of a ſaphire, that is, of green and blue, deſcribes ſo well the aqua-marina, that it ſeems impoſſible to be miſtaken: not but that there are ſome of theſe ſtones, where the green is more predominant than the blue; as well as others, where the blue is more powerful than the green. Theſe ſtones are very different from each other, with reſpect to their hardneſs. The oriental are reckoned the hardeſt, and bear the fineſt poliſh, and conſequently are more beautiful, more ſcarce, and dearer than the occidental.

The moſt beautiful aqua-marinas comes from the Eaſt-Indies; and it is ſaid that ſome of them are found on the borders of the Euphrates and at the foot of Mount Taurus. The occidental ones come from Bohemia, Germany, Sicily, the Iſle of Elba, &c. And it has been affirmed that ſome of them have been found on the ſea-ſhore.

AQUA-REGIA, a corroſive menſtruum that has the power of diſſolving gold.—It is made in the following manner.

Take one pound of common ſalt; melt it in a clean crucible or iron ladle; pour it out into an iron mortar, and when cold break it into ſmall pieces. Put theſe into a retort, and pour upon them twice their weight of good aqua-fortis. Place the retort in a ſand furnace; lute on a receiver, and apply a gradual fire, till no more liquor drops from the noſe of the retort.—An aqua-regia may alſo be made, by mixing one part of ſpirit of ſalt with three of aqua-fortis; or by diſſolving the ſame quantity of ſal-armoniac in it: but this ſhould be done ſlowly, and by degrees, otherwiſe great quantities of offenſive fumes will ariſe.

This menſtruum diſſolves iron, copper, tin, gold, mercury, regulus of antimony, biſmuth, and zinc; but not ſilver, unleſs it be deficient in ſtrength.

AQUÆDUCT, in architecture and hydraulics, a canal ſupported by ſtone, timber, &c. for conveying water from one place to another.

The word is Latin, *aquæductus*, q. d. *ductus aquæ*, a conduit of water.

The Romans, and ſeveral oriental nations, were very magnificent in their aquæducts, ſome of which extended an hundred miles. Frontinus, a man of conſular dignity, and who had the direction of the aquæducts under the emperor Nerva, mentions nine of theſe ſtructures that emptied themſelves through 13,594 pipes of an inch diameter. And Vigenere has obſerved that Rome received, every twenty-four hours, no leſs than 500,000 hogſheads of water.

AQUÆDUCT, in anatomy, a term applied by anatomiſts to certain canals, on account of their form or uſe: ſuch are the aquæduct of Fallopium, a canal ſituated between the apophyſes, ſtyloides, and maſtoides; the aquæduct of Nuck, in the ſclerotic coat of the eye; and the aquæduct of Sylvius, in the brain, the poſterior ſurface of which is called its anus.

AQUARIANS, in eccleſiaſtical hiſtory, a ſect of Chriſtians in the primitive church, who conſecrated water in the Euchariſt, inſtead of wine, under pretence of abſtinence and temperance; or becauſe they thought it univerſally unlawful to eat fleſh, or drink wine.

Epiphanius calls them Eucratites, from their abſtinence; St. Auguſtine, Aquarians, from their uſe of water; and Theodoret, who ſays they ſprang from Tatian, Hydroparaſtatæ, becauſe they offered water inſtead of wine.

Beſides theſe, there was another ſort of Aquarians, who did not reject the uſe of wine as unlawful; for they adminiſtered the Euchariſt in wine at evening ſervice: but, in their morning aſſemblies, they uſed water, for fear the ſmell of wine ſhould diſcover them to the heathens.

St. Cyprian, who gives a long account of theſe in one of his epiſtles, tells us, it was the cuſtom of the church to uſe water mixed with wine, becauſe the water repreſents the people, as the wine does the blood of Chriſt; and when both are mixed together in the cup, then Chriſt and his people are united. The council of Carthage confirmed this practice: and Gennadius aſſigns two reaſons for it; firſt, becauſe it is according to the example of Chriſt; and ſecondly, becauſe, when our Saviour's ſide was pierced with the ſpear, there came out water and blood. The author of the Commentaries on St. Mark under the name of St. Jerom, gives another reaſon for mixing water with wine, namely, that by the one we may be purged from ſin; and by the other, redeemed from puniſhment. But there is no expreſs command for this; nor is it at all eſſential to the ſacrament.

AQUARIUS, in aſtronomy, a conſtellation which makes the eleventh ſign in the zodiac, marked thus, ♒. It conſiſts of forty-five ſtars in Ptolemy's catalogue, of forty in Tycho's, and in the Britannic catalogue of ninety-nine.

AQUATIC, in natural hiſtory, is an appellation given to ſuch things as live or grow in the water.

AQUEDUCT, the ſame with aquæduct. See AQUÆDUCT.

AQUEOUS, ſomething abounding with water, or that partakes of its nature.

The word is formed from the Latin, *aquoſus*, which is derived from *aqua*, water.

AQUEOUS *Humour*, in anatomy, called alſo the albugineous humour, is the utmoſt of the three humours of the eye, and fills up both its cameræ. In this the uvea fluctuates as it were, and moves at liberty; this humour alſo, when loſt, will be repaired by nature.

AQUIFOLIUM, or AGRIFOLIUM, the holly tree, in botany, is an ever-green ſhrub very well known, and was formerly planted in gardens, as an ornament.

The wood is hard and ſolid, and is ſo heavy it will ſink in water. The flowers are ſmall, monopetalous, and divided into four ſegments, with as many ſtamina, and a flower-cup divided into four parts, from which a piſtil ariſes, fixed into the hinder part of the flower, like a nail; it changes to a ſoft fruit, or berry, which is round, imbricated, and red, and is full of whitiſh ſtones.

The manner of raiſing this ſhrub is by ſowing the berries as ſoon as they are ripe, where they will continue a year and a half before they ſpring. The beſt time of tranſplanting this tree is in the beginning of April, in moiſt weather, and then there will be little danger of their growing. It was formerly uſed as a medicine, but is now entirely laid aſide. Some uſe the bark for making bird-lime.

AQUILA, the eagle, in natural hiſtory. See the article EAGLE.

AQUILA, in aſtronomy, a conſtellation of the northern hemiſphere, conſiſting of fifteen ſtars in Ptolemy's catalogue, of ſeventeen in Tycho's, and of ſeventy in the Britannic catalogue.

AQUILA *Marina*, the ſea-eagle, the name of a fiſh of the paſtinacha kind, with a head reſembling, in ſome meaſure, that of a toad.

AQUILEGIA, *Columbine*, in botany, a plant with a branched and fibrous root, of a ſweetiſh taſte. It has leaves like meadow rue, cut on the edges, and bluiſh underneath, but above of a dark green. The flowers are pendulous, and conſiſt of many petals different from each other; from the middle of the flower ariſes the piſtil, beſet with ſtamina, which turns to a membraneous fruit, conſiſting of many huſks, or pods, each of which is full of black ſhining ſeeds. The colours of the flowers are various, as blue, red, white, fleſh-coloured, and green, upon which account it is cultivated in gardens, and they flower in May and June. For raiſing them, the ſeeds ſhould be ſown in a nurſery-bed in September, and in March following the young plants will appear above ground, which ſhould be tranſplanted in the middle of May into good freſh earth, and ſet at nine inches diſtant every way. At Michaelmas they may be removed into the borders of a flower-garden, and the May following they will produce flowers. It has been looked upon as an aperient and ſudorific; but it is now out of uſe.

AQUILICIA, or AQUILICIANA, in antiquity, ſacrifices performed by the ancient Romans, in times of exceſſive drought, to obtain rain from the gods.

AQUOSE, the ſame with aqueous. See AQUEOUS.

ARA, the altar, in aſtronomy, a conſtellation of the ſouthern hemiſphere, conſiſting of eight ſtars.

ARABESQUE, or ARABESK, ſomething done after the manner of the Arabians.

ARABIAN, ſomething that relates to Arabia, or the Arabs.

ARABIAN, or ARABIC *Tongue*, is a branch or dialect of the Hebrew.

Father Angelo de St. Joſeph ſpeaks much of the beauty and copiouſneſs of the Arabic. He aſſures us it has no leſs than a thouſand names for a ſword; five hundred for a lion; two hundred for a ſerpent; and eighty for honey.

ARABIAN *Figures* or *Characters*, the numeral figures commonly uſed in arithmetical computations.

The origin of theſe characters has been a ſubject of diſpute in the republic of letters. The learned are generally of opinion that the Arabic figures were firſt taught us by the Saracens, who borrowed them from the Indians. Scaliger was ſo ſatisfied of their novelty, that he immediately pronounced a ſilver medallion he was conſulted about, modern, upon his ſeeing of the numeral figures 234, 235, on it. The common opinion is, that Planudes, who lived towards the cloſe of the thirteenth century, was the firſt Chriſtian who made uſe of them. Father Mabillon even aſſures us, in his work De Re Diplomatica, that he has not found them any where earlier than the fourteenth.

Yet Dr. Wallis inſiſts on their being of a much older ſtanding; and concludes they muſt have been uſed in England, at leaſt as long ago as the time of Hermannus Contractus, who lived about the year 1050; if not in ordinary affairs, yet at leaſt in mathematical ones, and particularly aſtronomical tables. *Vid. Wall. Algeb.*

The ſame author gives us an inſtance of their antiquity in England, from a mantle tree of a chimney in the parſonage houſe of Helendon in Northamptonſhire, wherein is the following inſcription in baſſo relievo, M°. 133, being the date of the year 1133. *Philoſ. Tranſact.* N°. 255.

Mr. Luffkin furniſhes a yet earlier inſtance of their uſe, in the window of a houſe, part of which is a Roman wall, near the market-place in Colcheſter; where between two carved lions ſtands an eſcutcheon, containing the figures 1090. *Philoſ. Tranſact.* N°. 255.

Mr. Huet is even of opinion, that theſe characters were not borrowed from the Arabs, but from the Greeks; and that they were originally no other than the Greek letters, which we all know that people made uſe of to expreſs their numbers by.

ARABIAN *Philoſophy*, the ſtate of philoſophy among the ancient Arabians.

Authors of great antiquity inform us, that the ancient Arabians applied themſelves very much to philoſophy, and diſtinguiſhed themſelves by a peculiar and ſuperior ſagacity: but all they ſay on this head ſeems very uncertain. Indeed, after Iſſamim, learning and the ſtudy of philoſophy were greatly eſteemed among this people; but this has no place in hiſtory till we come to the philoſophy of the middle age; and, conſequently, proves nothing with regard to the philoſophy of the ancient inhabitants of Arabia Felix.

Some men of letters have aſſerted, that the ancient Arabs applied themſelves to philoſophical ſpeculations; and to maintain their opinion, raiſe imaginary ſyſtems which they attribute to them, and draw in the religion of the Sabeans to their aid, which they pretend to have been the offspring of philoſophy. But all they advance in favour of this opinion is founded on aſſertions and conjectures; and what are thoſe where proof and teſtimony are wanting? They are even forced to acknowledge that the Greeks were of another opinion, looking on them as a moſt barbarous and ignorant people, without the leaſt tincture of learning. If credit may be given to Abulfaragius, the Arabian writers themſelves confeſs, that before Iſſamim they were ſunk into the deepeſt ignorance.

Theſe reaſons, however, do not ſeem ſtrong enough to thoſe on the other ſide of the queſtion, to induce them to retract their opinion of the philoſophy they attribute to the ancient Arabs. The contempt the Greeks expreſs for this nation, ſay they, proves only the pride of the Greeks, not the barbariſm of the Arabians. But what authority can they produce, or what writers can they quote, in favour of their opinion concerning the philoſophy of the ancient Arabians? They agree with Abulfaragius, that there are none; this opinion therefore ſtands on a very weak foundation.

Joſeph Peter Ludewig has ſignalized himſelf moſt in this diſpute, and ſeems to have had the honour of the ancient Arabians very much at heart. He ſets out in this manner: "Pythagoras, ſays he, as Porphyry relates, in his travels to improve his learning, did the Arabians the honour of a viſit; ſtaid ſome time among them, and learned, of their philoſophers, divination by the chirping and flight of birds; an art in which they excelled.

Moſes himſelf, inſtructed in all the learning of the Egyptians, choſe Arabia for a retreat in his exile, preferable to other countries. Can one imagine the great legiſlator of the Hebrews would have choſe this retreat if the people had been barbarous, ſtupid, and ignorant? Beſides, their origin leaves no room to doubt of the improvement of their mind: they boaſt of their lineage from Abraham, whom no one can deny to have been a great philoſopher. By what ſtrange accident is that ſpark of philoſophic ſpirit extinguiſhed, which they inherited from their common father Abraham? But what yet appears a ſtronger argument is this, that the ſacred writings, to give a more exalted idea of Solomon's wiſdom, place it in oppoſition to the wiſdom of the wiſe men of the Eaſt, which is certainly Arabia. From Arabia alſo came the queen of Sheba to admire the wiſdom of the philoſopher, inveſted with a diadem; this has been the conſtant opinion of all men of erudition. It is eaſy to prove that the Magi, who came out of the Eaſt to worſhip our Saviour, were Arabians. In ſhort, Abulfaragius is obliged to agree, that before the time of Iſſamim, to whom the revival of learning in that country is owing, they were perfect maſters of their own language, good poets, excellent orators, and able aſtronomers. Is not this enough to give them a right to the title of philoſophers?"

No, it may be replied, the Arabians might have poliſhed their language, have ſucceeded in compoſition, have been ſkilful in the ſolution of riddles, and interpretation of dreams; nay, though it be admitted they had ſome knowledge of the courſes of the ſtars, it will not follow they were philoſophers; for all thoſe arts, if they merit the name, tend more to increaſe and encourage ſuperſtition, than to diſcover truth, or diveſt the ſoul of the paſſions which enſlave it. As to what concerns Pythagoras, nothing is more uncertain, than whether he travelled into the Eaſt or no: but, admitting he did, what are we to conclude, but that he learned from the Arabians all thoſe ſuperſtitious and extravagant notions he was ſo extremely fond of. It is needleſs to quote Moſes here; if this great man went into that country, and ſettled there, by marrying one of Jethro's daughters, it certainly was not with a deſign of ſtudying and encouraging them in their fooliſh curioſity in philoſophical ſyſtems. Providence permitted this retreat of Moſes among the Arabians, to carry among them the knowledge of the true God, and his religion. The philoſophy of Abraham, from whom they boaſt their deſcent, by no means proves their having cultivated this ſcience. Abraham might have been their primogenitor, and a great philoſopher; but their philoſophy is no neceſſary conſequence of this. If they loſt the thread of thoſe moſt valuable truths they had learned from Abraham; if their religion degenerated into groſs idolatry; why might not their philoſophy, admitting Abraham to have taught it them, have been loſt alſo in courſe of time? Beſides, it is not certain that theſe people deſcended from Abraham. This is a traditionary tale, that ſeems to have taken birth with Mahometaniſm. The Arabians, like the Mahometans, to give the ſanction of authority to their errors, have pretended to deduce their origin from the father of the faithful. Another thing that overturns Ludewig's hypotheſis, is, that Abraham's philoſophy is a mere device of the Jews, who would fain perſuade us that the origin of all arts and ſciences is to be found among them. What they ſay in ſupport of the queen of Sheba's coming to viſit Solomon on the fame of his wiſdom, or of the wiſe men who came out of the Eaſt to Jeruſalem, will prove nothing more than has been advanced before. Let it be granted that this queen was born in Arabia; is it proved ſhe was of the ſect of the Sabians? No one will pretend to deny her to have been the moſt expert and ſagacious woman of her time; and that ſhe frequently puzzled all the kings of the Eaſt with her wiſe queſtions; becauſe the ſacred writings have given this account of her. But what has this to do with the philoſophy of the Arabians? We acknowledge very freely, that the Magi who came out of the Eaſt were Arabians; that they were not without ſome knowledge of the courſes of the ſtars: we do not abſolutely exclude the Arabians from this ſcience, but admit they ſpoke their native language well; ſucceeded in ſome works of invention, as oratory, poetry; but we are not to infer from hence that they were philoſophers, and had applied themſelves ſtrongly to the cultivation of this part of literature.

A ſecond argument in favour of the philoſophy of the ancient Arabians, and which is urged as a very forcible argument too, is the hiſtory of Sabianiſm, which neceſſarily implies philoſophical knowledge, ſuppoſing all to be true which is ſaid about it. We cannot conclude any thing from thence in favour of this opinion: for Sabianiſm is in itſelf a mixture of ſhameful idolatry and ridiculous ſuperſtition; much more likely to ſubvert and extinguiſh reaſon, than propagate true philoſophy; beſides, it is not agreed in what age this ſect firſt appeared. Men of the greateſt eminence for learning, who have laboured to give light to this paſſage in hiſtory, as Hottinger, Hyde, Pocock, and eſpecially the learned Spencer, confeſs that there is no mention made of this ſect, either by the Greeks or Romans.

We muſt take care not to confound theſe Sabians of Arabia with thoſe mentioned in the annals of the ancient eaſtern church, which were half Jews, half Chriſtians; and boaſted of being the diſciples of St. John the Baptiſt; great numbers of whom, even to this day, inhabit the city of Baſſora, near the banks of the Tigris, and the neighbourhood of the Perſian ſea. The famous Moſes Maimonides has extracted a large account of this ſect from the Arabic writers, and by examining their extravagant and ſuperſtitious ceremonies with attention, has very ingeniouſly juſtified the laws of Moſes in general; which at firſt might give offence to delicacy, if the wiſdom of theſe laws was not ſhewn by their oppoſition to the laws of the Sabians. A ſtronger barrier could not be put between the Jews and Arabians, who were their neighbours.

The Arabian philoſophy was entirely Sabian, and included the ſyſtem and ceremonies of that ſect of idolators. This was what Mahomet laboured ſo ſtrenuouſly to aboliſh; and he is even ſaid by ſome to have carried his oppoſition ſo far as to prohibit the very ſtudy of philoſophy. But his followers by degrees got over that reſtraint; the love of learning increaſed, and the philoſophy of Ariſtotle was eſtabliſhed among them, during the memorable caliphate of Al-Mamon. Avicenna flouriſhed in the eleventh century, and Averrhoes an hundred years after him; ſo that the honour of tranſlating the Greek philoſophy into Arabic, cannot belong to them, notwithſtanding what has been ſaid on that ſubject; though they were doubtleſs the chief propagators of it through the countries of Europe.

Their method of philoſophizing was faulty; they followed Ariſtotle implicitly, and run into all the ſtrange ſuperſtitions of aſtrology. They founded ſchools and academies, became fond of ſubtilties and diſputation, and ſoon divided into different ſects.

As they choſe Ariſtotle for their maſter, ſo they chiefly applied themſelves to that part of philoſophy called logic; and thus became proficients in the knowledge of words, rather than of things: whence they have been called the talking philoſophers, and maſters of the wiſdom of words. Their philoſophy was obſcured by quaint arbitrary terms and notions, and on theſe, inſtead of evident principles, their demonſtrations were founded.

ARABIAN *Poetry*, in the moſt ancient times, was no other than rhiming; for it was deſtitute both of meaſure and cadence. But about the cloſe of the eighth century, and during the caliphate of Al-Raſchid, it became an art, and was regulated by laws of proſody. It however ſtill makes no diſtinction between long and ſhort ſyllables, the whole depending on rhime, a certain number of letters, and the obſervation of certain cenſuræ, formed by carefully diſtinguiſhing the moveable from the quieſcent conſonants. A ſyllable to which a quieſcent letter is added at the end, becomes long by poſition; and, on the contrary, that ſyllable ſhort where it is wanting.

Renaudot tells us, that the Arabian compoſitions in verſe are ſtill wild and irregular, being neither epic, dramatic, nor lyric: in ſhort, not reducible to any particular kind. Their hymns to the Deity, and their tales, are in the ſame ſtyle. Their compariſons, in which they abound, are taken, with very little choice, from tents, camels, hunting, and the ancient manners of the Arabs.

ARABIAN *Phyſic*, and *Phyſicians*, ſucceeded the Grecian, and handed down the art to us, with conſiderable improvements, chiefly in the pharmaceutical and chemical parts.

ARABICI, in eccleſiaſtical hiſtory, the name of a ſect of heretics that appeared in Arabia during the reign of the emperor Severus, about the year 207. Their hereſy conſiſted in holding that the ſoul both dies and riſes again with the body. Origen confuted them ſo fully, that they ingenuouſly acknowledged their error.

Gum ARABIC. See GUM *Arabic.*

ARABISM, an idiom or manner of ſpeaking peculiar to the Arabs, or Arabic language.

ARABLE *Land*, in huſbandry, that which is fit for tillage, or has actually been plowed.

The word is derived from the Latin, *aratrum*, a plow.

ARAC, or ARRAC, a ſpirituous liquor imported from the Eaſt-Indies.

It is extracted from a vegetable juice called toddy, which flows by inciſion from the cocoa-nut tree. This juice, after being fermented, is diſtilled in the common manner, and the produce is the arac.

ARACHNOIDES, in anatomy, is an appellation given to ſeveral different membranes, as the tunic of the cryſtalline humour of the eye, the external lamina of the pia mater, and one of the membranes of the ſpinal marrow.

The word is Greek, and compounded of αραχνη, a ſpider, or ſpider's web, and ειδος, reſemblance; the fineneſs of theſe membranes being ſuppoſed to reſemble that of the ſpider's web.

ARÆOMETER, or WATER-POISE, an inſtrument for meaſuring the denſity or gravity of fluids.

The word is formed from the Greek, αραιως, thin, and μετρεω, to meaſure.

This inſtrument is generally made of a thin glaſs ball with a taper neck, hermetically ſealed at the top, having firſt as much mercury poured into the ball, as will keep it ſwimming in an erect poſition. The neck is divided into equal parts, and properly numbered; ſo that the lightneſs of the fluid is known by the depth the aræometer ſinks in it; it being evident that the heavier any fluid is, the leſs will be the diſtance the inſtrument will ſink in it; and vice verſa.

ARÆOPAGUS. See AREOPAGUS.

ARÆOSTYLE, in architecture, a term uſed by Vitruvius to ſignify the greateſt interval that can be made between columns, and which conſiſts of eight modules, or four diameters. See MODULE.

ARÆOTICS, in medicine, remedies which rarify the humours, and render them proper for being carried off by perſpiration through the pores of the ſkin.

The word is formed from the Greek, αραιωτικος, which is derived from αραιοω, to rarify.

ARAIGNEE, in the military art, ſignifies the branch, return, or gallery of a mine. See the article MINE.

ARANEA TUNICA, or ARANEOSA, in anatomy; ſee the article ARACHNOIDES.

ARANEA CONCHA, the ſpider-ſhell, in natural hiſtory, a name given to ſeveral ſpecies of the murex. See MUREX.

ARBALET, in antiquity, a kind of weapon, generally called at preſent a croſs-bow. See the article CROSS-BOW.

The ancients had alſo large machines of the ſame kind for throwing ſeveral arrows at a time. Theſe were generally called baliſtæ. See BALISTA.

ARBITER, in the civil law, implies a judge nominated by the magiſtrate, or choſen voluntarily by the two contending parties, in order to decide their differences according to law.

The civilians make a difference between arbiter and arbitrator, though both found their power on the compromiſe of the parties; the former being obliged to judge according to the cuſtoms of the law, whereas the latter is at liberty to uſe his own diſcretion, and accommodate the difference in the manner that appears to him moſt juſt and equitable.

ARBITRARY, whatever is left to the choice or determination of men, or not fixed by any poſitive law or injunction. Thus arbitrary fines are mulcts impoſed at the pleaſure of the court or judge.

ARBITRARY *Power*. See DESPOTISM.

ARBITRATION, ARBITRAGE, or ARBITRAMENT, a power given by two or more contending parties to ſome perſon or perſons to determine the diſpute between them.

ARBITRATOR, a private extraordinary judge, choſen by the mutual conſent of both parties, to determine controverſies between them.

ARBOR, the Latin appellation for any tree in general.

ARBOR *Dianæ*. See DIANÆ *Arbor*.

ARBOR, in mechanics, implies the principal part of a machine which ſerves to ſuſtain the reſt; alſo the axis or ſpindle on which a machine turns.

ARBORESCENT, an epithet applied to ſuch objects as reſemble trees.

ARBORIST, a perſon ſkilled in that part of botany which treats of trees.

ARBOUR, in gardening, a kind of ſhady bower, formerly in great eſteem, but of late rejected, on account of its being damp and unwholeſome.

Arbours are generally made of lattice-work, either in wood or iron, and covered with elms, limes, hornbeams; or with creepers, as honeyſuckles, jeſſamines, or paſſion-flowers; either of which will anſwer the purpoſe exceeding well, if properly managed.

ARBUTUS, the ſtrawberry-tree, in botany, a genus of ever-green trees, whoſe leaves are oblong, and ſerrated on the edges: the flower conſiſts of one leaf, and are ſhaped like a pitcher; the fruit is of a fleſhy ſubſtance, and, in its outward appearance, very like a ſtrawberry; but is divided into five cells, in which are contained many ſmall ſeeds.

There are three ſpecies of this tree; 1. The common ſtrawberry-tree. 2. The ſtrawberry-tree with longer flowers, and egg-ſhaped fruit; and 3. The ſtrawberry-tree with double flowers.

This tree has its name from the reſemblance the fruit bears to that of a ſtrawberry, but is of an auſtere ſour taſte; though I have been informed that, in Ireland, where this tree abounds, the fruit is ſold and eaten. In England they are chiefly brought to the markets with ſmall branches of the tree, having ſmall bunches of flowers upon them, and made up into noſegays, with other flowers, and ſome ſprigs of the amomum plinii, or winter cherry; which at that ſeaſon is very acceptable, when there are few flowers to be had.

The time of this fruit being ripe is in the months of October and November; at which ſeaſon the flowers are blown for the next year's fruit; ſo that from the time of flowering to the ripening of the fruit is one whole year.

The beſt method of propagating theſe trees is by ſowing their ſeeds, which ſhould be preſerved in dry ſand till March; at which time you ſhould ſow them upon a very moderate hot bed, (which greatly promotes their vegetation) covering it about a quarter of an inch with light earth, and ſcreening it from froſts, or great rains. Towards the latter end of April your young plants will appear; you muſt therefore keep them clear from weeds, and give them frequent waterings, as the ſeaſon may require, and ſhade them in hot weather; and if your plants have done well, they will be, by autumn, about five or ſix inches high: but as theſe trees are ſubject to receive damage from froſts, eſpecially while they are young, you muſt hoop the bed over, that, when bad weather comes, you may cover it with mats and ſtraw to keep out the froſt.

The beginning of April following you may tranſplant theſe trees, each into a ſmall pot; but, in doing of this, be very careful to take them up with as much earth to their roots as poſſible; for they are bad rooting plants, and very ſubject to miſcarry on being removed; and it is for this reaſon I adviſe their being put into ſmall pots: for when they have filled the pot with roots, they may be turned out into large pots, or the open ground, without any hazard of their dying.

When you have put your young plants into the ſmall pots, you ſhould plunge them into another very moderate hot-bed, to encourage their taking new root, ſhading them from the ſun in the middle of the day, and giving them water as they may require: in this bed it will be proper to let the pots remain moſt part of the ſummer; for if the pots are taken out, and ſet upon the ground, the ſmallneſs of their ſize will occaſion the earth to dry ſo faſt, that watering will ſcarce preſerve your trees alive; but if they are kept growing all the ſummer, they will be near a foot high by the next autumn: but it will be adviſeable to ſcreen them from the froſt during their continuance in pots, by plunging them into the ground in a warm place, and covering them with mats in bad weather.

When your trees are grown to three or four feet high, you may ſhake them out of the pots into the open ground, where they are to remain: but this ſhould be done in April, that they may have taken good root before the winter, which would be apt to damage them if newly planted. *Miller's Dict.*

ARC, or ARCH. See the article ARCH.

The word is formed from the Latin, *arcus*, a bow.

ARCANUM, a ſecret, generally uſed to imply a remedy, whoſe compoſition is concealed, in order to increaſe its value.

ARCA CORDIS, in anatomy, the ſame with pericardium. See PERICARDIUM.

ARCADIANS, the name of a ſociety of men of letters, who formed themſelves into a body at Rome, in the year 1690, with a deſign to preſerve learning, and carry Italian poetry to perfection.

They took the name of Arcadians partly from the rules of their ſociety, and partly from every new member's aſſuming, on his admiſſion, the name of ſome ſhepherd of ancient Arcadia. Once in four years they elect a preſident, under the title of guardian, appointing him twelve fellows, who decide all affairs of the ſociety. The famous Chriſtina, queen of Sweden, was their firſt patroneſs. They reckon by Olympiads, and celebrate their feſtivals of wit every fourth year.

ARCBOUTANT, in building, an arched buttreſs. See BUTTRESS.

ARCH, in geometry, ſome part of a curve, intercepted between two points.

ARCH *of a Circle* is a part of its circumference.

Equal ARCHES are thoſe which contain the ſame number of degrees, and are cut from the ſame circle.

Similar ARCHES are thoſe which contain the ſame number of degrees, but cut from unequal circles.

Diurnal ARCH, in aſtronomy, is that part of a circle which is deſcribed by any heavenly object between its riſing and ſetting.

Nocturnal ARCH is that part of a circle deſcribed by a heavenly object between its ſetting and riſing. The diurnal and its ſucceeding nocturnal arch are together equal to a whole circle.

ARCH *of Progreſſion*, or *Direction*, is the arch of the zodiac, which a planet appears to paſs over when it moves in conſequentia, or according to the order of the ſigns.

ARCH *of Retrogradation* is an arch of the zodiac deſcribed by a planet, while it is retrograde, or its motion contrary to the order of the ſigns.

ARCH *of Viſion* is an arch of an azimuth circle, intercepted between the center of the ſun, after its ſetting, and the horizon, when a ſtar, before hid in his rays, begins to appear again.

ARCH, in architecture, implies a concave building, erected on a mould bent in the form of a curve, for ſupporting ſome ſtructure.

Arches are either circular, elliptical, or ſtraight, as they are improperly called by workmen.

Circular ARCHES are of three kinds, ſemicircular arches, ſcheme arches, and arches of the third and fourth point.

Semicircular ARCHES are thoſe that have their centers in the middle of the lines drawn from one foot to the other.

Scheme or *Skene* ARCHES are leſs than a ſemicircle, ſome containing ninety, and others only ſeventy degrees.

ARCHES *of the third and fourth Point*, conſiſt of two arches of a circle, meeting in an angle at the top, being drawn from the diviſion of a chord into three or four parts at pleaſure.

Elliptical ARCHES conſiſt of ſemi-ellipſes, and have commonly key-ſtones and impoſts. They are uſually deſcribed by workmen on three centers.

Straight ARCHES are thoſe uſed over doors and windows, having plain ſtraight edges, both above and below, parallel to each other; but both the ends and joints point towards a center.

For the theory of arches, ſee the article BRIDGE.

Triumphal ARCH, a ſtately gate of a ſemicircular form, adorned with ſculpture, inſcriptions, &c. erected in honour of thoſe who have deſerved a triumph.

Mural ARCH. See MURAL *Arch*.

ARCHÆUS. See ARCHEUS.

ARCH-ANGEL, in theology, an intellectual being, or angel of the ſecond order in the celeſtial hierarchy.

The word is compounded of the Greek, αρχος, chief, and αγγελος, an angel.

ARCHANGEL, in botany, a name ſometimes given to the lamium. See LAMIUM.

ARCH-BISHOP, a prelate having ſeveral ſuffragan biſhops under him.

Though biſhops, in the primitive church, were all veſted with the ſame office and authority, yet, as Chriſtianity increaſed, it was found neceſſary to enlarge the epiſcopal power: therefore, as before there was commonly a biſhop placed in every great city, ſo now, in every metropolis, as the Romans called it, or mother-city, of every province, wherein were courts of civil judicature, there was a metropolitan, or archbiſhop, who had eccleſiaſtical juriſdiction over all the biſhops of that province. His juriſdiction conſiſted in ordaining, or ratifying, the elections and ordinations of all other biſhops; and once a year he was to ſummon them all to a ſynod, in which he preſided, to enquire into their conduct, to cenſure with ſuſpenſion, or deprivation, and to hear and determine cauſes between contending biſhops.

Dr. Bingham is of opinion, that archbiſhop was originally but another name for patriarch; though in proceſs of time their juriſdiction became diſtinct.

The firſt eſtabliſhment of archbiſhoprics in England, if we may credit Bede, one of the moſt ancient writers of the Engliſh nation, was, in the time of Lucius, ſaid to be the firſt Chriſtian king of England; who, after the converſion of his ſubjects, erected three archbiſhoprics, in London, York, and Landaff, then called Caerleon. The dignity of archbiſhop continued in the ſee of London 180 years, when it was tranſlated to Canterbury, where it has continued ever ſince. York remains a metropolitical ſee to this day. The archbiſhop of Canterbury is ſtiled "Primate, and Metropolitan of all England;" and the archbiſhop of York, "Primate, and Metropolitan of England."

ARCHBUTLER, one of the great officers of the German empire, who preſents the cup to the emperor on ſolemn occaſions. This office belongs to the king of Bohemia.

ARCHCHAMBERLAIN, an officer of the empire, nearly the ſame with the great chamberlain of England. The elector of Brandenburgh was appointed archchamberlain, by the golden-bull.

ARCHCHANTOR, the preſident of the chantors of a cathedral or collegiate church.

ARCHDEACON, an eccleſiaſtical dignitary, or officer, next to a biſhop, whoſe office extends over part, or ſometimes the whole dioceſe.

There are ſixty archdeacons in England, who viſit the pariſhes ſubject to their juriſdiction, enquire into the repairs of churches, reform abuſes, ſuſpend, excommunicate, &c. They likewiſe, in many places, induct clerks into their benefices.

ARCH-DUKE, a title given to dukes of greater authority and power than other dukes.

ARCHE, among phyſicians, implies the beginning or firſt period of a diſeaſe.

The work is Greek, αρχη, and ſignifies beginning.

ARCHED *Legs*, in horſemanſhip, when the knees of a horſe are bended in the form of an arch. This is reckoned a very great fault, and is often occaſioned by hard travelling.

ARCHER, in the ancient military art, implied a perſon who fought with a bow and arrows.

ARCHES, or *Court of* ARCHES, the ſupreme court belonging to the archbiſhop of Canterbury, to which appeals lie from all the inferior courts within his province.

ARCHETYPE, the firſt or original model of a work, which is copied after to make another like it.

The word is compounded of the Greek, αρχη, beginning, and τυπος, a type.

This term is uſed by minters to ſignify the ſtandard weight by which the others are adjuſted.

ARCHEUS, among chemiſts, implies the predominating principle of things, whereby their peculiar qualities are fixed and determined. Others, however, mean by this term, a certain univerſal ſpirit diffuſed through the whole creation, and which is the active cauſe of all the phœnomena in nature. They even attribute ideas to the archeus, and thence call them archeal ideas.

ARCHIATOR, the chief or principal phyſician of a prince, who retains ſeveral of the faculty.

The word is Greek, αρχιατρος, and compounded of αρχη, chief, and ιατρος, a phyſician.

ARCHIL, *Archilla*, in botany, a whitiſh moſs growing upon rocks in the Canary and Cape Verd Iſlands, and which yields a rich purple tincture, fugitive indeed, but extremely beautiful.

This weed is imported to us as it is gathered: thoſe who prepare it for the uſe of the dyer, grind it betwixt ſtones, ſo as to thoroughly bruiſe, but not reduce it into powder, and then moiſten it occaſionally with a ſtrong ſpirit of urine, or urine itſelf mixed with quick-lime: in a few days it acquires a purpliſh red, and at length a blue colour: in the firſt ſtate it is called archil, in the latter lacmus, or litmaſe.

The dyers rarely employ this drug by itſelf, on account of its dearneſs and the periſhableneſs of its beauty. The chief uſe they make of it is, for giving a bloom to other colours, as pinks, &c. This is effected by paſſing the dyed cloth or ſilk through hot water, lightly impregnated with the archil. The bloom thus communicated ſoon decays upon expoſure to the air. Mr. Hellot informs us, that by the addition of a little ſolution of tin, this drug gives a durable dye; that its colour is at the ſame time changed towards a ſcarlet; and that it is the more permanent, in proportion as it recedes the more from its natural colour.

Prepared archil very readily gives out its colour to water, to volatile ſpirits, and to ſpirit of wine: it is the ſubſtance principally made uſe of for colouring the ſpirits of thermometers. As expoſure to the air deſtroys its colour upon cloth, the excluſion of the air produces a like effect in theſe hermetically ſealed tubes; the ſpirits of large thermometers becoming in the compaſs of a few years colourleſs. M. l'Abbé Nollet obſerves, (in the French Memoirs for the year 1742) that the colourleſs ſpirit, upon breaking the tube, ſoon reſumes its colour, and this for a number of times ſucceſſively; that a watery tincture of archil, included in the tubes of thermometers, loſt its colour in three days; and that in an open deep veſſel it became colourleſs at the bottom, whilſt the upper part retained its colour.

A ſolution of archil in water, applied on cold marble, ſtains it of a beautiful violet or purpliſh-blue colour, far more durable than the colour which it communicates to other bodies.

Mr. du Foy ſays he has ſeen pieces of marble ſtained with it, which in two years had ſuffered inſenſible change. It ſinks deep into the marble, ſometimes above an inch; and at the ſame time ſpreads upon the ſurface, unleſs the edges be bounded by wax, or other like ſubſtances. It ſeems to make the marble ſomewhat more brittle.

Linnæus informs us, in the Swediſh Tranſactions for the year 1742, that the true archil moſs is to be found on the weſtern coaſts of England; and ſuſpects, that there are ſeveral other more common moſſes, from which valuable colours might be extracted: a quantity of ſea-moſs having rotted in heaps upon the ſhore, he obſerved the liquor in the heaps to look like blood, the ſea-water, and the ſun, and the putrefraction, having brought out the colour. Mr. Kalm, in an appendix to Linnæus's paper in the year 1745, mentions two ſorts of moſſes actually employed in ſome parts of Sweden for dying woolen red: one is the *Lichenoides coralliforme apicibus coccineis*, of Ray's Synopſis; the other the *Lichenoides tartareum farinaceum, ſcutellarum umbone fuſco*, of Dillenius. This laſt is a white ſubſtance, like meal clotted together, found on the ſides and tops of hills. It is ſhaved off from the rocks after rain, purified from the ſtony matters intermixed among it by waſhing with water, then dried in the ſun, ground in mills, and again waſhed and dried: it is then put into a veſſel with urine, and ſet by for a month. A little of this tincture, added to boiling water, makes the dying liquor. In the ſame Tranſactions for the year 1754, there is an account of another moſs, which, prepared with urine, gives a beautiful and durable red or violet dye to wool and ſilk. This is the *Lichen foliaceus, umbilicatus, ſubtus lacunoſus linn. flor. Suec.* It grows upon rocks, and is readily diſtinguiſhed from others of that claſs, by its looking as if burnt or parched; conſiſting of leaves as thin as paper, convex all over on the upper ſide, with correſponding cavities underneath, adhering firmly to the ſtones by a little root under the leaves, and coming aſunder, when dry, as ſoon as touched. It is gathered after rain, as it then holds beſt together, and parts eaſieſt from the ſtone.

In France, a cruſtaceous moſs, growing upon rocks in Auvergne, is prepared with lime and urine, and employed by the dyers as a ſuccedaneum to the Canary archil, to which it is ſaid to be very little inferior: it is called orſeille d'Auvergne, or perelle. Mr. Hellot relates, that he has met with ſeveral other moſſes, which, on being prepared in the ſame manner, acquire the ſame colour. The moſt expeditious way, he ſays, of trying whether any moſs will yield an archil or not, is, to moiſten a little of it with a mixture of equal parts of ſpirit of ſal-ammoniac and ſtrong lime-water, and add a ſmall portion of crude ſal-ammoniac; the glaſs is then to be tied over with a piece of bladder, and ſet by for three or four days. If the moſs is of the proper kind, the little liquor which runs from it upon inclining the veſſel, will appear of a deep crimſon colour; and this afterwards evaporating, the plant itſelf acquires the ſame colour. *Lewis's Notes on Neumann's Chemiſtry.*

ARCHILOCHIAN, a term in poetry, applied to a ſpecies of verſe invented by Archilochus.

Theſe verſes conſiſt of ſeven feet, the four firſt of which are ordinary dactyls, though ſometimes ſpondees, and the three laſt trochees. The following verſe from Horace is of this kind:

Solvitur acris hyems grata vice veris et Favoni.

ARCHIMANDRITE, in eccleſiaſtical hiſtory, was a name given by the ancient Chriſtians to what we now call an abbot. Father Simon obſerves, that the word *mandrite* is Syriac, and ſignifies a ſolitary, or monk.

ARCHIPELAGO, in geography, a general name for a ſea interrupted with a great number of iſlands.

The moſt celebrated Archipelago, and that to which the name is in ſome meaſure appropriated, lies in the ſea between the coaſts of Greece, Macedonia, and Aſia.

ARCHISYNAGOGUS, the chief of the ſynagogue; the title of an officer among the Jews, who preſided in their ſynagogues and aſſemblies.

The number of theſe officers was not fixed, nor the ſame in all places; there being ſeventy in ſome, and in others only one. They are ſometimes called princes of the ſynagogue, and had a power of excommunicating ſuch as deſerved that puniſhment.

ARCHITECT, a perſon ſkilled in architecture, who not only draws the plans of edifices, but alſo ſuperintends and directs the artificers.

The word is formed from the Greek, αρχος, principal, and τεκτων, workman.

ARCHITECTONIC, ſomething endowed with the power and ſkill of building, or calculated to aſſiſt the architect.

ARCHITECTURE, the art or ſcience of erecting edifices, either for habitation or defence.

Architecture is doubtleſs of very great antiquity, and was, perhaps, preceded only by agriculture itſelf. Hence Theodoret calls the latter the eldeſt ſiſter of architecture. The exceſſive heats of ſummer, the ſeverity of winter, the inconvenience of rain, and the violence of wind, ſoon inſtructed mankind to ſeek for ſhelter, and provide themſelves with proper retreats to defend themſelves againſt the inclemencies of the weather. But theſe at firſt were only ſmall huts, built very rudely with the branches of trees, and very indifferently covered. In the time of Vitruvius, they ſhewed at Athens, as a curious relic of antiquity, the roof of the Areopagus, made of clay; and at Rome, in the temple of the Capitol, the cottage of Romulus thatched with ſtraw.

After theſe rude eſſays, buildings of wood were introduced, and theſe ſuggeſted the idea of columns and architraves. The columns were modelled from the trees uſed to ſupport the roof, and the architrave from the large beam laid between the columns and the roof.

But, in conſequence of a continual application to building, the workmen became every day more induſtrious and more expert. Inſtead of thoſe ſlight huts, with which they were at firſt contented, they began to erect walls of ſtone and brick upon ſolid foundations, and to cover them with boards and tiles. In proceſs of time, their reflections, founded on experience, led them to diſcover the juſt rules of proportion, ſo natural to man; the great Author of his being having implanted its principles in his ſoul, to make him ſenſible that he is born for order.

It was therefore by degrees that architecture attained the height of perfection to which the maſters of the art have carried it. It was originally confined to the mere neceſſaries and uſes of life, having nothing in view but ſolidity, healthfulneſs, and convenience. Afterwards the architects laboured to adorn their edifices, and called in the other arts to their aſſiſtance.

Moſes tells us that Cain built a city; and hence we learn both the time when, and place where, architecture had its origin. Aſia was therefore the cradle of architecture; there it had its birth, and there it attained a conſiderable degree of perfection; and thence it ſpread into other parts of the world.

Babylon and Nineveh, the largeſt and moſt magnificent cities mentioned in hiſtory, were built by Nimrod, the grandſon of Noah, and the firſt of conquerors. They were not indeed at firſt carried to that prodigious magnificence which afterwards aſtoniſhed the world; but they were certainly very large and extenſive.

The erection of the famous pyramids, the labyrinth, and a prodigious number of temples in Egypt, together with the amazing obeliſks, which are to this day the admiration and ornament of Rome, ſhew with what ardor and ſucceſs the Egyptians applied themſelves to architecture.

This art, however, is neither indebted to Aſia nor Egypt for that degree of perfection it attained; and there is reaſon to doubt whether the buildings of both were not more remarkable for their enormous magnitude, than valuable for their juſtneſs and regularity. But however that be, it appears from the very names of the three principal orders, that the invention, if not the perfection of them, is to be aſcribed to Greece; and that it was ſhe that preſcribed the rules, and ſupplied the models of them. It was in her ſchool that true taſte preſided, and thither we muſt have recourſe, if we deſire to excel.

It is indeed a misfortune that not one ſingle treatiſe written by the Greeks upon architecture, has reached our hands. The only books we have of theirs upon this ſubject, are the ſtructures of thoſe ancient maſters ſtill ſubſiſting, whoſe beauty is univerſally acknowledged, and which have for almoſt two thouſand years been the admiration of all good judges. Theſe ſtructures are ſuperior to all the precepts they could have left us; as practice in every thing infinitely excels theory.

The Romans borrowed the art from the Greeks, and under Auguſtus, when good taſte univerſally prevailed, carried it to a great degree of perfection. But it fell with the weſtern empire, and was not recovered for the ſpace of twelve centuries.

The ravages of the Viſigoths, in the fifth century, deſtroyed moſt of the beautiful monuments of antiquity, and architecture became ſo rude and artleſs, that their profeſſed architects were totally ignorant of juſt deſigning, wherein its whole beauty conſiſts: and hence a new method of building took place, called the Gothic.

Charlemagne did every thing in his power to reſtore architecture; and the French applied themſelves to it with ſucceſs, under the encouragement of Hugh Capet. His ſon Richard purſued the ſame plan; ſo that by degrees the modern architecture became as faulty for its exceſs of delicacy, as the Gothic was before for its maſſineſs.

The architects of the 13th, 14th, and 15th centuries, who had acquired ſo much knowledge in ſculpture, made the perfection of their art to conſiſt wholly in the delicacy and multitude of the ornaments with which they decorated their buildings, with the utmoſt care and ſolicitude, though frequently without either judgment or taſte.

In the two laſt centuries, the architects of Italy, England, and France, employed themſelves wholly in retrieving the primitive ſimplicity and beauty of ancient architecture; and ſo far ſucceeded, that our churches, palaces, &c. are now built after the models of antiquity.

And hence every building is, or ſhould be, proportioned to the bulk, ſtrength, delicacy, richneſs, or ſimplicity deſired; and conſequently a different proportion obſerved in the various members of the edifice. In theſe different proportions conſiſt the five orders of architecture, all invented at different times and on different occaſions. Theſe are called the Tuſcan, Doric, Ionic, Corinthian, and Compoſite. See ORDER.

Architecture is alſo divided into civil, military, and naval.

Civil ARCHITECTURE teaches the method of erecting all kinds of buildings, as palaces, churches, private houſes, &c. and the rules to be obſerved are ſolidity, convenience, and beauty; order, diſpoſition, proportion, decorum, and œconomy. Solidity implies the choice of a good foundation, and ſound materials; convenience conſiſts in ſo ordering the parts of an edifice that they may not embarraſs one another; beauty is that agreeable form and pleaſing appearance which it exhibits to the eye of the ſpectator; order gives every part of the building a convenient bigneſs, whether conſidered alone, or in relation to the whole; and the diſpoſition is the agreeable union of all the parts. Proportion is the relation that all the work has to its parts, and which every one ſeparately hath to the whole; decorum teaches the architect to have a regard to deſign, cuſtom, and nature; and œconomy, to conſider the expence, in order to regulate the form and manner of the fabric.

The only entire piece upon architecture among the ancients is that of Vitruvius: and the moſt celebrated of thoſe who have written on that ſubject ſince his time, are, Baptiſta Alberti, Palladio, Scamozzi, Blondel, Goldman, Perrault, Sir Henry Wotton, Sturmius, and Wolfius.

Military ARCHITECTURE is the ſame with what is generally called fortification. See FORTIFICATION.

Naval ARCHITECTURE is the art of building ſhips. See SHIP BUILDING.

Counterfeit ARCHITECTURE is that which conſiſts of projections, painted either in claro oſcuro, or in colours imitating marble.

ARCHITECTURE *in Perſpective* is a ſort of building, wherein the members are of different modules, and diminiſh proportionally to their diſtance, in order to make the ſtructure appear longer to the view than it really is.

ARCHITRAVE, in architecture, is that part of the order of columns, lying immediately upon the capital. It has its name from repreſenting the principal beam in a timber building.

The word is compounded of the Greek, *αρχος*, chief, or principal; and the Latin, *trabs*, a beam.

This member, when placed over the chimney, is called the mantle-piece, and when over a door or window, the hyperthyron.

ARCHIVAULT, in architecture, implies the inner center of an arch, or a band adorned with mouldings, running over the faces of the arch-ſtones, and bearing upon the impoſts. It has only a ſingle face in the Tuſcan order, two faces crowned in the Doric and Ionic, and the ſame mouldings as the architrave in the Corinthian and Compoſite.

ARCHIVE, or ARCHIVES, an apartment in which the records, charters, and other papers of a ſtate or community are depoſited.

The word is formed from the Latin, *arca*, a cheſt.

ARCHMARSHAL, the grand marſhal of the empire; a dignity belonging to the elector of Saxony.

ARCHON, in antiquity, the chief magiſtrate of Athens, after the aboliſhing of monarchical government. It was alſo an appellation given to ſeveral officers, both civil and religious, under the Greek emperors.

The word is Greek, *αρχον*, and literally ſignifies a governor or commander.

ARCHONTICI, in eccleſiaſtical hiſtory, a ſect of heretics that appeared towards the cloſe of the ſecond century; and were ſo called from their holding that the world was created by angels, whom they called arcontes. They were a branch of the Valentinians.

ARCHPRIOR, a name by which the maſter of the order of the knights-templars was ſometimes called.

ARCHTREASURER, the grand treaſurer of the German empire; a dignity belonging to the duke of Brunſwic, king of Great Britain. It is alſo claimed by the elector palatine.

ARCTIC, in aſtronomy, an epithet applied to the north-pole, and alſo to a ſmall circle of the ſphere parallel to the equator, and 23°. 30′. diſtant from the north-pole. See POLE and SPHERE.

The word is formed from the Greek, *αρκτικος*, which is derived from *αρκτος*, a bear, becauſe of a conſtellation called by us the little bear, the laſt ſtar in the tail whereof points nearly to the north-pole.

ARCTOPHYLAX, in aſtronomy, the name of a conſtellation otherwiſe called Boötes. See BOÖTES.

ARCTURUS, in aſtronomy, a ſtar of the firſt magnitude in the ſkirt of Boötes. Its longitude is 20°. 58′. 2″. of ♎, and its latitude 30°. 57′. 0″. N.

ARCTUS, *αρκτος*, in aſtronomy, the Greek name for the conſtellations called by the Latins *urſa major* and *minor*, and by us, the great and little bear. See URSA *Major* and *Minor*.

ARCUATION, in gardening, the method of raiſing trees by layers, which is done in the following manner:

Strong mother plants or ſtools muſt be planted in a clear border, and in a ſtraight line, about ſix feet aſunder. When theſe have ſhot five or ſix main branches from the root, and as many collateral branches, the former muſt be bent to the ground, and there faſtened. The ſmall branches muſt be covered three inches deep upon the joints, and have a large baſon of earth made round them to hold the water.

About the middle of September they may be opened, and if they have taken root may be immediately removed into the nurſery; but if they have not ſufficiently extended their roots, they muſt be ſuffered to remain till the ſpring, and then tranſplanted.

ARCUATION, in ſurgery, denotes a diſtortion or incurvation of the bones.

ARCUTIO, the name of a machine conſiſting of a board covered with hoops, and uſed, by the nurſes of Florence, to prevent the child from being overlaid. Every nurſe is obliged to lay her child in an arcutio, under pain of excommunication.

ARDASSES, in commerce, the coarſeſt of all the ſilks brought from Perſia.

ARDEA, the heron, in natural hiſtory, a genus of long beaked birds; diſtinguiſhed from all others by having the middle toe of each foot ſerrated, or jagged, with a ſeries of ſcales on its outer ſide.

ARDENT, ſomething hot, or as it were burning.

The word is formed from the Latin, *ardens*, which is derived from *ardeo*, to burn.

ARDENT *Fever*, a violent burning fever. See FEVER.

ARDENT *Spirits*, thoſe diſtilled from fermented vegetables; ſo called becauſe they eaſily take fire and burn.

ARDERS, among huſbandmen, implies the fallowings or plowings of grounds. See FALLOWING.

ARDO VENTRICULI, the cardialgia, or heart-burn. See CARDIALGIA.

AREA, in a general ſenſe, implies any plain ſurface whereon we walk, &c.

The word is Latin, and properly ſignifies a threſhing-floor.

AREA, in geometry, denotes the ſuperficial content of any figure. Thus, if a figure, ex. gr. a field, be in form of a ſquare, and its ſide be 30 feet long, its area is ſaid to be 900 ſquare feet, or it contains 900 little ſquares, each a foot every way.—For the method of finding the areas of figures, ſee each under its reſpective name.

AREA, in aſtronomy, the ſpaces which revolving bodies deſcribe by means of rays drawn to the center of force. Thus, if a body revolving about the center of force S, (plate XV. *fig.* 2.) moves in the orbit AMT, the ſpaces ASM, MSA, are thoſe reſpectively deſcribed by the body when arrived at the points M and A, and are exactly proportional to the times of their deſcription.

AREA, among phyſicians, the ſame with alopecia. See ALOPECIA.

ARECA, the fruit of a ſpecies of palm-tree, growing in the Eaſt-Indies. It is in great requeſt by the natives, who are perſuaded that it ſtrengthens the ſtomach, and carries off every thing that might corrupt the gums.

ARENA, ſand, in natural hiſtory. See SAND.

ARENA, in antiquity, the place where the gladiators, &c. fought; ſo called from its being always covered with ſand, to conceal the blood ſpilt in the combat from the view of the people.

ARENATION, a kind of dry bath, where the patient ſits with his bare feet on hot ſand.

AREOLA, among anatomiſts, the coloured circle ſurrounding the nipple of the breaſt.

AREOPAGUS, or ARÆOPAGUS, in antiquity, a ſovereign court at Athens, ſo famous for the juſtice and impartiality of its decrees, that the gods themſelves are ſaid to have ſubmitted their diſputes to its determination.

ARGEA, or ARGEI, in antiquity, thirty human figures made of ruſhes, and thrown annually by the prieſts or veſtals into the Tiber, on the day of the ides of May.

ARGEMONE, in botany, the thorny Mexican poppy, a genus of plants with roſaceous flowers, and a unilocular capſule for its fruit.

ARGENT, in heraldry, the white colour in the coats of gentlemen, knights, and baronets; the white in the arms of ſovereign princes, being called luna; and that in the arms of the nobility, pearl.

This is expreſſed, in engraving, by the parts being left plain, without any ſtroke from the graver.

ARGENTARIA CRETA, in natural hiſtory, an earth perfectly white and pure, found in Pruſſia, and greatly eſteemed for cleaning plate.

ARGENTINA, in natural hiſtory, the name of a fiſh found in ſeveral parts of the Mediterranean. It reſembles a pike, and has an oblong round body without ſcales. It is of a greeniſh aſh-colour above the lateral lines, but below them of a bright ſhining ſilver colour, eſpecially over the covers of the gills. The ſnout is oblong; the mouth of a moderate ſize, without teeth in the jaws, though there are ſix or eight crooked ones near the end of the tongue. The eyes are large, with a ſilver-coloured iris; and the brain may be ſeen through the ſkull. About the middle of the back is a fin, ſupported by ten rays. The tail is forked; but the principal mark that diſtinguiſhes it from all other fiſh, is the air bladder, which is conical at both ends, and outwardly looks as if covered with poliſhed ſhining leaf ſilver. This is made uſe of to counterfeit pearls. It is often brought to the fiſh markets at Rome.

ARGENTINA, ſilver-weed or wild tanſy, in botany, a low creeping plant, with winged leaves, compoſed of ſeven or eight pair of oblong indented ſegments ſet along a middle rib, with ſmaller portions between, green above, and covered with a ſilver-coloured down underneath: the flowers, which riſe on long pedicles in the boſoms of the leaves, are compoſed each of five gold-coloured petals, with a number of threads in the middle, and followed by a ſmall cluſter of naked ſeeds. It is perennial; common by the ſides of rivulets and in moiſt uncultivated places; and flowers in June.

The leaves of argentina have been generally looked upon as ſtrong aſtringents, and recommended as ſuch in fluxes and hæmorrhages. That they have an aſtringent quality is manifeſt to the taſte, and from their ſtriking a black colour with ſolutions of chalybeate vitriol; but in the leaves in ſubſtance, whether freſh or dry, and in their infuſions, decoctions, and expreſſed juice, the preparations which have been generally made of them, the aſtringency is very weak; and even the extracts made from them, by water and by rectified ſpirit, in which all their active matter is concentrated, are only among the milder ſtyptics or corroborants. The ſpirituous extract is ſtronger than the watery, and in proportionably ſmaller quantity. *Lewis's Hiſtory of the Materia Medica.*

ARGENTUM, ſilver, in natural hiſtory. See SILVER.

ARGILLA, clay. See CLAY.

ARGO, in antiquity, a ſhip or veſſel celebrated among the poets, as being that wherein the Argonauts made their expedition.

ARGO *Navis*, or the ſhip, in aſtronomy, is the name of a conſtellation of fixed ſtars in the ſouthern hemiſphere. The number of ſtars is 8 in Ptolemy's catalogue; in Tycho's 11; and in Mr. Flamſtead's 25.

ARGOL, red tartar. See TARTAR.

ARGONAUTS, in antiquity, a company of illuſtrious Greeks, who embarked with Jaſon, in the ſhip Argo, on an expedition to Colchis, in order to acquire the golden fleece.

ARGUMENT, *Argumentum*, in rhetoric and logic, implies an inference drawn from premiſſes, the truth of which is indiſputable, or at leaſt highly probable.

The arguments of orators have particular denominations, according to the topics whence they are derived: thus we meet with arguments from affection, which intereſt the paſſions of the perſon to whom they are addreſſed; arguments *ad hominem*, or thoſe drawn from the profeſſed principles of the auditor, &c.

The arguments of logicians are the ſyllogiſm, enthymem, induction, &c. See SYLLOGISM, ENTHYMEM, &c.

ARGUMENT, in aſtronomy, implies a known arch, by the aſſiſtance of which we ſeek another unknown.

Thus the argument of the moon's latitude is her diſtance from the node; and the argument of inclination is an arch of a planet's orbit, intercepted between the aſcending node, and the place of the planet from the ſun, numbered according to the order of the ſigns.

ARGUMENT alſo implies the abridgement or heads of a book, chapter, poem, &c.

ARGUMENTATION, the act of arguing; and the manner of framing arguments.

ARGUS, in natural hiſtory, the name of an uncommon ſerpent, found in Guinea; and ſo called from its being covered with ſpots from the head to the tail, reſembling eyes. On the back there is a double row of them, which are the largeſt, and the ground colour of the ſcales is a bright cheſnut, except on the back between the eyes, where it is of a dark brown.

ARGUS is alſo the name of a very curious ſhell, about three inches long, two in diameter, and ſomewhat leſs in height. The mouth is wide, and the lips are continued at each extremity in the form of a broad ſhort beak, each way. The general colour is yellowiſh, only there are three brown bands of a conſiderable breadth running over it; and the whole ſurface is adorned with a multitude of round ſpots, like eyes, from whence it has its name. It is brought from Africa and the Eaſt Indies.

ARIANS, in eccleſiaſtical hiſtory, a ſect of heretics, who followed the opinions of Arius, a preſbyter of Alexandria, in the time of the patriarch Alexander. He broached his hereſy in the beginning of the fourth century.

The Arians denied the three perſons in the holy Trinity to be of the ſame ſubſtance; aſſerted that there was a time when the Son was not; that he was created in time, mutable in nature, and like the angels, liable to ſin; and that being united to human fleſh, he ſupplied the place of a human ſoul, and conſequently was ſubject to ſufferings and pain. In their doxologies they aſcribed "Glory to the Father, through the Son, and in the Holy Ghoſt."

ARIANISM, the doctrine or tenets of the Arians.

ARIDAS, a kind of taffaty, manufactured in the Eaſt Indies, from a ſhining thread drawn from certain plants; and hence they are ſtiled aridas, or herbs.

ARIES, the ram, in aſtronomy, a conſtellation of fixed ſtars, drawn on the globe in the figure of a ram. It is the firſt of the twelve ſigns of the zodiac, from whence a twelfth part of the ecliptic takes its name; and is marked thus ♈.

The number of ſtars in the conſtellation Aries, in Ptolemy's catalogue is 18; in Tycho's 21; and in Mr. Flamſtead's 65.

ARIES, the battering ram. See BATTERING RAM.

ARISH, a Perſian long meaſure, containing about 3197 Engliſh feet.

ARISTA, among botaniſts, a long needle-like beard, which ſtands out from the huſk of a grain of corn, graſs, &c. It is alſo called awn.

ARISTOCRACY, a form of government where the ſupreme power is lodged in the principal perſons of the ſtate, either on account of their nobility, their capacity, or their probity.

The word is Greek, and compounded of αριςος, principal, and κρατεω, to command.

ARISTOLOCHIA, birth-wort, in botany. See BIRTH-WORT.

ARISTOTELIAN, ſomething that relates to the philoſopher Ariſtotle.

ARISTOTELIAN *Philoſophy*, the philoſophy of Ariſtotle, ſometimes called the peripatetic philoſophy.

The philoſopher, from whom the denomination ariſes, was the ſon of Nicomachus, phyſician of Amyntas, king of Macedonia, born in the year of the world 3566; before Chriſt, 348; at Stagira, a town of Macedonia; or as others ſay, of Thrace; whence he is alſo called the Stagyrite.

At ſeventeen years of age he entered himſelf a diſciple of Plato, and attended in the academy till the death of that philoſopher. Repairing afterwards to the court of king Philip, at his return he found that Xenocrates, during his abſence, had put himſelf at the head of the academic ſect; upon which he choſe the Lyceum for the ſcene of his future diſputations.

It being his practice to philoſophize walking, he got the appellation, Peripateticus; whence his followers were alſo called peripatetics. Though others will have him to have been thus named, from his attending on Alexander at his recovery from an illneſs, and diſcourſing with him as he walked about.

Ariſtotle was a perſon of admirable genius, and of great and various learning. Averrhoes makes no ſcruple to call him, "The genius of nature, the limit of human underſtanding;" and declares him "ſent by Providence to teach us all that may be known." He is accuſed of a too immoderate deſire of fame, which led him to deſtroy the writings of all the philoſophers before him, that he might ſtand ſingly, and without competitors. And hence, in the ſchools, Ariſtotle is called, The philoſopher. Laertius, in his life of Ariſtotle, enumerates his books to the number of 4000; of which ſcarce above 20 have ſurvived to our age.

This great philoſopher has been deified by ſome, and deſpiſed by others; but a ſhort view of his works will abundantly convince us, that both theſe extremes are ill founded. His firſt eſſays were on oratory and poetry; which, in all probability, he compoſed for the uſe of his royal pupil, Alexander the Great. Theſe books are maſter-pieces; and his ſtudy of Homer gave him ſo finiſhed a taſte in poetry and rhetoric, that whoever would now ſpeak or write elegantly on thoſe ſubjects, muſt obſerve his precepts; and perhaps theſe performances do moſt honour to his memory.

His ethics are very dry, barren, and unfruitful; offer nothing to us, but general views and metaphyſical propoſitions; fitter to adorn the mind and load the memory, than touch the heart, and correct the will: and this ſpirit prevails in all the moral writings of our philoſopher. A ſketch of his principal doctrines will ſufficiently prove this aſſertion. 1. The happineſs of man, ſays he, conſiſts not in riches, pleaſures, power, nobility, nor philoſophical ſpeculations; but rather in certain habits of the ſoul, which render him more or leſs perfect. 2. Virtue is full of charms; conſequently a virtuous life muſt be happy. 3. Though virtue be ſufficient of itſelf, yet it cannot be denied, but that riches, honours, a noble birth, beauty of body, and things of this nature, greatly contribute to advance the happineſs of man. 4. Every virtue keeps the mean betwixt two extremes: thus courage is the mean betwixt fear and raſhneſs; liberality, betwixt avarice and extravagance, &c. from whence we may conclude, that the number of vices are twice the number of virtues; becauſe every virtue has on each ſide an oppoſite vice. 5. He diſtinguiſhes two ſorts of juſtice; the one he calls univerſal, the other particular. Univerſal juſtice tends to the preſervation of civil ſociety, by the reſpect and obedience it inſpires and injoins for the laws. Particular juſtice conſiſts in rendering every man his due; and is of two ſorts, diſtributive and communicative. Diſtributive juſtice diſpenſes rewards and puniſhments to every citizen, according to his merit, and is founded on a geometrical proportion. Communicative juſtice has commerce for its object; conſiſts in rendering to every man his due; and muſt proceed according to arithmetical proportion. 6. Friendſhip ariſes either from the pleaſure we find in a perſon's converſation, the profit which may reſult from it, or from the merit of ſome eminent qualities, founded on the virtue we diſcover in the object: this laſt is true friendſhip; benevolence, properly ſpeaking, is not friendſhip, though it leads to it.

Ariſtotle has ſucceeded much better in his logic than in his ethics. His logic diſcovers all the principal ſprings of the art of reaſoning; he deſcends ſoon to the thoughts of man; diſtinguiſhes his ideas; ſhews their connection; purſues them through all their deviations and ſeeming contrarieties; and at laſt reduces them to a fixed point. If the extent of the mind could have been known, Ariſtotle would certainly have diſcovered it. Is it not ſurpriſing that, by the different combinations he has made of all the forms the mind can put on in reaſoning, he has confined it in ſuch a manner, by the rules he has laid down, that it can never deviate from its object, nor reaſon abſurdly? But this method, though ſo much extolled by all philoſophers, is not free from faults. 1. He is too prolix; all his books of categories might be reduced to a few pages; the ſenſe is drowned in a ſuperfluity of words. 2. He is obſcure and intricate; he expects you to gueſs at his meaning; would have his reader, like himſelf, know what he intended. A man of the beſt capacity muſt often deſpair of having fully underſtood him in his doctrine of the analyſis and ſyllogiſm.

Let us now conſider Ariſtotle's natural philoſophy; and here we ſhall principally follow the famous Lewis Viſis, who has proceeded very methodically on the ſubject, by taking notice of all this philoſopher's phyſical works; he begins with his eight books of Natural Principles; which ſeem rather ſo many different memoirs, than a book wrote on one and the ſame plan. Theſe eight books treat of bodies extended in general, which is the object of phyſics; and, in particular, of the principles of bodies, and all that is connected with theſe principles, as motion, place, time, &c. Nothing is more confuſed than the long detail he gives us; his definitions render things, clear and evident in themſelves, obſcure and unintelligible. Ariſtotle begins with condemning all the philoſophers who went before him, and even in very harſh terms, for having admitted only one principle. With regard to himſelf, he lays down three principles, which are matter, form, and privation. Matter, according to him, is the general ſubject on which nature operates: this matter is eternal; the parent of all things; which eagerly longs for motion, and deſires to be united to form. Ariſtotle's definition of his firſt matter is a kind of jargon; he defines it in theſe terms: "That which "has neither quality or quantity, or any thing by which "its being can be determined." If he only means, according to his method of conſidering things, firſt in a general view, and afterwards deſcending to particulars, that this firſt matter had no other foundation than his own conception, nor exiſtence, but in an arrangement of ideas, to reaſon on the ſubject, it may be granted him: but then this firſt matter is an imaginary being, a mere abſtract idea, which exiſts no more in general than a flower, or man, which are but parts of the univerſe. Some are of opinion Ariſtotle meant, by his firſt matter, not only body in general, but a certain uniform paſte, which, like yielding wax, took any impreſſion; out of which all things were formed, and into which they return at their diſſolution; that all bodies were the ſame, and differed only with reſpect to their figure, quantity, motion, or reſt, which are all accidents. This opinion, which owes its origin to Ariſtotle, appeared ſo ſpecious to all philoſophers, both ancient and modern, that it has been generally adopted; though nothing can be more falſe, as is abundantly proved by experiments; for, in conſequence of this doctrine, if motion produced out of this firſt matter, this original paſte or wax, an animal, a tree, or a maſs of gold; take away this motion, the animal, the tree, the gold, muſt return to their primeval paſte; Empedocles, Plato, Ariſtotle, and the ſchoolmen, aſſert this: but it is falſe. The organized body, on its diſſolution, ſeparates into different maſſes, ſkin, hair, fleſh, bone, &c. The mixed body reſolves itſelf into water, ſand, ſalt, and earth: but the moſt powerful diſſolvents, and the hotteſt fire, can never produce any change in theſe ſimple bodies. Sand remains ſand, iron remains iron; gold purified, ſuffers no change; the caput mortuum will always remain a caput mortuum, though tried and tortured a thouſand ways. Chemical experiments have proved this paſt all doubt: we can go no further, the ſeparate elements are permanent, and incapable of change; for this reaſon, that the univerſe, which is compoſed of them, may receive different forms, by their being blended together; and yet be durable, as the principles which form its baſis. As to form, Ariſtotle's ſecond principle, he looks on it as a ſubſtance, an active, conſtituent principle of bodies, which operates on matter. It follows from this poſition, that there muſt be as many natural forms, which are born, and die by turns, as there are primitive and elementary bodies. As to privation, ſays Ariſtotle, it is not a ſubſtance; it is even, in ſome reſpects, a ſort of nothing; in ſhort, bodies which receive ſuch a form, are ſuch as could never have made that form before, but muſt even have had one abſolutely contrary to it. Thus the dead and living are directly oppoſite.

Theſe three principles premiſed, Ariſtotle proceeds to the explanation of cauſes, which he treats of diſtinctly enough; but almoſt always without mentioning the firſt cauſe, which is God. Some have taken occaſion from hence to accuſe him of atheiſm; but we are of a different opinion. Ariſtotle aſſerts, nature is an effective principle, a plenary cauſe, which renders all bodies, wherein it reſides, capable of motion or reſt in themſelves: all bodies which have this power, that cannot in one ſenſe be annihilated, and this tendency to motion, which is always equal, are properly called ſubſtances. Nature, conſequently, is another principle of Ariſtotle; and nature is a term by which he could mean nothing but the Deity; wherefore he did not miſtake the firſt cauſe; but his commentators puzzled themſelves, and the ſchoolmen ran into ſo many abſurdities, by miſunderſtanding him.

After having explained the efficient cauſe of all power diſtributed throughout the univerſe, Ariſtotle proceeds to define motion; but though the efforts of a great genius are conſpicuous, his definition is very lame and imperfect. The farther he advances, his reaſoning becomes more clear; finite and infinite, the vacuum and atoms, ſpace and time, place and the bodies contained in it, preſent themſelves to his view; he makes no confuſion; one propoſition leads to another; and, though the progreſs be extremely rapid, the connection is very plain.

The doctrine contained in his two books of generation and corruption, neceſſarily depends on his principles which we have already explained. Before Socrates, the prevailing opinion was, that nothing abſolutely died or periſhed, but ſomething was again produced from it;

that all the changes which happen in bodies were only another arrangement, a different diſtribution of the parts of matter which compoſed theſe ſame bodies: they aſſerted, that increaſe and diminution, diviſion and re-union, ſeparation and mixture, accounted for all the changes viſible in the univerſe. Ariſtotle rejected all theſe notions, though very ſimple in themſelves, and therefore probable; and eſtabliſhed the doctrine of generation and corruption, properly ſo called. He obſerved new beings produced from the womb of nature continually, which periſhed in their turns. Two things led him into this way of thinking: 1. He imagined the matter of all bodies the ſame; that they only differed in form, which he looked on as their eſſence. 2. This doctrine of privation teaches, that contraries are produced by their contraries, as white by black; whence it follows, that white muſt be annihilated before black can ſucceed. To clear up this ſyſtem, we ſhall make two remarks: 1. That generation and corruption have no connection with the other modifications of bodies, as increaſe, decreaſe, tranſparence, conſiſtence, &c. under all theſe modifications. The firſt form is not effaced, though infinitely diverſified. The ſecond remark, which naturally reſults from the firſt, is, that, as all the diverſity of nature conſiſts in generation and corruption, ſimple and primitive beings only can be ſubject to them; all other bodies are only mixtures, and various combinations of theſe firſt. Though nothing can be more chimerical than this part of Ariſtotle's ſyſtem; yet it has perplexed the ſchoolmen, who have multiplied a number of nonſenſical terms, ſuch as *forma ſubſtantialis*, *modalitas*, *&c.* and continually diſputed about it, without any meaning.

Ariſtotle does not content himſelf with exhibiting a general theory in phyſics, but deſcends to particulars; his meteorology is held by father Rapin to be more clear than all that has been advanced by the moderns on the ſubject. It indeed muſt be owned he accounts for rain, hail, dew, &c. in an extraordinary manner, conſidering his ignorance of the experiments the moderns have made, and ſome diſcoveries, owing to time and chance. His account of the rainbow is ingenious, and really differs but little from that of Deſcartes. His definition of the wind is this, that it is a current of the air; and he ſhews, that its direction depends on an infinity of cauſes, extraneous and little known; which, ſays he, hinders me from giving a general ſyſtem of it. With regard to his hiſtory of animals, it will be ſufficient to ſay, it is highly approved of by M. de Buffon.

Thus we have given ſome account of all his works. Let us now take a ſhort view of his doctrines. The matter, according to Ariſtotle, which compoſes all bodies is the ſame, and only owes its different forms to the different combination of its parts. He admits of four elements, fire, air, water, and earth; which, according to him, are ſufficient to form all ſublunary bodies; but the beauty of the heavens made him ſuſpect them to be formed of finer materials; and, therefore, he ſuppoſed a ſort of fifth element, the quinteſſence of the other four, for the conſtruction of the heavens: and, perhaps, when he had invented a new word, thought, like ſome moderns, he had made a diſcovery of ſomething new; and that what ſubſiſted in his imagination, muſt conſequently alſo ſubſiſt in the univerſe. But neither the authority of Ariſtotle, or any other philoſopher, nor the pretended evidence of their arguments, can convince us of the reality of what they imagined. From theſe five principles, fire, air, water, earth, and a quinteſſence of theſe, Ariſtotle ſuppoſed the whole univerſe to be formed. Of this quinteſſence, or fifth body, being, or eſſence, for (literally the term ſignifies no more, though taken in a metaphorical acceptance, it is generally underſtood to convey another idea) he ſuppoſes the celeſtial bodies formed; and to this he aſcribes a circular motion. To the four elements, of which he ſuppoſes all ſublunary bodies compoſed, he aſſigns only a rectilinear motion. The fifth eſſence has neither gravity nor levity, is incorruptible and eternal; always continues an equal and uniform motion; whereas, of the four elements, two deſcend and gravitate towards the centre, two aſcend and ſeek the circumference; yet they may change their places, and indeed often do ſo, becauſe of the facility they have of transforming themſelves by rarefaction, condenſation, &c.

This premiſed, Ariſtotle aſſerts the univerſe is not equally under the government of God: notwithſtanding he is the general cauſe of all, the celeſtial bodies only are worthy his care and attention; but the earth and ſublunary beings are below his notice. Diogenes Laertius tells us, it was the opinion of Ariſtole, that the heavenly bodies were regulated by the Deity; that the earth and ſublunary beings were governed by a kind of ſympathy with the celeſtial bodies, and influenced by them. This chain of reaſoning infers the mortality of the ſoul, and excludes free agency. A prevailing notion among all the ancient philoſophers, that the ſoul was a particle of the Divine Being, and ſhould return to the Being from whence it proceeded after certain revolutions, contributed not a little to confirm Ariſtotle in this notion.

The falſe ideas this philoſopher had conceived of motion, had led him into an opinion that the world was eternal. Motion, ſays he, muſt have been eternal, conſequently the world wherein it ſubſiſts muſt have been ſo too.

We have now ſeen enough of the doctrine of Ariſtotle to be convinced he is no more to be charged with atheiſm than almoſt all the other ancient philoſophers, who were infected with the ſame errors. Ariſtotle repreſents God as an immaterial and intelligent Being, the firſt mover of all things, who could not be moved himſelf: ſhould it be aſked, what can be thought of Ariſtotle's creation? The anſwer is eaſy; for he admits, if there had been nothing in the univerſe but matter, it could not have been formed without ſome original firſt cauſe. This plainly infers a Deity, and wipes off the imputation of atheiſm, which ſome would have fixed on him. He only differs in opinion from his maſter Plato in this; Ariſtotle thought the world a natural and powerful emanation from the Deity, like light from the ſun; whereas Plato thought the world was not an eternal and neceſſary, but voluntary and deliberate choice of the Deity. The doctrine of the creation in both makes the world eternal, and is very different from that of Moſes, in which God is left ſo free with regard to creating the world, that he might have left it eternally in its original chaos.

But if Ariſtotle be acquitted of atheiſm, becauſe he admits a firſt cauſe, and makes God the author and firſt mover of all things; yet his notions tend directly to ſubvert and deſtroy the liberty of his agency; becauſe, ſays he, motion impreſſed on matter did not proceed from his will, but the neceſſity of his nature; ſo that his god is diveſted of all the attributes we juſtly aſcribe to the Divine Being. Notwithſtanding theſe abſurdities, which ſtrike at the root of the Chriſtian religion, ſome eminent men of the Romiſh perſuaſion have been ſo prejudiced in favour of his philoſophy, that his picture has been drawn in the ſame piece of painting with that of the Saviour of mankind: nay, have been wicked and weak enough to place his writings on the level of holy writ. In latter ages, even after the revival of learning in Italy, ſome have not ſcrupled to place him among the number of the bleſſed. We have two books, yet extant, written expreſsly on this ſubject; one intitled, "The ſalvation of Ariſtotle," which the divines of Cologne are ſaid to have publiſhed; the other, by Lambert Dumont, profeſſor of philoſophy, intitled, "What may moſt probably be advanced concerning the ſalvation of Ariſtotle, drawn from the proofs of Holy Scripture, and borrowed from the teſtimonies of the foundeſt body of divines." Strange infatuation!

We cannot conclude this article, without giving an abſtract of the ingenious parallel father Rapin has drawn between Ariſtotle and Plato. They both, ſays he, poſſeſſed an uncommon and elevated genius. The mind of Plato was, it is true, more refined, but Ariſtotle's more penetrating and profound. Plato's imagination is lively, copious, fruitful in invention, idea, and expreſſion: he gives every ſubject he treats of a thouſand different turns, ſets it in a thouſand lights, and all are pleaſing: but, after all, this is nothing but imagination. Ariſtotle is crabbed and dry, but what he ſays, carries the force of reaſon with it. His diction, though pure, is harſh, and his natural or affected obſcurities perplex and tire his readers. Plato has a delicacy in his thought and expreſſion ; Ariſtotle ſeems to avoid this, in order to be more natural : his ſtile is ſimple and even, but cloſe and nervous : that of Plato pompous and elevated, but looſe and diffuſive. In ſhort, Plato's principal intention ſeems to have been elegance of diction : Ariſtotle's ſolid reaſoning.

Of the Reſtorers of the ARISTOTELIAN *Philoſophy.*—Perhaps philoſophy was never ſo much cultivated as under the Roman emperors ; yet the hiſtory of thoſe times ſufficiently demonſtrate, that it by no means made ſo great a progreſs as might have been expected from the encouragement it received. An inundation of Barbarians deſtroyed the Roman empire, and philoſophy became the companion of its fall. Ignorance ſucceeded, and the only ſtudy in repute, for ſome time, was a kind of logic, that conſiſted in ſubtilties and diſtinctions which ſignified nothing. On the revival of learning, ſome men of letters undertook to oblige the world with a correct tranſlation of Ariſtotle's works into Latin ; former tranſlators had given his diſciples a mean opinion of this great philoſopher, and had rather exhibited their own Gothic taſte than Ariſtotle's genius. But the reſtoration of learning was too great a work for perſons in a private ſtation ; princes therefore intereſted themſelves in it, procured manuſcripts out of the Eaſt, and cauſed them to be tranſlated and publiſhed. Pope Paul V. acquired immortal honour by the encouragement he gave to all undertakings of this kind. He was paſſionately fond of literature in general, and of Ariſtotle's philoſophy in particular. Men of learning increaſed, and conſequently tranſlations. Averrhoes, till then, had been thought Ariſtotle's beſt commentator, but, as learning improved, taſte refined ; they thought Averrhoes retained ſomewhat of barbariſm, and therefore choſe Alexander to explain Ariſtotle in the Lyceum, as a man of more elegance and politeneſs. Averrhoes and Alexander were without compariſon the moſt eminent in the Peripatetic philoſophy ; but their opinions with regard to the ſoul were not orthodox : for Alexander thought it mortal, and Averrhoes, though he acknowledged the ſoul immortal, yet meant only an univerſal ſoul, of which all men partook. Theſe opinions ſpread greatly in the time of Thomas Aquinas, who refuted them very fully. The ſect of Averrhoes, however, prevailed ſo much in Italy, that pope Leo X. thought proper to put a ſtop to the propagation of doctrines ſo oppoſite to Chriſtianity, and condemned the opinion of Averrhoes as impious, in the ſecond Lateran council. Some profeſſors thinking the fulminations of the church inſufficient to make men of learning lay aſide theſe dangerous opinions, oppoſed the Platonic philoſophy as the beſt remedy to this growing evil : ſome, finding many beauties in the philoſophy of Ariſtotle, and highly reverencing the doctrines of the Goſpel, were for reconciling him with Plato ; and others ſoftened the expreſſions of Ariſtotle, and gave them a religious turn.—It may not be diſagreeable to mention ſome of thoſe who diſtinguiſhed themſelves in thoſe controverſies.

Among the Greeks who left their own country, and came to tranſplant learning into Italy, Theodorus Gaza was one of the moſt eminent ; he underſtood the opinions of every ſect of philoſophy, was a great phyſician, a profound divine, and remarkable for his ſkill in polite literature. He was a native of Theſſalonica ; but the victorious arms of Amurath having ravaged all the Eaſt, obliged him to ſeek refuge in Italy. Cardinal Beſſarion received him with friendſhip, and gave him prieſt's orders. He tranſlated Ariſtotle's Hiſtory of Animals, and the Problems of Theophraſtus on Plants. His tranſlations ſo highly pleaſed the cardinal, that he boaſted of them as equal to the original. But though he is eſteemed one of the beſt tranſlators ; yet, as Eraſmus juſtly obſerves, his Latin phraſe has a tincture of Greek, and his opinions the tincture of the age he lived in. Coſmo of Medicis joined with cardinal Beſſarion in ſerving Theodorus, and advancing his fortune ; but Greek and Brutian ſycophants, together with his own want of œconomy, reduced him to extreme poverty : under theſe circumſtances he ſet about a new tranſlation of Ariſtotle's Animal Hiſtory, which he dedicated to Sixtus IV. from whom he only received a preſent of a hundred piſtoles, which he threw with indignation into the Tiber, and withdrew himſelf from Rome into the country of the Brutii, where he would have ſtarved, had not the duke of Ferrara taken notice of him. He died of vexation ſoon after ; a remarkable example of the changes of fortune.

George of Trebizond, as well as Gaza, applied himſelf to the Peripatetic philoſophy ; gave himſelf this title, becauſe it was the country of his anceſtors, for he was a Cretan by birth. He went into Italy, while the council ſat about reuniting the Latin and Greek churches. He was at Venice firſt, from whence he went to Rome, where he taught rhetoric and philoſophy. He was ſo zealouſly fond of Ariſtotle as to defend him in every particular : and wrote the bittereſt invectives againſt the followers of Plato, which created him many enemies. Nicholas V. his patron, notwithſtanding his inclination to the Ariſtotelian philoſophy, diſapproved of his conduct. Cardinal Beſſarion was the moſt powerful antagoniſt that took up the pen againſt him ; he refuted him under the title of the ſlanderer of Plato : but he had a more formidable enemy than the cardinal, neceſſitous poverty ; for this diſpute unhappily deprived him of all ſupport. Poſterity will more eaſily pardon his prejudices againſt the followers of Plato in his age, than the incorrectneſs of his verſions. His tranſlations of the Laws of Plato, and Ariſtotle's Hiſtory of Animals, are deficient in many reſpects ; inattention, want of erudition, and honeſty, are too frequently evident : for he took the liberty of altering the text, leaving out many things of conſequence, and changing others ; as may be ſeen by the tranſlation Euſebius has given us. Thus we ſee, on the revival of learning, men of letters were divided between Plato and Ariſtotle ; both ſides caſt the ſevereſt reflections on each other, which is the caſe of all parties ; but neither are to be regarded more than reaſon decides in their favour.

The Ariſtotelian philoſophy, however, continued in vogue till Des Cartes demoliſhed it ; though he did not ſubſtitute any thing more rational in its ſtead.

ARISTOTELIAN *Wheel, rota Ariſtotelica.* See ROTA.

ARITHMETIC, the art or ſcience of computing by numbers.

The word is Greek, *αριθμετικη*, and derived from *αϱιθμος*, number.

We have very little intelligence with regard to the invention of this ineſtimable ſcience ; hiſtory being ſilent both with regard to the author and fixing the time. Some attribute it to Seth, others to Noah, and the Turks to Enoch, whom they call Edris. Many imagine it had its riſe with the introduction of commerce, and conſequently fix its epocha with that of the Tyrians, who did not begin to flouriſh till about a thouſand years after the flood. Joſephus tells us, that Abraham taught the Egyptians arithmetic during the time of his ſojourning in their country : though Pliny and Strabo ſay, that the inundations of the Nile gave occaſion to their inventing both arithmetic and geometry. But however that be, it is certain both theſe ſciences were held in the higheſt veneration, and committed to the care of their prieſts, who founded their theology on them.

The Greeks owed their knowledge in arithmetic to the Egyptians ; and Pythagoras built his philoſophical ſyſtem upon numbers, affirming that the nature of numbers extends through the whole univerſe, and that the knowledge of numbers is the knowledge of the Deity.

The ancient arithmetic, however, fell far ſhort of the modern ; their notation was very imperfect, and conſequently the operations abſtruſe and tedious. They wanted the cypher, or a character that of itſelf ſignifies nothing, to fill up a place, and change the value of their numbers in a decuple progreſſion, their ſeries extending only to nine.

We owe our preſent notation to the genius of the eaſtern nations, and received it from the Arabians, who learned it from the Indians. But when or by whom it was invented cannot be known. It was known in Europe before the year 1000, and in Britain before 1150.

The oldeſt treatiſe extant on the theory of arithmetic is the 7th, 8th, and 9th books of Euclid's Elements ; where he has delivered the doctrine of proportion, and that of prime and compoſite numbers. The next of whom we know any thing, is Nicomachus the Pythagorean, who wrote a treatiſe on the theory of arithmetic, conſiſting chiefly of the diſtinctions and diviſions of numbers, into certain kinds and claſſes, as plain and ſolid, triangular, quadrangular, and the reſt of the ſpecies of figurate numbers. The arithmetic of Nicomachus was publiſhed at Paris in the year 1538. Boethius the philoſopher, who lived at Rome in the time of Theodoric the Goth, is the next remarkable writer on this ſubject. He is ſuppoſed to have ſeen and copied moſt of his work from Nicomachus.

After the Arabian notation was known in Europe, we find many writers both upon the theory and practice; the firſt conſiderable author is Jordanus of Namur, who flouriſhed about the year 1200. His arithmetic was publiſhed and demonſtrated by Johannes Faber Stapulenſis, in the fifteenth century, ſoon after the invention of printing.

As learning advanced in Europe, ſo did the knowledge of numbers, which by degrees received great improvements: but it would be impoſſible to trace out every ſtep of theſe improvements. In Italy were Lucas de Burgo, and Nicholas Tartaglia; in France, Clavius and Ramus; in Germany, Stifelius and Heniſchius; in England, Buckley, Diggs, and Record. All theſe, and many others, flouriſhed before the year 1600; ſince that time our writers are almoſt innumerable; but the moſt complete treatiſe upon this ſubject is that of the ingenious Mr. Malcolm, which appeared in the year 1730.

The fundamental rules of arithmetic are four, namely, addition, ſubtraction, multiplication, and diviſion. See each under its proper article.

But beſides theſe, there are other rules contrived for facilitating computations of every kind: as the rule of proportion, rule of three, or golden rule, the rules of fellowſhip, barter, exchange, intereſt, extraction of roots, &c. which the reader will find under the ſeveral heads of PROPORTION, FELLOWSHIP, INTEREST, &c.

Binary ARITHMETIC. See BINARY.

Common ARITHMETIC, comprehends, beſides the doctrine of integers, that of broken numbers, or fractions. See FRACTION.

Decadal ARITHMETIC, the ſame with common arithmetic, or that performed by nine figures and a cypher.

Decimal ARITHMETIC, the doctrine of decimal fractions. See DECIMAL.

Dyadic ARITHMETIC, the ſame with binary arithmetic. See BINARY.

ARITHMETIC *of Infinites*, the doctrine of infinite ſeries. See the article SERIES.

Inſtrumental ARITHMETIC, that performed by means of inſtruments, as rules, ſcales, Napier's bones, &c.

Literal or *Specious* ARITHMETIC, that performed by the letters of the alphabet. See ALGEBRA.

Logiſtical or *Sexageſimal* ARITHMETIC, the doctrine of ſexageſimal fractions. See SEXAGESIMAL.

Univerſal ARITHMETIC, a name given by Sir Iſaac Newton to algebra, or the calculation of quantities in general. Nor did that great man, whoſe elevated genius and profound penetration ſeem to have traced all the ſciences to their true metaphyſical principles, give it this title without ſufficient reaſon.

Common arithmetic has two kinds of principles; the firſt are general rules, independent of the characters made uſe of to expreſs numbers; the ſecond are rules which depend on theſe characters, and are properly called rules of arithmetic. The former contain only the general properties of proportions, and take place univerſally, be theſe proportions ſtated how they will.

Hence it follows, that by noting numbers by general expreſſions, though they do not denote one number more than another, we may form certain rules relative to operations, which may be performed by numbers ſo expreſſed. Theſe rules ſhew the reſult of one or more operations performed by numbers expreſſed in a general manner, and in the moſt ſimple method; and this reſult is properly nothing more than an arithmetical operation, expreſſed in characters, which will vary according to the different arithmetical values we aſſign the quantities ſubſtituted for numbers.

In order to ſet this idea of algebra in a clearer light, it may not be amiſs to mention, in a curſory manner, the four common rules of arithmetic. Addition conſiſts in adding any numbers propoſed into one total, without any other operation. If, for example, it were required to add two diſſimilar quantities together, as a and b, we ſet them down ſimply $a+b$, the reſult of which is nothing more than an indication, that if a repreſents a certain number, and b another, theſe numbers muſt be added together. The expreſſion $a+b$ is therefore nothing more than an indication of an arithmetical addition, the ſum of which will be different, according to the different arithmetical values aſſigned to a and b. Suppoſe it were required to add $5a$ to $3a$, we may write $5a+3a$; but it is plain that this may be expreſſed in a more ſimple manner; viz. $8a$; and conſequently the arithmetical operation ſhould be expreſſed in that manner.

Hence it follows, that addition in algebra expreſſes the ſum or aggregate of ſeveral numbers, generally in the moſt ſimple manner, and ſaves the arithmetician as much labour as poſſible.

In ſubtraction, the thing is the ſame; for if it be required to ſubtract b from a, we write $a-b$; becauſe it is impoſſible to expreſs this operation in a more ſimple manner: but ſhould it be required to ſubtract $3a$ from $5a$, it would be improper to write $5a-3a$; becauſe, if a had any numerical value, it would occaſion the trouble of ſeveral arithmetical operations; but ſimply $2a$, which is more convenient in calculation.

The ſame thing is true in multiplication and diviſion. If we would multiply $a+b$, by $c+d$, we might write indifferently $\overline{a+b}\times\overline{c+d}$, or $ac+bc+ad+bd$; though the firſt method ſeems the more proper, becauſe it requires fewer arithmetical operations: in the former there are only two additions and one multiplication neceſſary; in the latter, three additions and four multiplications. But if it ſhould be required to multiply $5a$ by $3a$, we ſhould write $15a$, and not $5a\times3a$; becauſe the firſt has only two arithmetical operations, and the ſecond three. In the ſame manner, to multiply $a+b$ by $a-b$, we ſhould write $aa-bb$; becauſe this reſult would be more commodious than $aa+ab-ab-bb$, and at the ſame time furniſhes a uſeful theorem, namely, that the product reſulting from the ſum of two numbers, multiplied by the difference of the ſame numbers, is equal to the difference of their ſquares.

In diviſion, inſtead of writing $\frac{20ab}{5b}$, we ſhould ſet down ſimply $4a$; but to expreſs the diviſion of ab by cd, we muſt write $\frac{ab}{cd}$; becauſe a more ſimple expreſſion cannot be found.

Hence it is evident that Sir Iſaac Newton was in the right to call algebra univerſal arithmetic; becauſe it exhibits all the general and common rules of every kind of arithmetic, in a more clear, conciſe, and ſimple method.

But it may be aſked, why we ſhould have recourſe to perplexity? In all arithmetical queſtions the numbers are expreſſed; of what uſe therefore can it be to give them a literal expreſſion?

The anſwer is very eaſy: there are queſtions far more complicated; and in the ſolution of theſe we are obliged to form combinations, of which the number or numbers ſought muſt form a part. We muſt therefore be poſſeſſed of an art, whereby we may repreſent theſe combinations without knowing the number ſought; and conſequently expreſs the numbers by characters not numerical: becauſe it would be very improper and inconvenient to expreſs an unknown number by a numerical character, which we had no reaſon to expect would be its real value.

ARITHMETICAL, ſomething belonging to, or performed by arithmetic.

ARITHMETICAL *Complement of a Logarithm, Sine, Tangent, &c.* the ſum or number which a logarithm, &c. wants of 10,000000.

ARITHMETICAL *Mean*. See MEAN.

ARITHMETICAL *Progreſſion*. See the article PROGRESSION.

ARITHMOMANCY, a ſpecies of divination performed by numbers.

The word is Greek, *αριθμομαντεια*, and compounded of *αριθμος*, number, and *μαντεια*, divination.

ARK, ARC, or ARCH. See the article ARCH.

ARK, in the ſcripture language, implies a kind of veſſel, made by the command of God himſelf, for preſerving Noah and his family, together with the ſeveral ſpecies of animals, from the univerſal deluge.

The word is formed from the Latin, *arca*, which ſignifies a coffer.

The ancients inform us, that the Egyptians uſed barks made of bulruſhes on the Nile; and that theſe barks were of an oblong ſquare figure, and ſo light as to be carried by a ſingle man.

There is all the reaſon in the world to think that Noah's ark was made in the form of theſe Egyptian boats, but of an infinitely larger ſize. If we reckon the Hebrew cubit at 20 inches and a half, Engliſh meaſure, the length of the ark muſt have been 512 feet 6 inches; its breadth, 85 feet 5 inches; its height 51 feet 3 inches; and its whole capacity, or hollow part of the ark, 229822 feet 4 inches nearly. The covering of the ark had doubtleſs ſomething of a declivity, in order to carry off the water that fell upon it. The height of it might be divided into four ſtories, allowing three cubits and a half to the firſt, ſeven to the ſecond, eight to the third, and five and an half to the fourth, and leaving the remaining five cubits of the thirty in height for the thickneſs from top to bottom, and the three bridges or floors of the three laſt ſtories.

The firſt of theſe ſtories might be the bottom, or what is called the keel of ſhips. The ſecond might be uſed for a granary or magazine. The third might contain the ſtables; and the fourth, places for the fowls. But, the keel not being reckoned as a ſtory, and ſerving only for a conſervatory of freſh water, Moſes ſays, that there were but three ſtories in the ark, and if interpreters ſet down four, they include the keel. In the ſtables, the four-footed beaſts were lodged, and in the voleries, the birds: ſome reckon as many ſtables or ſtalls as there were ſorts of beaſts, which is not at all neceſſary; becauſe there are many kinds of birds and beaſts which uſe the ſame food, and therefore may live very well together.

The number of beaſts which muſt have entered into the ark, is not ſo great as might be imagined. We are not acquainted with above an hundred and thirty ſpecies of four-footed beaſts; nor do we know of a greater number of birds; and with regard to reptiles not more than thirty ſpecies. We know only ſix ſpecies of beaſts larger than an horſe. There are very few equal to this creature, and many much leſs, and which are under the ſize even of ſheep: ſo that all the four-footed beaſts, including three thouſand ſix hundred and fifty ſheep, which may be ſuppoſed neceſſary for the nouriſhment of ſuch animals as live on fleſh, take up ſcarce any more room than an hundred and twenty oxen, three thouſand ſeven hundred and thirty ſheep, and fourſcore wolves.

Of birds or fowls few are larger than the ſwan, and almoſt all are leſs.

As for reptiles, or creeping animals, their number is not great. They generally are ſmall. Many of them can live in water, and conſequently it was unneceſſary to bring them into the ark.

All the four-footed beaſts might have been eaſily lodged in ſix and thirty ſtables; and all the birds in as many voleries; allowing for each ſtable and volery, five and twenty feet and an half in length, nine and twenty in width, and thirteen and an half in height.

There might be more than thirty-one thouſand one hundred and ſeventy-four buſhels of freſh water in the keel; which is more than ſufficient for four times as many men and beaſts to drink in one year, as were in the ark.

The granary and magazine, which was in the firſt ſtory, might contain more proviſions than were neceſſary for the nouriſhment of all the animals in the ark for one year; whether they all lived on hay, fruits, and herbs; or whether there were ſheep deſigned for the food of ſuch animals as live on fleſh.

Beſides the places requiſite for the beaſts and birds, and their proviſions, Noah might ſpare room in the third ſtory for ſix and thirty cabbins to depoſit his houſhold utenſils, the inſtruments of huſbandry, grains and ſeeds to ſow the earth with after the deluge. He might make room in it for a kitchen, a hall, four chambers, and a ſpace of about eight and forty cubits in length to walk in. The reader may conſult M. le Pelletier's work upon Noah's ark, and that of John Buteo on the ſame ſubject.

There are ſeveral difficulties propoſed with relation to Noah's ark. For example, one queſtion is, How long time Noah was employed in building it? Interpreters generally believe, that he was an hundred and twenty years; and this opinion is founded upon the following words of Gen. vi. ver. 3. "My Spirit ſhall not always "ſtrive with man; his days ſhall be an hundred and "twenty years." Some have pretended, that God in this deſigned to declare, that there were not above an hundred and twenty years to the deluge, and that this time was neceſſary for Noah to make his preparations, build the ark, preach repentance to mankind, and collect together the proviſions and animals which were to be conveyed into the ark.

But how ſhall we be able to reconcile all this to what is elſewhere ſaid, of Noah's being five hundred years old when he had Shem, Ham, and Japhet? And when God commanded him to build the ark, he ſaid, Thou, and thy ſons, and thy wife, and thy ſons wives with thee. Noah therefore, at that time, had not only his three ſons, who were not born till after the five hundredth year of his age, but his three ſons were all married; and it is certain that the deluge happened in the ſix hundredth year of Noah. It is impoſſible therefore that he ſhould have received orders to build the ark an hundred years before the deluge.

Some of the ancient fathers reply, that the five hundred years of Noah, mentioned in chap. v. ver. 22. of Gen. are ſet down here for five hundred and twenty; a round number for a broken one; and that Noah was really five hundred and twenty years old when God commanded him to build the ark. Others affirm, that of the hundred and twenty years, which God allowed them for repentance, he cut off twenty, that the deluge began at the end of an hundred inſtead of an hundred and twenty years, as had been appointed.

But theſe anſwers are mere conjectures, advanced without any ſolid proof; and therefore far from being ſufficient to deſtroy plain and expreſs texts; beſides, they reſolve but part of the difficulty: for it ſtill remains a queſtion, how Noah, between the age of five hundred, and five hundred and twenty years, could have his three ſons and marry them; ſo as God might ſay to him, "Thou ſhalt come into the ark, thou, and thy ſons, "and thy wife, and thy ſons wives with thee." It is very difficult to believe, that at this time, when men lived eight or nine hundred years, they ſhould be marriageable at ſeventeen or eighteen. Laſtly, it may be ſaid, that when Noah is declared to have begotten Shem, Ham, Japhet, at five hundred years of age, it ſhould be tranſlated, He had begotten, inſtead of, he begat.

There are likewiſe many commentators, who allow Noah only two and fifty years to build the ark; ſome no more than ſeven or eight years; and others ſtill much leſs. The Mahometans ſay he had but two years allowed him for this work.

As to the particular ſort of wood whereof the ark was built, the Hebrew imports, that it was gopher-wood; the Septuagint tranſlate this, ſquare pieces of wood; others ſay it was cedar, or box, or ſome other ſtrong wood. Bochart maintains, that gopher ſignifies cypreſs: and it ſhould be remembered that in Armenia and Aſſyria, where it is ſuppoſed with reaſon, the ark was built, cypreſs is the only wood fit to make a long veſſel, ſuch as the ark was. Alexander the Great, deſigning to build a fleet, could find no wood proper for this uſe in Babylonia, but was forced to have cypreſs brought from Aſſyria. Others are of opinion, that the Hebrew gopher ſignifies, in general, oily and gummy woods, ſuch as the pine, the fir-tree, and the turpentine-tree. The word gophrit, which comes very near gopher, ſignifies ſulphur, and in a larger ſenſe may be taken for roſin, pitch, and other combuſtible matters drawn from wood. St. Jerom tranſlates it in this place, poliſhed wood; but in another he interprets the Hebrew, wood done over with bitumen, ligna bituminata. The paraphraſts Onkelos and Jonathan, and ſome others, have thought this wood to be cedar: and it muſt be owned, that it is a point which ſtill remains undecided; but if our opinion would be of any weight, we ſhould prefer that which ſuppoſes it to mean cypreſs.

But the greateſt difficulty relating to Noah's ark, regards its ſize and capacity; and how they were able to build a veſſel ſufficient to contain the men and beaſts, beſides the proviſions neceſſary for the ſupport of both, during the whole year. To remove theſe difficulties, it has been neceſſary to be very particular in enquiring into the length of the cubit mentioned by Moſes, into the number of the beaſts that were admitted into the ark, as well as into the dimenſions of this vaſt building; and after the niceſt examination, computations, and taking the dimenſions with the utmoſt geometrical accuracy, the moſt learned and able calculators conclude, that if the greateſt mathematicians had been conſulted, with regard to regulating the proportions of the ſeveral apartments in the ark, they could not have done it with more exactneſs than Moſes has done; and the narration in the ſacred hiſtory, in this particular, is ſo far from furniſhing deiſts with weapons to attack its authority, that on the contrary, it ſupplies us with good arguments to confirm it: for it ſeems impoſſible for a man, in the times of Noah, when navigation was in its infancy, to diſcover, by his own wit and invention, ſuch an accuracy and regularity in proportion, as is remarkable in the different apartments of the ark, and the end for which they were deſigned. It therefore follows, that it muſt be owing to a ſuperior light, and the inſpiration of the Deity.

Ark *of the Covenant*, among the Jews, implies a ſmall cheſt made of beaten gold, wherein were contained the golden pot filled with manna, Aaron's rod, and the tables of the covenant.

ARM, *Brachium*, a part of the human body, terminating at one end in the ſhoulder, and at the other in the hand.

Anatomiſts divide the arm into two parts, calling only that part the arm included between the ſhoulder and the elbow; the reſt they term the fore-arm. The arm in this acceptation has only one large bone, called the os humeri, or the ſhoulder bone. The other part conſiſts of two bones, termed the radius, and the cubitus, or ulna.

The os-humeri has five ſorts of motions, which are effected by five pairs of muſcles; upwards by the deltoides, ſupraſpinatus, and coraco-brachialis; downwards by the rotundus major, and latiſſimus dorſi; forwards by the pectoralis; and backwards by the infraſpinatus.

The muſcles of the fore-arm are the biceps, brachiæus internus, gemellus, brachiæus externus, anconæus, pronator, radii teres et quadratus, ſupiſpinator longus et brevis. Its motions are confined to two kinds, that of rotation, and that of flexion and extenſion.

Arm, among ſportſmen, is applied to a horſe, when by preſſing down his head, he endeavours to defend himſelf againſt the bit, to prevent his being checked by it.

Arm, in geography, implies a branch of the ſea, running ſome diſtance into the land.

Arm *of a Magnet* is a ſmall piece of ſteel in the iron incloſure, in which the load-ſtone is placed. See Magnet.

ARMADILLO, in natural hiſtory, the name of an animal reſembling a hedge-hog, and almoſt of the ſame ſize. His head, body, and tail, are covered with a ſhield of a bony ſubſtance, and very curiouſly contrived with moſt beautiful ſcales. Near the hind part of the head are two joints, that he may move his head; and on the back ſeven diviſions, or ſhields, with a yellow ſkin between each. The feet are alſo covered with a thinner ſhield. The lower parts of his body are without this covering, but are beſet with hairs near an inch long, which proceed from prominent pores. There are alſo a few hairs on the ſkin, which joins to ſeveral ſhells of the ſhield, like the former; as alſo near the mouth and eyes.

The head is like a hog, with a ſharp ſnout: it has little eyes ſunk deep in the head, and a pointed narrow tongue. The ears are naked, brown, and ſhort; the teeth are of a middle ſize, and eighteen in each jaw. The feet reſemble hands, with five fingers, and roundiſh nails. He roots up the ground with his ſnout, like a hog; and is tinctured all over with a reddiſh colour. The tail at the root is near four inches thick; but grows leſs gradually to the end, which terminates in a point. He lives upon melons, potatoes, and other roots; and will eat fleſh when he can get it. He generally lies hid in the ground, and ſometimes will frequent water and watery places, where he feeds upon worms, ſmall fiſh, and water inſects. Sometimes he will eat ants, apples, and the berries of certain trees. See plate IV. *fig.* 6.

The armadillo of the Caribbee iſlands, is of the ſize of a pig of a month old, with a ſmall long head, little eyes, and a mouth well furniſhed with teeth, and the ears are likewiſe little; but the tail is long, and covered with bony rings or ſhells. The legs are ſhort and thick, and it has four claws on each foot, which are large and ſtrong. The whole body, from the neck to the tail, is covered with rows of ſhells; and the firſt and the laſt, namely, that which covers the ſhoulders and thighs, are much larger than thoſe on the reſt of the body. There are about twelve ſhells in all, which ſlide over each other like the joints of a coat of armour, by means of a ſkin like a griſtle, which unites them together. They are of a dirty grey colour, with a few little white ſpots.

This animal has a quick feeling, and will roll himſelf up like a ball, when his ſhells are a little preſſed. Beſides the above motion of the ſhells, they are alſo capable of ſtretching conſiderably; or rather, it is the membrane that ties them together, which has that faculty; and this renders the motion of the animal much more quick and eaſy than it otherwiſe would be. The ſkin under the belly is without hair, and ſeems to be very tender and delicate; it is likewiſe of a grey colour.

When he is afraid, he withdraws his head under his ſhell, and lets nothing be ſeen but the end of the ſnout. He then draws up his feet under his belly, and his tail under them; ſo that his ſhell entirely covers them; and the two extremities of this animal meeting together, he becomes as round as a ball, a little flattiſh on each ſide.

Hence it appears he may be very eaſily taken when he is rolled up in this manner; but he is not very willing to unfold himſelf; for the more he is in danger, the more he contracts his covering. The only way to make him open is to lay him near a fire; for as ſoon as he feels the heat he diſplays his limbs. He lives upon leaves, fruit, and roots, which he lays bare with his paws, and cuts with his teeth. He cannot run very faſt, much leſs climb up trees; and his lurking places are the ſtumps and bodies of trees which are hollow. The fleſh is white, fat, and delicate; but it is beſt when ſeaſoned with ſpices to quicken the taſte.

The African Armadillo is called by ſome the cataphractus; it has twelve ſhields and two girdles. It is only ten inches long, from the tip of the ſnout to the root of the tail; but the tail itſelf is ſeven inches long. There are five toes on each foot, armed with ſtrong claws, and the three in the middle of the fore-feet are the largeſt. The ears, which are pretty long, are roundiſh at the end; and between the two large ſhields are twelve narrow bands, joined together by a thick membraneous ſkin, and covered with ſcales in the ſhape of parallelograms. Thoſe that cover the great ſhield have ſometimes four, ſometimes five, and ſometimes ſix ſides; but they are always unequal. The weaſel-headed armadillo, or tatu, is ſo called from the ſhape of his head, which is like that of a weaſel. The body is eleven inches long and ſix broad; and the head three inches and a half, and the forehead two and a half, and very flat. The end of the ſnout is half an inch broad, and the eyes are little. The ears are two inches diſtant from each other, and an inch in length; and the tail is five inches and a half long. The fore-feet are two inches and a half in length, and three quarters of an inch in breadth. All the feet are divided into five toes; of which the three middlemoſt are two inches long, and they are all armed with claws one third of an inch long.

The head, back, ſides, and tail, are covered with a cruſtaceous ſhield; and the helmet and the cover of the feet conſiſt of roundiſh ſcales a quarter of an inch broad. The collar is a plate made up of ſquare bits a quarter of an inch broad, and the cover of the ſhoulder conſiſts of ſquare ſegments of various kinds. The armour on the back, as far as the tail, is compounded of ſeveral moveable plates, eighteen in number, connected together with as many membranes. The plates before are the largeſt, and conſiſt of ſquare ſegments, half an inch in length, and a quarter of one broad; but theſe behind are made up of thoſe that are round and ſquare, mixed together. The fore-part of the tail is compoſed of ſix rings; but the latter is covered with ſcales, and the breaſt, belly, and ears, are naked. *Brookes's Nat. Hiſt.*

ARMENICA, apricot, in botany. See APRICOT.

ARMENIANS, in eccleſiaſtical hiſtory, a ſect, or diviſion, among the eaſtern chriſtians, ſo called from Armenia, the country they originally inhabited: there are two kinds of Armenians, the one catholic, and ſubject to the pope, having a patriarch in Perſia, and another in Poland; the other form a peculiar ſect, and have two patriarchs in Natolia. They are generally accuſed of being Monophyſites, admitting only of one nature in Chriſt. With regard to the euchariſt, they, in general, agree with the Greeks; abſtain religiouſly from eating of blood and things ſtrangled; and are much addicted to faſting.

ARMILLA-MEMBROSA, in anatomy, is that circular ligament which comprehends all the tendons belonging to the whole hand within a circle, in the region of the carpus.

ARMILLARY, in a general ſenſe, implies ſomething compoſed of rings or circles.

The word is Latin, *armillaris*, and derived from *armilla*, a bracelet.

ARMILLARY *Sphere*, an artificial ſphere compoſed of a number of circles of the mundane ſphere, put together in their natural order, to eaſe and aſſiſt the imagination, in conceiving the conſtitution of the heavens, and the motions of the celeſtial bodies. See pl. IV. *fig.* 11.

The armillary ſphere revolves upon its axis within a ſilvered horizon, which is divided into degrees, and moveable every way upon a braſs ſupporter. The other parts are the equinoctial, zodiac, meridian, the two tropics, and the two polar circles.

ARMINIANS, in eccleſiaſtical hiſtory, are a ſect of Chriſtians that aroſe in Holland, by a ſeparation from the Calviniſts.

They are great aſſertors of free-will; and ſpeak very ambiguouſly of the preſcience of God. They look on the doctrine of the Trinity as a point not neceſſary to ſalvation, and many of them hold that there is no precept in Scripture which enjoins us to adore the Holy Ghoſt; and that the Son is not equal to the Father.

ARMISTICE, in military affairs, a temporary truce, or ceſſation of arms for a very ſhort ſpace of time.

The word is Latin, *armiſtitium*, and compounded of *arma*, arms, and *ſto*, to ſtand, or ſtop.

ARMOSIN, a kind of ſilk ſtuff, manufactured in the Eaſt-Indies, at Lyons in France, and at Lucca in Italy.

ARMONIAC, or AMMONIAC. See SAL *Ammoniacum*.

ARMORIAL, ſomething relating to arms, or coats of arms.

ARMORY, a magazine of arms, or a place where military habiliments are depoſited, that they may be ready for uſe.

ARMORY alſo implies a branch of the ſcience of heraldry, conſiſting in the knowledge of coats of arms, with regard to the blazonry and various intendments.

ARMOUR, all ſuch habiliments as ſerve to defend the body from wounds, eſpecially thoſe given by darts, ſwords, lances, &c.

ARMOURER, a perſon who makes or deals in arms or armour.

ARMS, *Arma*, in a general ſenſe, all kinds of weapons, whether offenſive or defenſive.

ARMS, in a legal ſenſe, extend to any thing a perſon wears for his own defence, or takes in his hand, and uſes in anger, to ſtrike or throw at another.

ARMS, or ARMORIES, in heraldry, ſignify marks of honour borne upon ſhields, banners, and coats, in order to diſtinguiſh kingdoms, ſtates, families, and perſons.

Charged ARMS are ſuch as retain their ancient integrity, with the addition of ſome new honourable bearing.

Canting or *Vocal* ARMS, thoſe in which there are ſome figures alluding to the name of the family.

Full or *Intire* ARMS, ſuch as retain their primitive purity, without any alterations or abatements.

Falſe ARMS, ſuch as are not conformable to the rules of heraldry.

ARMS, in falconry, imply the legs of a hawk from the thigh to the foot.

ARMY, a large number of ſoldiers, conſiſting of horſe and foot, completely armed, and provided with artillery, ammunition, &c. under the command of one general, with proper officers under him.

An army is compoſed of ſquadrons and battalions, and is uſually divided into three corps, and formed into three lines. The firſt is called the van-guard, the ſecond the main body, and the third the rear-guard.

ARNOLDISTS, in eccleſiaſtical hiſtory, a ſect of ſeparatiſts, ſo called from their leader, Arnold of Breſſe, a great declaimer againſt the wealth and vices of the clergy. He is alſo charged with preaching againſt baptiſm and the euchariſt.

AROMATIC, an epithet applied to ſuch plants and other bodies as yield a fine fragrant ſmell, and have a warm ſpicy taſte.

AROPH, a term frequently uſed by Paracelſus for lithontriptic medicines.

AROURA, a Grecian long meaſure, containing fifty feet. It was alſo frequently uſed for a ſquare meaſure of half the plethron. The Egyptian aroura was the ſquare of a hundred cubits.

ARPENT, a term ſometimes uſed to denote an acre.

ARQUEBUSS. See HARQUEBUSS.

ARRACHEE, in heraldry, a term applied to the repreſentation of plants torn up by the roots.

ARRAC. See ARAC.

ARRAY, in law, implies the ranking or ſetting forth a jury or inqueſt of men impannelled on ſome cauſe.

Battle ARRAY, the order or diſpoſition of an army drawn up with a view to engage the enemy.

ARREARS, the remainder of a ſum due, or money remaining in the hands of an accountant. It likewiſe ſignifies the money due for rent, wages, &c. or what remains unpaid of penſions, taxes, &c.

ARRENATION, in the foreſt laws, implies the licenſing the owner of lands in a foreſt, to incloſe them with a low hedge and a ſmall ditch, in conſideration of a yearly rent.

ARREST, the apprehending and ſeizing a perſon, in order to oblige him to be obedient to the law; which in all caſes, except treaſon, felony, or breach of the peace, muſt be done by virtue of a precept out of ſome court. See WRIT.

ARREST *of Judgment*, the aſſigning juſt reaſon why judgment ſhould not paſs, as want of notice of the trial; a material defect in the pleading, when the record differs from the deed impleaded, when perſons are miſ-named, where more is given by the verdict than is laid in the declaration, &c. This may be done either in criminal or civil caſes.

ARRESTS, in farriery, mangy tumours between the ham and the paſtern of a horſe's hind legs. See RAT-TAILS.

ARRHEPHORIA, a feſtival among the Athenians, in honour of Minerva. The miniſters who aſſiſted at it were boys and girls, between ſeven and twelve years of age.

The word is Greek, and compounded of αρρητον, myſtery, and φερω, to carry.

This feaſt was alſo called Herſiphori, from Herſe, the daughter of Cecrops, on whoſe account it was inſtituted.

ARRIERE, the hinder or poſterior part of any thing. See REAR.

ARRONDEE, in heraldry, implies a croſs, the arms of which are compoſed of ſections of a circle.

ARROW, a miſſive weapon, ſharp pointed and barbed, deſigned to be ſhot from a bow. See BOW.

ARROW, among ſurveyors, implies a ſmall ſtick generally ſhod with iron, to ſtick into the ground at the end of the chain.

ARSCHIN, in commerce, a long meaſure uſed in China to meaſure ſtuffs. Four arſchins make three Engliſh yards.

ARSENIC, a poiſonous mineral ſubſtance, frequently found mixed with other matters.

The chemiſts have formed various conjectures about the nature of this ſingular concrete; but have not been able to determine what it really is, or to what claſs of bodies it belongs. They have called it ſulphureous, unctuous, mercurial, a mineral juice, &c. without foundation. Boerhaave, in his "Elementa Chemiæ," ranks it under the head of ſulphurs, and ſays it approaches nearer to the nature of ſulphur than of any other known mixt body: it wants, however, the pecular qualities by which ſulphur is diſtinguiſhed. Stahl, with greater probability, ſuppoſes it to be of a ſaline nature. In ſome of its ſtates, it apparently poſſeſſes properties attributed to ſalts alone; but in other ſtates, it is as obviouſly metallic.

White arſenic, or arſenic ſtrictly ſo called, is a moderately heavy, compact, hard, brittle concrete; of a cryſtalline or vitreous appearance, gradually changing, from expoſure to the air, to a milky hue like that of porcelain, and at length to the opake whiteneſs of white enamel. The larger maſſes preſerve their tranſparency longer than the ſmall; in a dry longer than in a moiſt air.

In the fire, it neither burns, nor perfectly melts; but totally and readily exhales in thick fumes, of a ſtrong fetid ſmell reſembling that of garlic. The fumes, caught in proper veſſels, condenſe, either into cryſtalline maſſes again, or into a white powder, according as the receiver is leſs or more removed from the heat.

Mixed with inflammable matters, and expoſed to the fire in a retort or other like veſſel, it aſſumes a metallic appearance. In this ſtate, it greatly reſembles regulus of antimony; being, like that ſemimetal, of a bright ſparkling whitiſh colour, a plated or leafy texture, and very brittle: but its whiteneſs ſoon changes in the air to a dark blackiſh hue. It ſtill continues volatile, as in its unmetallic form: it burns and calcines in the fire, and ſublimes into white arſenic, as at firſt.

Arſenic reduced into fine powder, and boiled in fifteen times its weight of water, totally diſſolves. If the ſolution be evaporated a little, the arſenic ſhoots, on cooling, into cryſtals, which frequently have a yellowiſh tinge. The entire cryſtals are not taken up again by boiling water; but when finely pulverized, they diſſolve as at firſt. The ſolution has a nauſeous taſte, but not a ſaline ſharpneſs.

Arſenic diſſolves both in acid and in alkaline liquors, but makes no efferveſcence with either: in fixed alkaline lixivia it diſſolves very plentifully; in acids, more ſparingly. Arſenic in its ſemimetallic form, called regulus, is eaſier of ſolution than the white arſenic or calx.

Arſenic is employed for ſundry mechanic uſes; by the dyers, as an ingredient in the compoſitions of ſcarlet and other fine reds; by the girdlers and pinmakers, for whitening their braſs or copper; by the goldſmiths, for enamelling; by the glaſs-makers, for promoting the fuſion of the fritt, and the clearneſs and tranſparency of the glaſs; by the porcelane-makers, in white glazings; by the preparers of compound metals, for communicating a ſilver whiteneſs to copper; by the aſſayers, it is uſed in the form of glaſs, for promoting the ſcorification of refractory ores, which participate of tin and antimony, and which will not work off, but run into lumps in the cupel. A certain artiſt at Berlin prepares a beautiful metal, like the fineſt ſteel, by melting caſt iron with arſenic and glaſs, and adding a little tin during the fuſion: the beauty of the metal depends in a great meaſure upon the proportions. In Vienna, a metal is made for ornamental uſes, reſembling the fineſt ſilver, from iron, tin, and arſenic; perhaps with the addition of a little copper. Arſenic is uſed alſo in ſolders, or for uniting iron with tin, in ſome places in the making of tinned iron plates.

Arſenic is a moſt violent poiſon to all animals; unleſs the wolf ſhould be an exception, who is ſaid, probably without ſufficient foundation, to be only purged by it. The utmoſt caution is therefore neceſſary, in all operations upon arſenic, to avoid its fumes: it is on account of the danger attending ſuch operations that this mineral has hitherto been ſo little examined by the chemiſts. The deſtroying of rats, or other domeſtic animals, by means of arſenic, is full of danger; the operation of the poiſon being ſuch, that great part of it is diſcharged, and the animal induced to drink: hence foods, liquors, and the provender of cattle, have too often received a poiſonous taint. If we cannot catch thoſe animals, we may nevertheleſs be cleared from them by much ſafer means than the uſe of arſenic: freſh night-ſhade is their enemy. If the juice of the leaves or berries of that plant, or the diſtilled water of the freſh herb, be made into pellets with meal, the rats, without taſting the pellets, will forſake the places where they are laid.

With regard to the effects of arſenic in the human body; a nauſea, ſickneſs, and reaching commonly enſue in about half an hour after taking it; followed by violent vomitings, hiccups, and pains in the ſtomach and bowels: convulſions and palſies of the limbs preſently ſucceed, with intenſe heats, cold ſweats, palpitations of the heart, extreme anxiety, reſtleſſneſs, proſtration of ſtrength, thirſt and dryneſs of the mouth and throat, loſs of reaſon, and at laſt death. If the quantity taken has been conſiderable, the ſtomach and inteſtines are often found, upon diſſection, corroded or perforated; though in general the patient expires before the action of the poiſon has proceeded to ſuch a length. There are many poiſons which act by coagulating the juices; but the operation of arſenic is erroneouſly ſuppoſed to be of this kind: arſenic rather liquifies than coagulates the blood, and makes no change in its colour: of milk, ſaliva, and other animal juices, it rather prevents than promotes the coagulation. It is better to acknowledge our ignorance than to advance groundleſs conjectures.

Several ſubſtances have been propoſed as antidotes to this poiſon. Thoſe who imagine arſenic to be an alkali, recommend acids; and thoſe who imagine it a corroſive acid, direct alkalies for counteracting its effects: but arſenic is apparently neither one or the other. If rock cryſtal, or bezoar, or the roots of the elder tree, by ſome ſtrongly recommended, have ſeemed to do ſervice where arſenic had been taken; it was not on thoſe ingredients, but on the oils or fats uſed along with them, that the good effects of the medicine depended. Oils, fats, warm fat broths, freſh butter, milk, taken plentifully and repeatedly, are the only antidotes; both for obtunding the force of the arſenic, and promoting its diſcharge by vomit. If the vomiting does not freely ſucceed by the liberal uſe of theſe kinds of ſubſtances, ſome mild emetic muſt be added; the expulſion of the poiſon being a principal point. The more threatening ſymptoms being thus removed, oily clyſters, and a gentle laxative, are neceſſary, to obtund and evacuate ſuch part of the arſenic as may have paſſed into the inteſtines; after which, the ſtrength is to be recruited by proper analeptics.

Caſes frequently happen in which we are called upon to determine whether a particular ſubſtance be arſenic or not; as when powdery matters are found in the ſtomach of thoſe who are ſuſpected to have died by poiſon. Arſenic, in a ſolid form, may be diſtinguiſhed by its yielding, in the fire, white fumes, and a garlic ſmell; and by its whitening copper. This laſt trial is moſt commodiouſly made, by placing a little of the powder betwixt two clean poliſhed copper-plates, binding the plates firmly together with wire, cloſing the juncture all round with a good lute, and then heating them red-hot. We may try alſo whether any reguline or ſemimetallic matter is obtainable, by means of tartar and ſuet.

The principal preparations of arſenic are, fixed arſenic, and the arſenical magnet. Fixed arſenic is made by gradually injecting powdered arſenic into melted nitre, commonly in the proportion of one part of the former to two of the latter. When the ebullition is over, the crucible is covered, the matter kept melted for a little time with a ſtrong fire, and afterwards edulcorated with water. The arſenical magnet is a mixture of equal parts of pure white arſenic, ſulphur, and antimony, reduced ſeparately into fine powder, then mixed, put into a glaſs body ſet in ſand in a crucible, and urged with a very gradual fire, till the matter is melted into a red vitreous maſs reſembling a deep garnet or ruby. We muſt be cautious in handling this arſenical glaſs, as a wound received from it may be dangerous.

Pure cryſtalline white arſenic is never found native in the earth. A powdery white arſenic is now and then met with in ſome of the Bohemian and Saxon mines; though even this ſeems to be not a natural arſenic, but to have been ſeparated and ſublimed from the ores, by the wood fires made in the mines for burſting the maſſes of ore. It is obſervable, that Saxony, of all countries in the world, is the richeſt in arſenical ores; and that the richeſt ſilver-ores abound with arſenic. *Neumann's Chemiſtry.*

ARSIS and THESIS, in muſic, is a term applied to compoſitions, in which one part riſes and the other falls.

ARSMART, in botany, the name of ſeveral ſpecies of perſicaria. See PERSICARIA.

ART, *Ars*, a ſyſtem of rules ſerving to facilitate the performance of certain actions; in which ſenſe it ſtands oppoſed to ſcience, or a ſyſtem of ſpeculative principles.

Arts are commonly divided into liberal and mechanical; the former comprehending poetry, painting, ſculpture, architecture, &c. and the latter, the whole body of mechanical trades, as carpentry, maſonry, turnery, &c.

ART and PART, in the law of Scotland, is applied to an accomplice.

ARTEMESIA, mugwort, in botany, the name of a plant, whoſe ſtalks are firm, and generally of a purpliſh colour: the leaves are deeply divided, reſembling thoſe of common wormwood, of a dark green colour above, and hoary underneath: the flowers, which are ſmall, naked, and diſcous, ſtand erect in ſpikes on the tops of the branches. It is perennial, grows wild in the fields and waſte grounds, and flowers in June.

This plant has been chiefly recommended for promoting the uterine evacuations, and abating hyſteric ſpaſms; for which purpoſe infuſions of it have been drank as tea, and uſed as a bath. It appears to be one of the mildeſt of the ſubſtances made uſe of in ſuch intentions; and may perhaps be of ſervice in ſome caſes, where medicines of more activity would be improper.

ARTERIAL, in anatomy, any thing belonging to, or that performs the office of, an artery.

ARTERIAL *Vein*, in anatomy, a name given to the pulmonary artery.

ARTERIOTOMY, the opening an artery in order to procure an evacuation of blood.

The word is Greek, αρτηριοτομια, and compounded of αρτηρια, an artery, and τεμνω, to cut.

ARTERY, in anatomy, a conical tube or canal, which conveys the blood from the heart to all parts of the body.

An artery is compoſed of three membranes or coats; the outermoſt of which appears to be a web of fine blood veſſels and nerves, for conveying nouriſhment to the interior membranes. The next is compoſed of circular or ſpiral fibres, of which there are more or fewer, according to the magnitude of the artery. Theſe fibres, being very elaſtic, contract themſelves with ſome force, when the power ceaſes by which they have been extended. The third and innermoſt membrane is of a denſe contexture, yet fine and tranſparent. It ſerves to keep the blood within its channels, which otherwiſe would, upon the dilatation of the artery, ſeparate the ſpiral fibres from one another. The pulſe of the arteries conſiſts of two reciprocal motions, like the pulſe of the heart, being a ſyſtole and a diaſtole, keeping oppoſite times; the ſyſtole of the one anſwering to the diaſtole of the other.

The arteries of the human body are, ſtrictly ſpeaking, only two, namely, the aorta, and the pulmonary artery; all the other arteries, tho' diſtinguiſhed by proper names, being only branches of theſe two.

The aſcending aorta, which ariſes immediately from the left ventricle of the heart, preſently after gives two arteries, called coronary ones, to the heart itſelf. A little above this it is divided into three aſcending branches, from which are formed the two carotids, and the two ſubclavians; and from theſe laſt proceed the muſcularis colli, the external ſcapulary artery, the ſuperior intercoſtals, the mediaſtinal artery, the ſuperior diaphragmatic artery, the mammary artery, and the axillary arteries: all which are ſubdivided into leſſer branches.

From the deſcending trunk of the aorta, proceed in the following order; the bronchial artery, the inferior intercoſtals, the arteries of the œſophagus, the interior diaphragmatics, the cœliac, ſuperior meſenteric, the renal or emulgent arteries, the ſacra, and two iliacs. Theſe are the main branches ſent out from the deſcending aorta, each of which is again ſubdivided into many leſſer branches.

But *fig.* 1. plate VI. which is taken from Drake's Anatomy, will give a much better idea of the arteries of the human body, than is poſſible to be conveyed by words.

1. The aorta cut from its origin at the left ventricle of the heart. *Fig.* 3. of the ſame plate, repreſents part of the trunk of the aorta turned inſide out; *a*, *a*, the internal, or nervous coat; *b*, *b*, the muſcular coat; *c*, the external, or vaſcular coat.

A. The three ſemi-lunar valves of the aorta, as they appear when they hinder the blood from coming back into the left ventricle of the heart, in its diaſtole.

2, 2. The trunk of the coronary arteries ariſing from the aorta.

3. Ligamentum arterioſum.

4, 4. The ſubclavian arteries.

5, 5. The two carotid arteries.

6, 6. The two vertebral arteries, which ariſe from the ſubclavicula, and paſs through all the tranſverſe proceſſes of the vertebræ of the neck.

7, 7. The arteries which convey blood to the lower part of the face, tongue, adjacent muſcles and glands.

8, 8. The trunks of the temporal arteries ſpringing from the carotids, and giving branches to the parotid glands.

9, 9. Branches of the temporal arteries, conveying blood to the neighbouring muſcles, the hairy ſcalp, and forehead.

10, 10. The trunks which ſend blood to the foramina narium, particularly to the glands of its mucous membrane.

11, 11. The occipital arteries, whoſe trunks paſs cloſe by the mammiform proceſs.

12, 12. Muſcles which carry blood to the fauces, gargareon, and muſcles of thoſe parts.

B, B. Small portions of the baſis of the ſkull, perforated by the artery of the dura mater, part of which is repreſented as hanging to the arteries.

13, 13. The contortions of the carotid arteries, before they paſs the baſis of the ſkull to the brain.

14, 14. Theſe parts of the carotid arteries, where they paſs by each ſide of the ſella turcica, where ſeveral ſmall branches ariſe from them, and help to compoſe the rete mirabile.

C. The glandula pituitaria, taken out of the ſella turcica, lying between the two contorted trunks of the carotid arteries, marked 14, 14.

D, D. The arteriæ ophthalmicæ, which ſpring from the carotids before they enter the pia mater.

15. The contortions of the vertebral arteries, as they paſs the tranſverſe proceſſes of the firſt vertebræ of the neck, towards the os occipitis.

16. The two trunks of the vertebral arteries that lie on the medulla oblongata.

17. The communicant branches between the carotid and cervical artery.

18, 18. The ramifications of the arteries within the ſkull, the larger trunks of which lie between the lobes of the brain, and its ſulci.

E, E. The arteries of the cerebellum.

19, 19. The arteries of the larynx, thyroid glands, and

and adjacent muſcles and parts ariſing from the ſubclavian arteries.

20, 20. Others ariſing near the former, which convey blood to the muſcles of the neck and ſcapula.

21, 21. The mammariæ, which ariſe from the ſubclavian arteries, and deſcend on the cartilages of the true ribs internally, on each ſide the os pectoris or ſternum. Some branches of theſe paſs through the pectoral as well as intercoſtal muſcles, and give blood to the breaſts, where they meet ſome branches of the intercoſtal arteries.

22, 22. The arteries of the muſcles of the os humeri, and ſome of thoſe of the ſcapula.

23, 23. Thoſe parts of the large trunks of the arteries of the arm, which are liable to be wounded in opening the vena baſilica, or innermoſt of the three veins in the bending of the cubit.

25, 25. A communicant branch of an artery ariſing from the trunk of the artery of the arm, above its flexure at the cubit, which is inoſculated with the arteries below the cubit.

26, 26. The external artery of the cubit, which makes the pulſe near the carpus.

27, 27. Arteries of the hands and fingers.

28, 28. The deſcending trunk of the arteria magna.

29. The bronchial artery, ſpringing from one of the intercoſtal arteries: it ſometimes ariſes immediately from the deſcending trunk of the aorta; and at other times from the ſuperior intercoſtal artery which ſprings from the ſubclavian.

30. A ſmall artery, ſpringing from the fore parts of the aorta deſcendens, and paſſing to the gula.

31, 31. The intercoſtal arteries on each ſide the arteria magna deſcendens.

32. The trunk of the arteria cæliaca, whence ſpring,

33 33. The hepatic arteries, and

34. The arteria cyſtica, or the gall-bladder.

35. Arteria coronaria ventriculi inferior.

36. The pylorica.

37. The epiploica dextra, ſiniſtra, and media, ſpringing from the coronaria.

38. The ramifications of the coronary artery, which embrace the bottom of the ſtomach.

39. Coronaria ventriculi ſuperior.

40, 40. The phrenic arteries, or the two arteries of the diaphragm; that on the left ſide ariſing from the trunk of the arteria magna; the right ſpringing from the cæliaca.

41. The trunk of the ſplenic artery, ariſing from the cæliaca, contorted.

42. Two ſmall arteries going to the upper part of the duodenum and pancreas; the reſt of the arteries of the pancreas ſpring from the ſplenic artery in its paſſage to the ſpleen.

43. The trunk of the arteria meſenterica ſuperior turned towards the right ſide.

44. The branches of the ſuperior meſenteric artery, freed from the ſmall guts. Here the various anaſtomoſes the branches of this artery make in the meſentery, before they arrive at the inteſtines, may be obſerved.

45. The inferior meſenteric artery ariſing from the arteria magna.

46. Remarkable anaſtomoſes of the meſenteric artery with the ſuperior.

47, 47. The branches of the inferior meſenteric artery, as they paſs to the inteſtinum colon.

48. Thoſe of the rectum.

49. The emulgent arteries of the kidneys.

50. The vertebral arteries of the loins.

51, 51. The ſpermatic arteries, which deſcend to the teſtes, and are ſo ſmall as to eſcape being filled with wax.

52. Arteria ſacra.

53. Arteriæ iliaci.

54, 54. Rami iliaci externi.

55, 55. Iliaci interni.

56, 56. The two umbilical arteries cut off; that on the right ſide is drawn as in the fœtus, and the left expreſſed as in an adult.

57, 57. The epigaſtric arteries, which aſcend under the right muſcles of the abdomen, and are inoſculated with the mammariæ.

58, 58. Branches of the external iliac arteries, paſſing between the two oblique muſcles of the abdomen.

59, 59. Branches of the internal iliac arteries, which convey the blood to the extenſores and obturatores muſcles of the thighs.

60, 60. The trunks of the arteries which paſs to the penis.

61, 61. The arteries of the bladder.

62, 62. The internal arteries of the pudendum, which, with thoſe here expreſſed with the penis, make the hypogaſtric arteries in women.

63. The penis extended with wax, and dried.

64. The glans penis.

65. The upper part of the dorſum penis, cut from the body of the penis, and raiſed, to ſhew the corpora cavernoſa penis.

66. Corpora cavernoſa penis, freed from the oſſa pubis, and tied after inflation.

67. The two arteries of the penis, as they appear injected with wax.

68. The capſula and ſeptum of the corpora cavernoſa penis.

69. The crural arteries.

70, 70. The arteries which paſs to the muſcles of the thighs and tibiæ.

71. That part of the crural artery that paſſes the ham.

72. The three large trunks of the arteries of the legs.

73. The arteries of the foot, with their communicating branch, from their ſuperior to their inferior trunk, as well as their communications at the extremity of each toe, like thoſe of the fingers.

Rough Artery, or aſpera arteria. See Aspera Arteria.

ARTHANITA, ſowbread, in botany, a low plant, without any other ſtalk than the ſlender pedicles of the leaves and flowers: the leaves are pretty large, round, of a green colour, above with white ſpecks, and purpliſh underneath: the flowers purpliſh, monopetalous, deeply divided into five ſegments, followed by round ſeed veſſels: the roots large, ſomewhat globular, with ſeveral fibres, blackiſh on the outſide, and white within. It is perennial, a native of the ſouthern parts of Europe, and cultivated in ſome of our gardens.

The freſh roots of arthanita have a nauſeous, acrid, biting taſte, and no remarkable ſmell: by drying, their acrimony is greatly abated; by long keeping, it is almoſt deſtroyed; though after they have loſt ſo much as to make very little impreſſion on the organs of taſte, they ſtill betray, when taken internally, a great degree of irritating power. Dried and powdered, they have been given in doſes of a dram, and found to operate as a ſtrong, inflammatory, yet ſlow cathartic. The juice is ſaid to purge ſtrongly when applied externally to the belly: and the juice or bruiſed root to be of great efficacy for ſoftening and diſcuſſing indolent and ſcrophulous tumours. The flowers are of a different nature, having a moderately ſtrong and very pleaſant ſmell, and little other than a mucilaginous taſte: they have been uſed medicinally, and the uſe of the roots is now, among us, in great meaſure laid aſide. *Lewis's Hiſtory of the Materia Medica.*

ARTHRITIS, in medicine, a diſeaſe, well known by the appellation of the gout. See the article Gout.

The word is Greek, and derived from αρθρον, a joint; becauſe the chief ſeat of that diſtemper is in the joints.

ARTHRODIA, in anatomy, a ſpecies of articulation, wherein the flat head of one bone is received into a ſhallow ſocket in the other. The humerus and ſcapula are joined by this ſpecies of articulation.

The word is Greek, and compounded of αρθρον, a joint, and δεχομαι to receive.

ARTHRODIUM, in natural hiſtory, a genus of imperfect cryſtals, always found in complex maſſes, and forming long ſingle pyramids, with very ſhort and ſlender columns. See Crystal.

ARTICHOKE, *Cynara*, in botany, a well-known plant, cultivated in gardens. It requires a rich, deep, and moiſt ſoil, thoroughly dug ſeveral times over, and mixed with plenty of well rotted dung, to the depth of at leaſt three feet; for the deeper the mould is, the leſs watering they will require in the ſummer, and the larger and better flavoured their fruit will be in autumn. They may be raiſed from ſeeds: but the uſual and moſt expeditious way of propagating them is by ſlips, or ſuckers, taken from the old roots in February or March, or as ſoon as the hard froſts are over. Theſe ſuckers ſhould be taken off with ſome fibres to them; and if they are planted in a well prepared ſoil, like the abovementioned, they will yield the next autumn.

The time for taking off theſe ſuckers is alſo the proper ſeaſon for dreſſing the old ſtocks; which is performed thus: After all the earth has been removed from about the ſtock, down to below the part from which the young ſhoots are produced, two, or at moſt three, of the cleareſt, ſtraighteſt, and moſt promiſing of theſe ſhoots, iſſuing from the under part of the ſtock, are choſen for a crop. Theſe are far preferable to the ſtrong thick ſhoots that generally ſpring up from the crown of the roots, with woody ſtems, which never produce good or regularly ſcaled fruit. The gardener then (having previouſly taken off the ſuckers intended for planting elſewhere, in doing of which care muſt be taken not to injure the plants intended to remain) forces off, with his thumb, all the other buds and young ſhoots, cloſe up to the head of the ſtock; ſeparates the young plants that are left, as far aſunder as he can, without breaking them; draws the earth up to them with a ſpade; preſſes it down cloſe around them with his hands; and then pulls off the tops of the leaves which hang down.

Some, when they give this dreſſing, dig their ground all over, and are well rewarded for their pains by the extraordinary fineneſs of their fruit.

When this is done, and the ground laid level, a crop of ſpinage may be ſowed between the ſtocks; for it will be gathered before the artichokes can cover the ground.

Toward the end of April, or beginning of May, when the plants begin to fruit, all the young ſhoots, produced from their roots or ſtems ſince the dreſſing, muſt be pulled up or cut off, ſo as to leave only the principal head, which will by that means bear a fine large fruit. When the artichokes are fit to gather, their ſtems muſt be cut down cloſe to the ground, in order that the ſtocks may make ſtrong freſh ſhoots before the end of October, which is the uſual ſeaſon for earthing them up, or as the gardeners term it, landing them: though this may be deferred till any time in December, if the weather proves mild.

This earthing of them conſiſts in cutting off all the young ſhoots quite cloſe to the ground, then digging a trench between each row, and covering the ſtocks with the earth thrown up, in ſuch manner, that they may be, as nearly as poſſible, under the middle of the ridge. This will ſecure them from any common froſt, and is infinitely better than the uſual practice of covering them with long dung, which never fails to render their fruit ſmall and very thin bottomed; for nothing is more prejudicial to this plant, than the burying of new dung near its roots, or laying it about them; ſo great is the danger of its making them rot, and of its harbouring vermin, which will deſtroy them. If, indeed, hard froſts are apprehended, a quantity of long dung, peas haulm, tanner's bark, or any other light covering, may be laid over the ridges; becauſe it will there be at ſuch a diſtance as not to injure the roots. This covering ſhould not be laid on till there is no avoiding it; and it ſhould be carefully taken off as ſoon as the weather is mild; for the plants will certainly be injured if it lies too long upon them.

The plants, thus earthed up, will not require any farther care before the end of February, or beginning of March, by which time they will have grown through the ridge of mould; and this, if the weather be proper, is the ſeaſon for dreſſing their roots as before directed.

Though the ſtocks of artichokes will laſt ten, or even fifteen years, in a rich and deep ſoil; yet, as they are great impoveriſhers of the ground, their fruit will dwindle, ſo as to render it moſt adviſeable to renew the whole plantation every fourth or fifth year, or, perhaps, rather every ſecond or third: to this end, the ground being prepared, and proviſion made of a ſufficient number of ſuckers choſen in the manner before directed; that is to ſay, clear, ſound, furniſhed with fibres, and not woody; the gardener ſhould pare off the knotted part which joined to the ſtalk. If it cuts criſp and tender, the ſucker is good; but if it be tough and ſtringy, the ſhoot is not worth planting. Having thus ſingled out thoſe that are fitteſt for his purpoſe, he ſhould cut off their large outſide leaves pretty low, in ſuch manner that the middle, or heart leaves, may riſe above them. After this, if the weather be very dry, or the plants have been long taken from the ſtocks, it will be right to ſet their root ends, at leaſt, in a tub of water, for three or four hours, to refreſh them before they are planted. The beſt method of planting them is in rows as ſtraight as poſſible, and at the diſtance of two feet from each other in the row. If there be more rows than one, as generally is the caſe where a full crop is wanted; theſe ſhould be five feet aſunder, and the plants ſhould be ſet quincunx faſhion. They ſhould be planted about four inches deep, the earth ſhould be cloſed very faſt to their roots, and, if the ſeaſon proves dry, they ſhould be watered twice or thrice a week, till they have taken good root. In a favourable ſeaſon, or on a moiſt ſoil, theſe plants will produce the largeſt and beſt artichokes in Auguſt and September, after all the old ſtocks have ceaſed to bear; ſo that a doubly long continuance of this fruit may be had, by making a new plantation every year.

A thin crop of ſpinage may be ſown upon this ground before the plants are ſet; but none of it muſt be ſuffered to grow very near them.

If any of the artichokes, thus planted in the ſpring, ſhould not produce fruit in the autumn, they may be made to yield it in the winter, or early the next ſpring, by tying up their leaves at the time of earthing up their roots, heaping up mould around till only their tops are ſeen, and then covering thoſe tops with a little ſtraw, or peas haulm, to defend them from froſt.

The kitchen gardeners near London, who endeavour to make the moſt of every inch of their high-rated land, generally plant their rows of artichokes nine or ten feet aſunder; and, beſides ſowing between them radiſhes or ſpinage, they plant two rows of cauliflowers, at the diſtance of two feet and an half from each other in the rows, and of four feet from row to row; ſo that full five feet are allowed for the artichokes. In May, when the crop of radiſhes or ſpinage is taken off, they ſow along the middle of the ſpace between the two rows of cauliflowers, a row of cucumbers, for pickling, at the diſtance of every three feet; and between the cauliflowers and the artichokes they plant, for winter uſe, a row of cabbages or ſavoys, which have room enough to grow after the cauliflowers and artichokes are taken off. Thus the ground is fully cropped during the whole ſeaſon.

If the artichoke ſtocks ſhoot but weakly in the ſpring, as they will do if they have been hurt by froſt or too much wet; the beſt way is to uncover them with a ſpade, to looſen and break the mould around them, or rather to dig the whole ground, if it be not planted with any thing elſe, and then to earth up a little the plants of each ſtock. In three weeks or a month's time after this, the ſlips will be fit to take off.

A moiſt rich ſoil always yields the largeſt and beſt artichokes; but if it be very moiſt, the roots will not live through the winter. Such ground ſhould therefore be allotted for freſh plantations made every ſpring, to ſupply the table in autumn, after the old ſtocks have done bearing: and for early fruit, the plants ſhould be in a drier ſituation. It ſhould alſo be open, and at a diſtance from the dripping of trees; for they would draw the plants up in height, and thereby render their fruit poor and ſmall.

The two ſorts of artichokes, commonly cultivated in this country, are the globe and the French. The former, which has by far the moſt fleſhy leaves, the thickeſt bottom, and the beſt taſte, is deſervedly preferred. It is alſo the largeſt. The ſcales of this ſort are brown, and turn inward. The French artichoke is more conical, its ſcales are narrower, of a greener colour, and frequently turned outward, and it has a diſagreeable perfumed flavour.

The bottoms of artichokes are good for many culinary uſes. The way to preſerve them all the winter is, to ſeparate them from the leaves, parboil them, and hang them up in a dry place, ſtrung on packthread, with a clean piece of paper between every bottom, to prevent their touching one another. They are likewiſe ſaid to be very good pickled.

M. de Chateauvieux has raiſed moſt excellent artichokes in the open field, without dunging the ground at all, or even watering the plants; but ſolely by a judicious execution of the principles of the new huſbandry: ſo great are the benefits which accrue from a thorough ſtirring of the earth! Artichokes which he planted at the end of May, produced in September their firſt fruits, which were, in general, from twelve to fifteen inches in circumference. Their leaves covered entirely beds ſix feet wide, in which they were planted.

This renders it highly probable, that if artichokes were always planted in ſingle rows, and in beds, by which means the ground between them may be the more eaſily and more frequently ſtirred, they would thrive better than in the common way of ſetting them in quincunx, or any other form, in ground laid out in one continued flat. The gardeners about great cities will not be brought into this method, nor indeed can they well afford it, becauſe they would hereby loſe ſome of their crops. Yet even here, though laſting plants will not be proper among the artichokes, many others which ſtand but a ſhort time, ſuch as young ſallading, ſpinage, &c. may be cultivated with propriety. *Mills's Huſbandry.*

Jeruſalem ARTICHOKE, the root of a ſpecies of the ſun-flower of the perennial kind, and propagated in ſome gardens for the uſe of the kitchen. It is a very agreeably taſted root, but watry and windy, and therefore at preſent generally diſregarded.

It is propagated by planting out the ſmall roots, or even pieces of the larger, which have buds to them in the ſpring or autumn. They muſt be allowed a very conſiderable diſtance, for they ſpread immoderately, and multiply very quick.

The autumn following, when their ſtems decay, the roots may be taken up for uſe. It is an unſightly plant, though very tall, and therefore placed in the obſcure corners of a garden. *Miller's Gard. Dict.*

ARTICLE, a ſmall part of a book, writing, account, treaty, or the like.

ARTICLE, in anatomy, implies the juncture of two bones deſigned for motion.

ARTICLE, in arithmetic, denotes any number that can be divided into ten equal parts, as 10, 20, 30, &c.

ARTICLE, in grammar, implies a particle uſed in moſt languages for expreſſing the ſeveral caſes and genders of nouns, where different terminations are wanting to ſupply that office.

The Latins have no article; but the Greeks have their ὁ; the eaſtern nations their emphatical *he*; and moſt of the modern languages have recourſe to articles for fixing and aſcertaining the vague ſignification of common and appellative names.

The Engliſh have only two articles *a*, or *an*, when the ſubſtantive begins with a vowel, and *the*, which being prefixed to ſubſtantives, apply their general ſignification to ſome particular thing. Thus we ſay, *a man*, or *the man*; the former confining the general word *man*, to ſome man or other, and the latter to a particular man.

Hence *a* is called an indefinite, and *the*, a definite article; becauſe the former is applied to nouns, taken in a more general and diffuſed ſignification; whereas the latter confines the word to ſome particular object. Thus, if we ſay, It is a happineſs to be a king, the expreſſion is vague, becauſe the word *king* may be underſtood of any king in general: but if we place *the* before the word *king*, inſtead of *a*, the noun *king* will be confined to the monarch of ſome particular people mentioned before.

Articles therefore are of the utmoſt uſe in a language, as by their aſſiſtance general appellations are rendered particular. We are ſurrounded with ſuch an amazing multiplicity of objects, that it would be impoſſible to give each a proper name, and conſequently general terms became neceſſary. But general terms could never anſwer the intention of conveying our ideas to each other by words or writing, unleſs we had ſome method of confining thoſe general terms to particular objects. This is the office of the article; and this it fully performs.

In this particular the Latin labours under a very great diſadvantage. Thus, when the devil ſaid to our Saviour, *Si tu es filius Dei*, it may be rendered *If thou art* a *Son of God*, or, *If thou art* the *Son of God*; and conſequently the ſenſe is ambiguous.

Grammarians are not agreed with regard to the grammatical appellation proper to be given to the article; ſome will have it to be a pronoun, ſome a noun adjective, and others a diſtinct part of ſpeech; but this is a frivolous diſpute, and has no relation to the uſe of the article.

ARTICLE *of Death*, *articulus mortis*, the laſt pangs, or agony of a dying perſon.

ARTICLE *of Faith*, a point of religious doctrine, allowed and received by ſome church or religious ſect, as having been revealed from heaven.

ARTICLES *of the Clergy*, certain ſtatutes relating to eccleſiaſtical perſons and cauſes, made in the reigns of Edward the ſecond and third.

ARTICLES *of Religion*, the thirty-nine heads of the proteſtant faith, drawn up by the biſhops Cranmer and Ridley, and publiſhed by regal authority in the reign of Edward the ſixth.

ARTICULARIS MORBUS, the diſeaſe of the joints, generally called the gout. See GOUT.

ARTICULATE *Sounds*, ſuch ſounds as expreſs the letters, ſyllables, or words of any alphabet or language; ſuch as are formed by the human voice.

ARTICULATED, ſomething furniſhed with or conſiſting of joints.

ARTICULATION, in anatomy, implies the juncture of two bones intended for motion.

Articulation is of two kinds, diarthroſis and ſynarthroſis; the former being that which admits of a manifeſt motion, and the latter that which allows only of an obſcure motion. See DIARTHROSIS and SYNARTHROSIS.

Diarthroſis is ſubdivided into enarthroſis, arthrodia, and ginglymus. See each under its proper article. And ſynarthroſis is ſubdivided into ſymphyſis, ſyntenoſis, ſutura, harmonia, ſyſſarcoſis, ſycondroſis, and ſynneuroſis. See the articles SYMPHYSIS, &c.

ARTIFICER, a perſon whoſe employment it is to manufacture any kind of commodity, as iron, braſs, wood, wool, linen, &c. ſuch as ſmiths, braziers, carpenters, weavers, ſpinners, &c.

ARTIFICIAL, ſomething made, faſhioned, or produced by art, in contradiſtinction to the productions of nature.

This term is as extenſive as the works of art. Thus we ſay artificial bath, day, earthquake, eye, fire, fountain, globe, rainbow, &c. See BATH, DAY, EARTHQUAKE, &c.

ARTILLERY, ordnance of all ſorts with their various appurtenances; as cannons, mortars, petards, muſquets, carbines, &c. See CANNON, MORTAR, &c.

ARTILLERY-PARK, a place generally in the rear of an army for encamping the artillery.

The artillery is drawn up in lines, of which one is formed by the ordnance: the ammunition waggons make two or three lines, ſixty paces behind the ordnance, and thirty diſtant from one another: the pontoons and tumbrils compoſe the laſt line. The whole is ſurrounded with a rope, which forms the park; the gunners and matroſſes encamp on the flanks; and the bombardeers, pontoon-men, and artificers in the rear.

Train of ARTILLERY, a certain number of pieces of ordnance mounted on carriages, with all their furniture, and every thing neceſſary for marching.

ARTILLERY-COMPANY, a band of infantry, conſiſting of ſix hundred men, forming part of the militia or city guard of London.

ARTIST, a perſon ſkilled in ſome art.

ARTOTYRITES, in eccleſiaſtical hiſtory, a ſect in the primitive church, who uſed bread and cheeſe in celebrating the euchariſt.

The word is formed from the Greek, αρτος, bread, and τυρος, cheeſe.

They were a branch of the Montaniſts, and appeared in the ſecond century. They admitted women into the prieſthood and epiſcopacy; and Epiphanius tells us, that it was a common thing to ſee a body of ſeven girls enter their church, dreſſed in white, and each carrying a torch in her hand, where they wept and bewailed the wretchedneſs of human nature, and the miſeries of this life.

ARVAL BROTHERS, *Arvales fratres*, in antiquity, a college of twelve prieſts, inſtituted by Romulus, who preſided over the ambervalia, or ſacrifices annually offered to Bacchus and Ceres.

The word is Latin, and derived from *arvum*, a field; becauſe they offered ſacrifices for the fertility of the field.

Fulgentius has given us the following account of their original: "The nurſe of Romulus, called Laurentia, "had a cuſtom of offering a ſacrifice annually to the "gods for obtaining a plentiful crop; and in theſe re- "ligious exerciſes ſhe was accompanied with her twelve "children. But one of them happening to die, Ro- "mulus, in complaiſance to his nurſe, aſſiſted himſelf to "complete the original number, and gave them the title "of the twelve arval brothers, which they kept ever "after."

They held their aſſemblies in the temple of Concord, and wore on their heads a crown compoſed of the ears of corn, tied together with a white ribbon. Some add, that they were entruſted with the authority of determining the limits of lands and inheritances.

ARUM, wake-robin, or cuckow-pint, in botany, a low perennial plant, growing wild under hedges and by the ſides of banks. It ſends forth, in March, three or four ſmooth leaves, triangular, or ſhaped like the head of a ſpear: theſe are ſucceeded by a naked ſtalk, bearing a purpliſh piſtil incloſed in a long ſheath, which is followed, in July, by a bunch of red berries: the root is irregularly roundiſh, about an inch thick, browniſh on the outſide, and white within. In ſome plants the leaves are ſpotted with black, in others with white ſpots, and in others not ſpotted at all: the black ſpotted ſort is ſuppoſed to be the moſt efficacious; and hence is expreſsly directed by the London college. All the ſorts are ſaid to be ſtronger, when produced in moiſt ſhady ſoils, than in dry open expoſures.

The freſh roots of arum have an extremely pungent acrimonious taſte; ſlightly chewed, they continue to vellicate and burn the tongue (the part which they principally affect) for many hours, producing at the ſame time a conſiderable thirſt: theſe uneaſy ſenſations are ſomewhat alleviated by milk, butter, or oils. The other parts of the plant are likewiſe acrid, though rather leſs ſo than the roots. No part has any ſmell, except the piſtil, which has a faint fetid one.

This root loſes great part of its acrimony on being dried ſufficiently to become pulverable. Kept for ſome time, it ſeems, on firſt chewing, to be an inſipid farinaceous ſubſtance: it ſtill, however, retains a kind of latent pungency, ſo as when chewed long, in any conſiderable quantity, to produce a ſenſation as of a ſlight excoriation of the tongue. Parkinſon obſerves, that the farinaceous ſtarch-like powder has been uſed in waſhing, and that it has bliſtered the hands.

The freſh root, dug up in autumn, yields upon expreſſion about one ſixth of its weight of a milky juice; which, on ſtanding, depoſited a white fecula, and became clear: the clear liquor was inſipid: the fecula was conſiderably pungent; but, like the root in ſubſtance, loſes its pungency on being dried. The freſh and the moderately dried roots were digeſted in water, in wine, in proof ſpirit, and in rectified ſpirit, with and without heat: the liquors received no colour, and little or no taſte. In diſtillation, neither ſpirit nor water brought over any ſenſible impregnation from the arum: the watery and ſpirituous extracts alſo were nearly inſipid. The root, nevertheleſs, loſes in theſe operations almoſt the whole of its pungency.

Arum root, newly dried and powdered, is given in doſes of a ſcruple and upwards; for ſtimulating the ſolids, attenuating viſcid juices, and promoting the natural ſecretions; in cold, languid, phlegmatic habits; againſt weakneſs and relaxations of the ſtomach, and catarrhous and rheumatic diſorders. It has been generally given in conjunction with other materials, to ſome of which the effects of the compound may be in great part aſcribed: thus in the officinal powders of arum, ſixteen grains of the dry root are accompanied with eight grains of the pungent roots of pimpinella, the ſame quantity of thoſe of the yellow water flag, (or of calamus aromaticus) four grains of cinnamon, (or ſix of canella alba) and two grains of ſalt of wormwood, (or of vitriolated tartar) with four grains of crabs-eyes. In the medicine, recommended by Sydenham againſt rheumatiſms, the acrid antiſcorbutic herbs are largely joined to it.

By beating the freſh root with gummy reſins, and making the mixture into pills, its virtue might be better preſerved than in the form of powder: the proportions of the gums, in theſe compoſitions, may be very conſiderable; two or three grains of the arum, in its vigorous ſtate, being a ſufficient doſe. Beaten with ſugar into a conſerve, it likewiſe preſerves it acrimony unabated for ſeveral months; its virtue ſeeming to be retained as long as its native aqueous humidity. The vinous and ſpirituous tinctures, by ſome recommended, appear, from the experiments above related, to be inſignificant; but though ſpirituous liquors are incapable of diſſolving or extracting the active matter of the arum, they ſeem nevertheleſs, when given along with the dried root as a vehicle, to promote its action. Juncker obſerves, that a dram of the powder, taken with a ſpoonful of brandy, procures a very copious ſweat, even in perſons little diſpoſed to that evacuation; while the powder, by itſelf, has no ſuch effect. *Lewis's Hiſtory of the Materia Medica.*

ARUNDELIAN *Marbles*. See MARBLE.

ARUSPICES, in antiquity, an order of prieſts among the Romans, that pretended to foretel future events, by inſpecting the intrails of beaſts killed in ſacrifices.

The word is Latin, and derived from *aſpicio*, to view.

The aruſpices were conſulted on occaſion of all portents and prodigies. Women were admitted into this order.

ARYTÆNOIDES, in anatomy, the name of the third and fourth cartilages of the larynx. See LARYNX.

The word is formed from the Greek, αϱυταινα, an ewer, and ειδος, reſemblance, they being thought to reſemble an ewer in ſhape.

ARYTÆNOIDEUS, in anatomy, one of the muſcles that cloſes the larynx, having its head inſerted in one arytænoid cartilage, and its tail in the other; ſerving at once to draw them together, and ſhut the rima, or glottis.

ARYTHMUS, among phyſicians, implies the want of a juſt modulation in the pulſe; and is oppoſed to eurythmus, or a pulſe modulated according to nature.

The word is Greek, αϱυθμος, and compounded of α, priv. and ρυθμος, meaſure.

AS, in antiquity, a particular weight, among the Romans, conſiſting of twelve ounces, and was the ſame with what they called libra, or a pound.

As was alſo the name of a Roman coin, which was of different weights and different matter in different ages of the commonwealth.

Euſebius tells us, that, under Numa Pompilius, the Roman money was either of wood, leather, or ſhells. In the time of Tullus Hoſtilius it was of braſs, and called *as*, *libra*, *libella*, or *pondo*; becauſe actually weighing a pound, or twelve ounces.

Four hundred and twenty years after, the firſt Punic war having exhauſted the treaſury, they reduced the *as* to two ounces. In the ſecond Punic war, Hannibal preſſing very hard upon them, the reduced the *as* to half its weight, viz. to one ounce. And laſtly, by the Papirian law, they took away half an ounce more, and conſequently reduced the *as* to the diminutive weight of half an ounce: and it is generally thought that it continued the ſame during the commonwealth, and even till the reign of Veſpaſian. The *as* therefore was of four different weights in the commonwealth. Its original ſtamp was that of a ſheep, ox, or ſow. But from the time of the emperors, it had on one ſide a Janus with two faces, and on the reverſe, the roſtrum or prow of a ſhip.

As was alſo uſed to denote any integer or whole; and hence the Engliſh word *ace*.

ASA, or ASSA, in the materia medica, an epithet applied to two very different ſubſtances, called aſa-dulcis, and aſa-fœtida.

Asa-dulcis is the ſame with benzoin. See the article Benzoin.

Asa-foetida is a kind of gum, of a very offenſive ſmell, produced by a plant common in ſome parts of Perſia.

The plant which produces it is one of the pentandria digynia of Linnæus, and one of the herbæ umbelliferæ ſemine foliaceo, ſeu ala foliacea cincto of Ray. We had a multitude of various and falſe accounts of it for a long time; Garcias telling us it had leaves like the hazel; and Bontius making two plants of it, one like a willow, and the other with a root like a turnip; ſome have given it leaves like the fig-tree, ſome like thoſe of rice; and others have made it a ſhrub of the phylleræa kind. Kæmpfer is the author to whom we owe the true account of it. This is given in his Amœnitates Exoticæ, where he deſcribes it fully and accurately, under the name of "umbellifera leviſtico affinis foliis inſtar pæoniæ ramoſis, caule pleno maximo, ſemine foliaceo nudo ſolitario brancæ urſinæ ſive paſtinachæ ſimili radice aſam fætidam fundente." The Perſians call both the plant and the juice hingeſch; and the Indians, hiing; but the more accurate in both countries call the plant hingeſch, and the juice or gum hiing.

The root of this plant is perennial, and very large. It is covered with a thick black rhind, which eaſily comes off from the reſt, when freſh. Within it is perfectly white, and full of white, milky, and ſtinking juice, which, when collected and dried, is what the Perſians call hiing, and the Europeans aſa-fœtida. The top of this root is furniſhed with a large tuft of hairy or filamentous matter, like that on the crown of the meum or ſpignel. The leaves are very large, and like thoſe of the piony.

The ſtalk is as thick as a man's arm, and grows to eight or nine feet high. It gradually becomes taper toward the top, whence it is divided into a ſmall number of branches. The leaves ſtand alternately on theſe ſtalks, and that at no great diſtances from one another. The flowers are ſmall, and diſpoſed in umbels. The ſeeds are flattiſh and ſtriated, and of an oval figure; they have ſomewhat of the aſa-fœtida ſmell, but much leſs than might be expected. It grows in Perſia, but there only in two places, at leaſt in thoſe only in any great plenty. Theſe are the mountains about Heraat, and the province of Laar. In theſe places it abounds with juice, and yields the gum in great plenty; when found elſewhere, it yields very little. The leaves in theſe places are of a horrible, offenſive ſmell, and no animal will touch them: but the people of the town of Diſguum affirm, that, in the country beyond them, the plant loſes much of its bad ſmell, and that the goats feed very greedily on the leaves, and grow fat upon the diet. Some have pretended to diſtinguiſh two ſpecies of this plant, the one yielding a ſmaller quantity of juice, and that of a leſs fetid ſmell; the other yielding more of it, and that more ſtinking: but Kæmpfer, who was upon the ſpot, declares the plants to be the ſame, and all the difference to be in the ſoil that produces them. If what the Perſians of Diſguum ſay be true, however, it very well accounts for the difference of the Cyrenaic and Perſian kinds of ſilphium; for the plant, in the firſt of theſe places, might be as mild as beyond Diſguum, or even more ſo.

It is very ſingular in this plant, that it ſeldom flowers, ſometimes not till its twentieth, thirtieth, or even fortieth year; during all this time the root is increaſing in ſize, and, conſequently, it ſometimes grows to an enormous bulk: roots of it have been ſeen of the thickneſs of a man's thigh, and of a yard and a half in length; thoſe of the thickneſs of one's arm are frequent. When it ſends forth a ſtalk, and has ripened its ſeed, it periſhes. The ancients made a diſtinction in their ſilphium, as it was produced from the ſtalk, or from the root of the plant; but, at this time, all that we have is obtained from the root. They never make inciſions in roots of leſs than four or five years ſtanding; and they always find, that, the older and larger the root, the more plentifully the juice flows.

The gum or juice, as it flows from the root, is white, and perfectly reſembles cream, and has no viſcidity: on the contact of the air it dries or hardens, and becomes viſcous and coloured. The moſt ſtrongly ſcented aſa-fœtida is always eſteemed the beſt; and Kæmpfer obſerves, that it is ſo much ſtronger, when freſh, than when kept and imported into Europe, that a dram of it has more ſcent than an hundred weight of what our druggiſts keep.

The leaves of the plant appear in autumn, and continue green the whole winter; in ſpring they wither. About the end of April, when their leaves are in their decaying ſtate, the Perſians aſcend the mountains in ſearch of the plants. They clear away the earth about the root for ſix or ſeven inches deep; they then twiſt off the leaves, and the fibrous ſubſtance at the top of the root. They next earth up the root again to its top, which is now perfectly bare; and this they cover with a bundle of weeds, to keep off the heat of the ſun, which would otherwiſe deſtroy it. They lay a ſtone over all this, to keep it firm, that the wind may not blow it off; and in this condition they leave the roots for a month or ſix weeks. At the end of this time, they take off the covering, clear away the earth a little from the crown of the root, and, with a ſharp knife, cut it tranſverſly off, taking off about an inch, or a little more, of the top. They then cover this wounded root with the weeds again, making them ſtand hollow from the wounded part, and thus leave them for two days; at the end of which time they return, and find the top of the root, where they had cut it off, covered with exſudated juice, or aſa-fœtida: this they collect, and put up in proper veſſels; and, clearing away the earth a little lower, they cut off another ſlice from the top of the root, but this not thicker than a crown-piece, and cover it up again for another gathering. As they take a large compaſs of ground for their ſearch, they are kept in conſtant employment; the roots of their firſt day's cutting being ready for their taking the gum from, by that time they have cut the more diſtant ones, which they are regularly to return to afterwards. After they have gone through this ſecond operation with all the roots, and collected the ſecond quantity of gum from them, they cover them up for eight or ten days; and, after having ſpread their gum in the ſun to harden it, they carry it home. Four or five men generally go out in a company, on theſe expeditions; and it is a common thing for them to bring home 50 lb. weight of it from this firſt gathering; this, however, is eſteemed but an inferior kind of aſa-fœtida; after the roots have remained covered for eight or ten days, they viſit them again, take off the covering of the weeds, and collect the gum. They then cut off another ſlice of the root, and after that another, and then a third; this is done at the diſtance of two days between each operation, and the earth is every time cleared away to a proper depth, and the whole proceſs managed as before.

After the third collection in this ſecond expedition, they cover up the roots again, and return home with their ſtores, leaving them covered for three days. After this, they return to their work, and cut them again three ſeveral times at the ſame diſtances of time; and, after the third collection of this laſt expedition, they leave them to periſh; for they never recover this terrible operation. *Kæmp. Amœn. Exot.*

Aſa-fœtida is compoſed of a gummy and reſinous ſubſtance, the firſt in the largeſt quantity. Its ſmell and taſte reſide in the reſin; which is readily diſſolved and extracted by pure ſpirit, and the greater part with the gummy matter by water. It is by much the ſtrongeſt of the deobſtruent warm fetid gums; and is given not only againſt hyſterical complaints, flatulent cholics, and obſtructions of the breaſt, but in moſt nervous diſorders, in which it frequently acts as an antiſpaſmodic, and an anodyne: in ſome caſes muſk, and in others opium, are uſefully joined with it. Hoffman recommends it as one of the moſt powerful anthelmintics hitherto known. It is moſt commodiouſly taken in the form of pills, from a few grains to a ſcruple or half a dram. It loſes both its ſmell and ſtrength with age; a circumſtance neceſſary to be attended to in proportioning the doſes neceſſary to be given in order to procure the intended effect.

ASAPPES, or **Azapes**, an order of ſoldiers in the

Turkiſh army, whom they always expoſe to the firſt ſhock of the enemy.

The word is derived from *ſaph*, a word in the Turkiſh language ſignifying rank, file, or order.

ASARUM, aſarabacca, in botany, a low plant without ſtalks: the leaves are ſtiff, roundiſh, with two little ears at the bottom, ſomewhat reſembling a kidney, of a dark ſhining green colour, ſomewhat hairy, ſet on pedicles three or four inches long: the flowers, which riſe among the leaves on ſhorter pedicles, conſiſt of purpliſh ſtamina, ſtanding in a darker-coloured cup, and are each followed by a capſule, containing ſix ſeeds. It is perennial and ever-green, a native of the ſouthern parts of Europe and the warmer climates, and raiſed here in gardens. The dried roots have been generally brought from the Levant; thoſe of our own growth being ſuppoſed of weaker virtue.

The roots and leaves of aſarum have a moderately ſtrong, not very unpleaſant ſmell, ſomething reſembling that of valerian or nard; and a nauſeous bitteriſh acrid taſte. The roots given in ſubſtance, in doſes of a ſcruple or more, prove ſtrongly emetic and cathartic. The leaves have the ſame effect, but their doſe or degree of ſtrength has not been preciſely determined; ſome ſay they are of more activity than the roots.

Its principal uſe among us is as an errhine. The root is one of the ſtrongeſt of the vegetable ſubſtances commonly employed in this intention: a grain or two ſnuffed up the noſe, procure a large evacuation of mucus, both from the mouth and noſtrils, without provoking ſneezing, like the white hellebore root, or diſcovering any remarkable irritation. Geoffroy relates, that after ſnuffing up a doſe of this errhine, he has obſerved the ſalutary diſcharge to continue for three days ſucceſſively, and that he has known a paralyſis of the mouth and tongue cured by one doſe. He recommends this medicine in ſtubborn diſorders of the head proceeding from viſcid matters, in palſies, and in ſoporific diſtempers. During its operation the patient muſt carefully avoid the cold, which is apt to produce puſtules, inflammations, and ſwellings of the face, and ſometimes more alarming ſymptoms. This herb is the principal ingredient in the cephalic, or ſternutatory powders of the ſhops: ſome take equal parts of dried aſarum, and marjoram leaves; others equal parts of the dried leaves of aſarum, marjoram, and marum ſyriacum, and dried lavender flowers. The empyrical herb ſnuffs have likewiſe the leaves of aſarum for their baſis; but often mixed with ingredients of a more dangerous nature.

ASBESTINE, ſome incombuſtible body, or that partakes of the nature and properties of aſbeſtos.

ASBESTOS, ſalamanders wool, in natural hiſtory, the ſame with amianthus. See the article Amianthus.

The word is Greek, and compounded of *α*, priv. and *σβεννυμαι*, to extinguiſh.

ASCARIDES, in medicine, a ſpecies of worms, very ſlender, found in the inteſtinum rectum, chiefly of children, and frequently voided with the fœces. They often adhere to the fundament, and are ſometimes even pendent from it.

The word is Greek, and derived from *ασκαριζω*, to leap; becauſe of their continual motion, which cauſes an intolerable itching.

ASCENDANT, or Ascending *Line*, in genealogy, is underſtood of anceſtors, or ſuch relations as are nearer the root of the family.

Ascendant, in aſtrology, implies the horoſcope, or that degree of the equator which is riſing above the horizon in the eaſt, at the time of the birth of any perſon.

ASCENDENS *Obliquus*, in anatomy. See Obliquus.

ASCENDING, in aſtronomy, is applied to ſuch celeſtial objects as are riſing above the horizon, in any parallel of the equator.

Ascending *Latitude of a Planet* is the latitude of a planet moving towards the north-pole.

Ascending *Node*, that point of a planet's orbit where it paſſes the ecliptic, in its motion towards the north. See Node.

Ascending *Signs*, among aſtrologers, are thoſe riſing from the nadir towards the zenith.

Ascending *Veſſels*, in anatomy, thoſe which carry the blood upwards, as the aorta aſcendens, and vena cava aſcendens.

ASCENSION, in a general ſenſe, implies a moving upwards.

Ascension, in aſtronomy, is either right or oblique.

Right Ascension of the ſun, or of a ſtar, is an arch of the equinoctial intercepted between the vernal equinoctial point, and the meridan that the ſun or ſtar appears in.

The reaſon of thus referring it to the meridian, is, becauſe that is always at right angles to the equinoctial; whereas the horizon is only ſo in a right or direct ſphere.

The right aſcenſion ſtands oppoſed to the right deſcenſion. Two fixed ſtars, which have the ſame right aſcenſion, i. e. are in the ſame meridian, riſe at the ſame time in a right ſphere. If they be not in the ſame meridian, the difference between the time when they riſe is the preciſe difference of their right aſcenſion. In an oblique ſphere, where the horizon cuts all the meridians obliquely, different points of the meridian never riſe or ſet together; ſo that two ſtars on the ſame meridian never riſe or ſet at the ſame time, and the more oblique this ſphere is, the greater is the interval of time between them.

To find the right aſcenſion of the ſun, ſtars, &c. trigonometrically, ſay, As radius is to the coſine of the ſun's greateſt declination, ſo is the tangent of the ſun's longitude from Aries, or Libra, to the tangent of right aſcenſion.—To find the right aſcenſions mechanically by the globe, ſee Globe.

Oblique Ascension is an arch of the equinoctical intercepted between the vernal equinoctial point, and that point of the equinoctial which riſes with the ſun or ſtar.

In order to find the oblique aſcenſion, we muſt firſt find the aſcenſional difference.

ASCENSIONAL *Difference* is the difference between the right and oblique aſcenſion of the ſame point on the ſurface of the ſphere, or it is an arch of the equator intercepted between the points of right and oblique aſcenſion.

To find the aſcenſional difference of the ſun, ſtars, &c. trigonometrically, ſay, As the tangent of the complement of the latitude is to radius, ſo is the tangent of the declination to the ſine of the aſcenſional difference, which being found muſt be added to the right aſcenſion, if the declination and latitude be of different denominations; that is, one north and the other ſouth: but if of the ſame denomination, that is, both north or both ſouth, ſubtracted from the right aſcenſion, ſo will the ſum or remainder be the oblique aſcenſion required.

The aſcenſional difference is always equal to the exceſs or defect of the ſemi-ſolar day, above or under ſix hours; and, conſequently, if (according as the caſe requires) it be reduced into time, by allowing 15°. for one hour, &c. and added to, or ſubtracted from, ſix hours, we ſhall have the length of the day and night, and thence the true time of the ſun's riſing and ſetting. And becauſe, when the ſun is in the equinoctial, or that point where the ecliptic, equinoctial, horizon, and prime vertical, interſect each other, as ♈, he riſes and ſets exactly at ſix o'clock; hence, if the ſun riſes before he arrives at the prime vertical, or ſix o'clock hour circle, he will riſe before ſix of the clock; and, conſequently, we muſt add the aſcenſional difference to ſix hours, to obtain the length of the ſemi-ſolar day; or to twelve hours, to obtain the length of the ſolar day, which will always happen in north latitude, when the ſun hath north declination, and in ſouth latitude, when he has ſouth declination: but if he does not riſe till he has paſſed the prime vertical, we muſt ſubtract the aſcenſional difference from ſix hours, to find the length of the ſemi-ſolar day, which will always happen in north latitude, when he has ſouth declination, and in ſouth latitude, when he has north declination.

To find the oblique aſcenſion, and aſcenſional difference, mechanically, by the globe, ſee Globe.

ASCENT, in a general ſenſe, implies the motion of a body upwards.

Ascent *of Fluids*. See the articles Fluid and Attraction.

Ascent *of Vapours*.—Why vapours are raiſed by heat is no inconſiderable queſtion. And among other things, we do not improperly ſuppoſe in theſe vapours inſenſible bubbles, conſiſting of a pellicle of water and included air. Such a bubble, therefore, being given, but which may contain air rarer than the circumambient, it is poſſible that the rarity of the included air may have greater force than the weight of the including pellicle of water: and therefore, that the entire bubble may be lighter than circumambient air of equal bulk, whereby the bubble, by the laws of hydroſtatics, will aſcend in the ſame manner as a cloſe veſſel of iron full of air would in water, if in proportion to its weight it have a ſufficient capacity; nor is the elaſtic force of the ambient air of greater force in this caſe than the gravity of a column of air; becauſe the elaſtic force in each part ariſes from the gravity of the column. But here will ariſe a great difficulty, namely, that the circumambient air leſs rare than the included air ſeems, by its elaſtic force, as if it would compreſs the bubble; and thus the included air will become of a denſity equal to that of the circumambient air. We are here, therefore, to obſerve, that there is a two-fold force in air, whereby it dilates itſelf, or preſerves its dilatation; the one innate, the other adventitious. The former is the elaſtic force, which exerts itſelf, not only when it is compreſſed into a leſs compaſs than uſual, as in wind guns, but likewiſe in common air, which, as is evident from the experiments of the air-pump, when preſſed by the incumbent air, does, upon removing that preſſure, expand itſelf, if no other air be equally compreſſed, or any other impediment hinder; for flaccid bladders are ſpontaneouſly inflated under the receiver, nay even in the free air, if they are carried from a valley to a high hill; becauſe there they are leſs compreſſed.

The adventitious expanſive force of the air, which ſupplies the place of its elaſticity, is either heat or ſomething elſe analogous to heat in fermentation, or the like natural operation. Thus, it is poſſible that the air included in the bubble, and rarer than the circumambient air, may yet maintain itſelf, and ſuffer a compreſſion from it, which is manifeſt by the experiment of thermometers: and the greater the heat is, or any other force that internally dilates the air, the more will the aqueous pellicle be extended, and become the thinner. But here a new queſtion ariſes, namely, how ſuch bubbles can be formed, ſeeing the heat both of the included and circumambient air ſeems to be the ſame; in anſwer to this, it is to be obſerved, that the included air ſhall acquire a greater degree of heat than that which even the particles of the external air have; becauſe the circumambient air has both a greater and a different motion from the bubble: whence new hot particles thereof continually flowing to the ſame bubble like a hot wind, communicate a new degree of heat to the pellicle, and through it to the included air by the continued contact of new air, as we feel that the hand grows either warmer or colder, if moved in hot or cold water, than if it was at reſt therein: and it is the ſame thing, if the water be moved about the hand, becauſe many aqueous particles ſucceſſively touch the ſame part of the hand, and communicate their quality thereto. From this principle, it appears, that wine, in a glaſs bottle ſwiftly moved up and down in cold water, or the water moved about the bottle, is the ſooner cooled.

Now, if we underſtand the cauſe why the bubbles of vapours aſcend, it will be no difficult matter to explain why they fall down again: for upon the heat gradually vaniſhing, the bubble will be compreſſed by the circumambient air; ſo that the included air, upon the ceaſing of the adventitious dilatation, ſhall return to a like denſity therewith; upon which the aqueous pellicle can neither aſcend in the air, nor ſupport itſelf therein, no more than an iron veſſel can float, or aſcend in water, if it is filled therewith. However, it is poſſible, and it uſually is ſo, that the vapours that are even ready to fall down, remain a little ſuſpended in the air, in the ſame manner in which duſt is ſuſtained therein; becauſe air, as all other fluids, has a certain degree of tenacity or coheſion of its parts, ſo as to require ſome degree of force, however ſmall, to break through it; and becauſe very ſmall bodies have a ſmall weight in proportion to their ſurface; yet, notwithſtanding their weight, they often remain ſuſpended, and they are only toſſed up and down by the motion of the ſuſtaining air. The ſame thing, therefore, happens to bubbles and very ſmall drops; but if a great number of drops concur, which is done by that very toſſing and motion, they coaleſce into a larger one, and becauſe the ſurfaces increaſe only as the ſquares, but the weights as the cubes of their diameters. Hence it is, that a bubble, or drop, by growing larger, acquires a ſufficient force to fall down; and even the ſuperior bubbles, falling on the inferior ones, coaleſce with them, and become bigger.

From theſe principles we ſhall now proceed to ſhew, by a calculus, how great the tenacity of aqueous particles in vapours muſt neceſſarily be, in proportion to the rarity of the included air, that ſuch vapours may aſcend.

Let 1 to d be the ratio of the denſity of the air included in a bubble to the ſpecific gravity of water, and p the weight of common air of the ſame bulk with a bubble of the vapour; let the center of the bubble be A, and A B the radius of the ſphere of included air, but A C the radius of the ſphere of the whole bubble, the ſpace of included air will be as the cube of A B, the ſpace of the whole bubble as the cube of A C, and the ſpace which the pellicle occupies as the difference of theſe cubes. Let us ſuppoſe that ſpace of the pellicle to be to the ſpace of the whole bubble, as 1 to r, the ſpace of the pellicle will be as the cube of $\frac{AC}{r}$, which is equal to the cube of A C — the cube of A B: therefore, the cube of A B is equal to the cube of A C — the cube of $\frac{AC}{r}$ equal the cube of A C $\times 1 - \frac{1}{r}$ equal the cube of A C $\times \frac{r-1}{r}$: and therefore the cube of A B is to the cube of A C, as $r-1$ to r. But the weight of the included air is to that of common air of equal bulk with the bubble, or to p in the compound ratio of the volumes, (or of the cube of A B to the cube of A C, or $r-1$ to r) and of the ſpecific gravities (1 to d) that is, in the ratio of $r-1$ to rd. The weight, therefore, of the included air will be $p \times \frac{r-1}{rd}$: the weight of the including pellicle of water will be in like manner to the weight of common air of equal bulk with the bubble in the compound ratio of the volumes, (1 to r by the hypotheſis) and of the ſpecific gravities 800 to 1; (water being 800 times the ſpecific gravity of air, by experiments) the weight of the pellicle, therefore, will be $\frac{800p}{r}$; but, adding the weight of the pellicle to the weight of the included air, we ſhall have the weight of the whole bubble, which will be $\frac{p\times\overline{r-1+800d}}{rd}$, and that ſhould be leſs than p, the weight of common air of equal bulk with the bubble, that the bubble may aſcend therein; and $r - 1 + 800d$, will be leſs than rd: and, therefore, rdr will be greater than $800d - 1$; and, therefore, r will be greater than $\frac{800d-1}{d-1}$, or the ratio of the ſpace of the bubble to that of the pellicle, will be greater than $800d-1$ to $d-1$. Whence if d be 10, or if common air be 10 times denſer than the included air, the ratio of the ſpace of the bubble to that which the pellicle occupies, will be greater than the ratio of 7999 to 9, or greater than 888.777, &c. to unity; where 888 are unities, but 777, &c. is a decimal fraction; to wit, ,7,07,007, &c. as you would incline to be more exact: and, therefore, the ſpace of the whole bubble will, in this caſe, exceed that of the aqueous pellicle upwards of 888 times. The ratio of the thickneſs of the pellicle to the radius of the ſpherical bubble; that is, the ratio of A C — A B to A C may, from hence, be eaſily determined; for A B is to A C as $\left.\overline{\frac{r-1}{r}}\right|^{\frac{1}{3}}$ to $r^{\frac{1}{3}}$. The thickneſs, therefore, of the pellicle is to the radius of the bubble as $1 - \left.\overline{\frac{r-1}{r}}\right|^{\frac{1}{3}}$ to unity: beſides $r - 1$ is to r as $\frac{r-1}{r}$ to unity; and ſince r is greater than $\frac{800\,d-1}{d-1}$, $\frac{1}{r}$ will be leſs than $\frac{d-1}{800\,d-1}$, and $\frac{r-1}{r}$ will be greater than $1-\frac{d-1}{800\,d-1}$, or than $\frac{800\,d-1-d+1}{800\,d-1}$, or than $\frac{799\,d}{800\,d-1}$: therefore $\overline{\frac{r-1}{r}\Big)}^{\frac{1}{3}}$ is greater than $\overline{\frac{799\,d}{800\,d-1}\Big)}^{\frac{1}{3}}$; therefore at length $1-\overline{\frac{r-1}{r}\Big)}^{\frac{1}{3}}$, or the thickneſs of the pellicle, if unity expreſs the radius of the bubble, is leſs than $1-\overline{\frac{799\,d}{800\,d-1}\Big)}^{\frac{1}{3}}$, that the bubble may aſcend in air.

By the rules which Archimedes has given, it appears that if a veſſel contain a weight of water greater than its own weight, it will float therein; but if ſtill greater veſſels be taken, the weights of the veſſels increaſe nearly as the ſurfaces; but their capacities as the ſolidities, that is, the weights of the veſſels are as the ſquares of the diameters, the capacities (and conſequently the weight of water they contain) as the cubes; and thus, by augmenting the capacity of the veſſel, the weight of the veſſel is immediately overcome by the weight of what it can contain, and the veſſel may float.

From this principle Franciſcus Lana, an ingenious Jeſuit, in an Italian treatiſe, entitled *Prodromo della arte Maeſtra*, had conceived hopes, that a braſs globe might be made of ſuch a capacity, that, when exhauſted of air, it might aſcend and float therein; and for this purpoſe he was of opinion that 16 feet in diameter was ſufficient: but by calculation it may be ſhewn that a globe for that purpoſe muſt be of an immenſe bulk, and which cannot be eaſily prepared by human ſkill; in order to which, let the ſpecific gravity of the metal be to that of air, as m to 1; and as inſtead of a pellicle of water, we uſe a hollow metalline ſphere, therefore, for 800 in the foregoing proceſs, there will be m, and, inſtead of $\frac{800\,d-d}{800\,d-1}$, there will be $\frac{m\,d-d}{m\,d-1}$: but as upon ſuppoſing the greateſt ſenſible exhauſtion of the ſphere, the denſity of the air remaining in it may be reckoned none, we ſhall have d (a number expreſſing the ratio of common air to included air) an infinite number; and thus $m\,d-1$ will become $m\,d$; and, therefore, for $\frac{m\,d-d}{m\,d-1}$, we ſhall have $\frac{m\,d-d}{m\,d}$, or $\frac{m-1}{m}$, the quantity d vaniſhing, by which the different denſities of the air are compared; the ratio, therefore, of the thickneſs of the metal to the radius of the ſphere, will be leſs than the ratio of $1-\overline{\frac{m-1}{m}\Big)}^{\frac{1}{3}}$ to unity. The ſame thing would have come out, if at firſt we had neglected the weight of the included air; nor ſhould we have occaſion for an infinite number; but ſuch a number was of uſe, that the caſes of rarefied and entirely exhauſted air might be comprized in one calculus.

The gravity of copper is about 9 times greater than that of water. It will therefore contain the gravity of common air 7200 times, and $\frac{m-1}{m}$ will be $\frac{7199}{7200}$, or $\frac{7199\times30}{8\times27\times1000}$, or 215970 divided by $8\times27\times1000$, where the cube root of the diviſor may be exactly extracted, and is $2\times3\times10$ or 60; and hence $\overline{\frac{m-1}{m}\Big)}^{\frac{1}{3}}$ will be the cube root of 215970 divided by 60; therefore, the cube root of $\frac{m-1}{m}$ will fall between $\frac{59997}{60000}$ and $\frac{59998}{60000}$; that is, $\frac{59997}{60000}$, will be leſs than the ſaid cube root, and $\frac{60000-59997}{60000}$, or $\frac{3}{60000}$; that is, $\frac{1}{20000}$ will be greater than $1-\overline{\frac{m-1}{m}\Big)}^{\frac{1}{3}}$, whoſe ratio to unity is greater than the ratio of the thickneſs of the metal to the radius of the ſphere; the ratio therefore of $\frac{1}{20000}$ to 1, or 1 to 20000 will be ſtill greater than the ratio of the thickneſs of the metal to the radius of the ſphere; the thickneſs of the metal, therefore, is to be aſſumed leſs, or if that be given, greater than the ſphere. Hence it follows, that the radius of the metalline ſphere will contain the thickneſs of the metal more than 20000 times, for the exhauſted ſphere to float in air; and, therefore, if the thickneſs of the metal be one inch, or 2 or 3 inches, the diameter of the metalline ſphere will be 3333, or 6666, or 9999 feet, and in the mean caſe, to wit, that of 2 inches and 6666 feet, the diameter of the ſphere will be more than 1000 paces; but if the radius of the ſphere were only 8 feet, as Franciſcus Lana would have it, the thickneſs of the metal ſhould have been $\frac{1}{2500}$ of a foot; that is, leſs than $\frac{1}{200}$ of an inch, which is impoſſible.

Nor is it, indeed, to be ſuppoſed that the thickneſs of 2 inches is ſufficient to ſuſtain the immenſe incumbent bulk of the air: for how could ſo ſmall a thickneſs ſuſtain a weight as great as that of water diffuſed for 1000 paces, and riſing to the height of 30 feet, which weight would be equal to that of air; and neither can that accurate uniformity of a ſpherical arch, which would be requiſite, be obtained in practice; and though it ſhould be granted, that by a thickneſs of the arch 2 or 3 times greater, its reſiſtance is more than 4 or 9 times, and thus in theory (that is, if we could actually perform what we conceive poſſible) the problem would at length be poſſible, yet in practice to form ſpheres of ſo immenſe a bulk, and that of metal, as copper or iron, does certainly exceed the power of all human ſkill.

ASCETICS, in eccleſiaſtical hiſtory, ſuch Chriſtians in the primitive church as inured themſelves to great degrees of abſtinence and faſting, in order to ſubdue their paſſions. In ſhort, every degree of uncommon piety laid claim to the title of aſcetic.

The word is formed from the Greek, *ασκητικα*, which is derived from *ασκεω*, to exerciſe.

ASCII, in geography, are the inhabitants of the torrid zone; becauſe, at certain times of the year, they have no ſhadow.

The word is compounded of the Greek, *α*, priv. and *σκια*, a ſhadow.

ASCITES, in medicine, the ſame with dropſy. See DROPSY.

ASCLEPIA, in antiquity, a feſtival of Æſculapius, the god of phyſic; and obſerved particularly at Epidaurus.

ASCLEPIAD, in ancient poetry, a ſpecies of verſe compoſed of four feet, the firſt of which is a ſpondee, the ſecond a choriambus, and the two laſt dactyls; or, of four feet and a cæſura, the firſt being a ſpondee, the ſecond a dactyl, then the cæſura, and after that the two dactyls, as

Mæcenas atavis edite regibus. Or,
Sublimi feriam ſidera vertice.

ASCLEPIODOTÆANS, in eccleſiaſtical hiſtory, a ſect of heretics that appeared in the time of the emperor Heliogabalus, and ſo called from their leader Aſclepiodotus, the firſt who taught that Jeſus Chriſt was a mere man.

ASCORDRUTÆ, in antiquity, a ſect of heretics in the ſecond century, who placed all religion in knowledge; and, under pretence of ſpiritual worſhip, refuſed every external or corporeal ſymbol.

ASCOLIA, in antiquity, a feſtival celebrated by the Athenian huſbandmen, in honour of Bacchus, to whom they ſacrificed a he-goat, becauſe that animal deſtroys the vines.

The word is Greek, and derived from *ασκος*, a bottle; it being cuſtomary at this feſtival to form the victim's ſkin into a kind of bottle, which was filled with oil and wine, and fell to the ſhare of him who firſt fixed himſelf upon it with one foot.

ASCUS, in natural hiſtory, the pouch, or bag of the opoſſum. See OPOSSUM.

ASELBES, a name given by ſome to the millepedes. See MILLEPEDES.

ASH, *Fraxinus*, in botany, a genus of trees, whoſe characters are: it hath pinnated leaves, which moſtly end in an odd lobe: the male flowers, which grow at a remote diſtance from the fruit, have no petals, but conſiſt in many ſtamina; the ovary becomes a ſeed-veſſel, containing one ſeed at the bottom, which is ſhaped like a bird's tongue.

There are ſix ſpecies of this tree; all which may be propagated by budding them into common aſh; upon which they will all take very well, and become hardier than upon their own ſtock: but theſe budded trees never grow ſo large as thoſe which are raiſed from ſeeds; nor will the ſtock and bud keep pace in their growth; ſo that there will be a remarkable difference in the ſize of the ſtem, and above the place where they are budded: but few of theſe foreign kinds have yet arrived at an age to produce ſeeds in England, the nurſery-gardeners having been obliged to propagate theſe ſorts by budding and grafting.

The common aſh is propagated by ſowing the keys in October or November, on a bed of freſh earth, which ſhould be well dug, and cleanſed from roots and noxious weeds. A ſmall bed will be ſufficient to raiſe a great quantity of theſe trees. The ſeeds ſhould be ſown pretty thick, and covered about half an inch thick with earth.

Theſe ſeeds, many times, continue until the ſecond ſpring before they come up; you ſhould, therefore, let the bed remain undiſturbed, and keep it clean from weeds. When your plants come up, you muſt alſo keep them very clear from weeds, and if the ſeaſon ſhould prove very dry, if you give them now and then a little water, it will greatly promote their growth. In this bed they ſhould remain no longer than the autumn following, provided they have grown well; at which time you ſhould prepare a nurſery, which ſhould be well dug and cleared, as before; then with your ſpade looſen the roots of the plants before you draw them up; otherwiſe you will endanger the breaking of them. When you have drawn them out of the ground, ſhorten the downright tap root; but do not cut off any of the lateral fibres; then, having prepared your ground, plant them in rows, three feet diſtance, row from row, and a foot aſunder in the rows, cloſing the earth to their roots with your feet.

In this nurſery they may remain two or three years, obſerving to keep them clear from weeds, as alſo to trim up the ſide branches every winter, and dig the ground between the rows; after which time you may remove them where they are to remain for good. This tree will grow upon almoſt any ſoil; but the better the ſoil is, the more the tree will increaſe in bulk. Notwithſtanding which, it ſhould not, by any means, be planted too near the other trees or plants; for it will exhauſt all the goodneſs of the ſoil from them; and the ſhade of this tree is malignant to moſt other plants. The diſtance they ſhould be planted is eight feet ſquare; and, after they have been planted one year, you may cut down every other tree, chooſing ſuch of them as are crooked, within ſix or eight inches of the ground; this will cauſe them to make many ſtrong, vigorous ſhoots; which, in ſeven or eight years time, will be fit for arbour poles, or to make hoops; and the other ſtraight trees may be ſuffered to grow for other timber; the number of which trees may be leſſened, as they increaſe in bulk, leaving ſtill the moſt promiſing ones to grow for larger timber.

If a wood of theſe trees is rightly managed, it will turn greatly to the advantage of its owner; for by the underwood, which will be fit to cut every ſeven or eight years, for the uſes abovementioned, there will be a continual income, more than ſufficient to pay the rent of the ground, and all other charges; and ſtill there will be a ſtock preſerved for timber, which, in a few years, will be worth forty or fifty ſhillings per tree.

This timber is of excellent uſe to the wheel-wrights and cartwrights for ploughs, axletrees, wheel-rings, harrows, bulls, oars, blocks for pullies, and many other purpoſes.

The beſt ſeaſon for felling of theſe trees is from November to February; for if it be done either too early in autumn, or too late in the ſpring, the timber will be ſubject to be infeſted with worms, and other inſects: but, for lopping of pollards, the ſpring is preferable for all ſoft woods.

ASHES, *Cineres*, the earthy particles of combuſtible ſubſtances after they have been burnt.

If the aſhes are produced from vegetable bodies, they contain a conſiderable quantity of fixt ſalt, blended with the terrene particles: and from theſe aſhes the fixed alkaline ſalts, called pot-aſh, pearl-aſh, &c. are extracted. See *Fixed* ALCALIES, POT-ASH, PEARL-ASH, &c.

The aſhes of all vegetables are vitrefiable, and found to contain iron. They are alſo an excellent manure for cold and wet grounds.

ASIA, one of the four grand diviſions of the earth, ſituated between 25 and 148 deg. of eaſt longitude; and between the equator and 72 deg. of north latitude. It is bounded on the north by the Frozen ocean; on the eaſt by the South-ſea; on the ſouth by the Indian ocean; and on the weſt by the Red-ſea, Mediterranean, &c. It is about 4800 miles in length, from eaſt to weſt, and 4300 in breadth, from north to ſouth.

Aſia is divided into three parts, diſtinguiſhed by the epithets, eaſtern, weſtern, and middle. The firſt comprehends the empire of China, Chineſe Tartary, and the Aſiatic Iſlands, lying to the ſouth and eaſt of China; the ſecond, or weſtern diviſion, comprehends Perſia, Arabia, Aſtracan, Circaſſin-Tartary, and Turkey in Aſia. The middle comprehends India, Uſbec-Tartary, Calmuc-Tartary, and Siberia.

Leſſer ASIA, the ſame with Natolia. See NATOLIA.

ASIATIC, ſomething peculiar to Aſia.

ASIATIC *Style*. See STYLE.

ASIDE, in the drama, ſomething ſaid by an actor, which ſome, or even all the other actors preſent, are ſuppoſed not to hear; a circumſtance juſtly condemned as being unnatural and improbable.

ASINUS, in natural hiſtory, the aſs. See ASS.

ASP, in natural hiſtory, a ſpecies of ſerpents often mentioned by the ancients, but without any accurate deſcription of it. Some ſay it is of the ſize of a common ſnake, but the back broader; and the neck ſwells greatly when the creature is angry. Some aſſert that their teeth grow exceeding long, and ſtand out of their mouths like thoſe of the boar; but this ſeems to be fabulous. However, it may be true, that two of the longeſt are hollow, and that they are thoſe which contain the venom. They are generally covered with thin pellicles, which ſlide down when the ſerpent bites. The ſkin is ſaid to be covered with ſcales, which are redder than thoſe of any other ſerpent; but others affirm they are of very different colours. Some ſay they are two cubits long, others four, and others again five; Peter Kolben affirms he has ſeen them ſeveral ells in length: ſo that, in ſhort, nothing certain can be known of the aſp. It is undoubtedly a native of Africa; and it was by the bite of one of theſe ſerpents that Cleopatra is ſaid to have ended her days.

Seba gives the name of aſp to ſeveral ſerpents, the firſt of which is ſaid to be found in Egypt, and is ſpotted with black. The ſkin is of a reddiſh aſh-colour, marked with black ſpots; whereas thoſe on the back nearly reſemble eyes. The head is of a dark brown, ſurrounded with a white colour; and the ſcales of the belly are white, adorned with a reddiſh border. He has alſo an American aſp, which nearly reſembles this in every reſpect.

The Java aſp is of a ſea-green, with a ſharp mouth, and a long head covered with ſcales on the fore-parts. The other ſcales are alſo of a ſea-green colour, with white edges, except under the belly, where they are of a light green, and ſeparated from the reſt by two white ſtreaks running like furrows along the ſides.

The Surinam aſp is of a bright green colour, ſprinkled with blackiſh ſpots; but the belly is of an aſh-coloured red, and the head is of a deep green; the eyes are lively, and the tail is terminated with ſharp points. *Brookes's Natural Hiſtory.*

ASPHALATHUM, in natural hiſtory, the ſame with lignum Rhodium. See LIGNUM *Rhodium.*

ASPARAGUS, in botany, the name of a genus of plants, whoſe flower is of the roſaceous kind, being uſually compoſed of ſix leaves, arranged in a circular form; from the center of the flower ariſes a piſtil, which finally becomes a ſoft fruit, or a roundiſh berry, containing a number of hard ſeeds. To this it may be added, that the leaves are always fine and ſlender.

The garden aſparagus is propagated by ſowing of the ſeeds; in the procuring of which you ſhould be particularly careful, ſince the goodneſs of your future crop, in a great meaſure, depends thereon: you ſhould, therefore, get it from ſome perſon of integrity; or, if you have any opportunity, ſave it yourſelf; or in ſome other neighbouring garden. You muſt look over the aſparagus-beds in the beginning of the ſeaſon, and mark ſome of the largeſt and faireſt buds with a piece of ſtick; which buds, when they have branched out, may be faſtened to ſtakes thruſt into the ground, to preſerve them from breaking. Theſe buds will, many of them, produce great numbers of red berries, which ſhould be ſuffered to remain upon the branches until the latter end of September, when the haulm will begin to decay; then cut off the branches, and ſtrip the berries into a tub, where they may lie in an heap to ſweat for three weeks, by which means the outer huſks will be rotten; then fill the tub with water, and with your hands break all the huſks, by ſqueezing them between your hands. Theſe huſks will all ſwim upon the water, but the ſeed will ſink to the bottom; ſo that, by pouring off the water gently, the huſks will be carried along with it; and by putting freſh water two or three times, and ſtirring your ſeed, you will make it entirely clean; then ſpread your ſeed upon a matt, and expoſe it to the ſun and air in dry weather, until it is perfectly dry, when you may put it into a bag, and hang it up in a dry place, till the beginning of February; at which time you muſt prepare a bed of good, rich earth, whereon you muſt ſow your ſeed; (but not too thick, which will cauſe your plants to be ſmall) and, having trod your ſeed into the ground, rake it over ſmooth.

In the following ſummer keep it diligently cleared from weeds, which will greatly add to the ſtrength of your plants; and toward the latter end of October, when the haulm is quite withered, you may ſpread a little rotten dung over the ſurface of the ground, about an inch thick, which will preſerve the young buds from being hurt by the froſts, &c.

In the ſpring following your plants will be fit to plant out for good; (for I would never chuſe plants of more than one year's growth, having very often experienced them to take much better than older, and to produce finer roots) you muſt therefore prepare your ground by trenching it well, burying therein a good quantity of rotten dung at the bottom of each trench, that it may lie at leaſt ſix inches below the ſurface of the ground: then level your whole plot very exactly, taking out all large ſtones; but this ſhould be done not long before you intend to plant your aſparagus, in which you muſt be governed according to the nature of your ſoil, or the ſeaſon; for if your ſoil is dry, and the ſeaſon forward, you may plant early in March; but, in a very wet ſoil, it is better to wait till the end of that month, or the beginning of April, which is about the ſeaſon that the plants are beginning to ſhoot. I know many people have adviſed the planting of aſparagus at Michaelmas; but this I have experienced to be very wrong; for in two different years I was obliged to tranſplant large quantities at that ſeaſon; but I had better thrown away the plants; for, upon examination in the ſpring, I found moſt of the roots mouldy, and decaying; and I am ſure, not one in five of them ſucceeded; and thoſe which did, were ſo weak as not to be worth their ſtanding.

The ſeaſon being now come, you muſt, with a narrow-pronged dung-fork, carefully fork up your roots, ſhaking them out of the earth, and ſeparating them from each other; obſerving to lay their heads even, for the more convenient planting them; which muſt be performed in this manner: Your plot of ground being levelled, you muſt begin at one ſide thereof, ranging a line very tight croſs the piece, by which you muſt throw out a trench exactly ſtraight, and about ſix inches deep; into which you muſt lay your roots, ſpreading them with your fingers, and placing them upright againſt the back of the trench, that the buds may ſtand forward, and be about two inches below the ſurface of the ground, and at twelve inches diſtance from each other; then, with a rake, draw the earth into the trench again, laying it very level, which will preſerve the roots in their right poſition: then remove your line a foot farther back, and make another trench in like manner, laying therein your plants, as before directed, and continuing the ſame diſtance row from row; only obſerving, between every four rows, to leave the diſtance of two feet four inches, for an alley to go between the beds, to cut the aſparagus, &c.

Your plot of ground being finiſhed and levelled, you may ſow thereon a ſmall crop of onions, which will not hurt your aſparagus; and tread in your ſeeds, raking your ground level. There are ſome perſons who plant the ſeed of aſparagus in the place where the roots are to remain; which is a very good method, if it be performed with care. The way is this: after the ground has been well trenched and dunged, they lay it level, and draw a line acroſs the ground, in the ſame manner as is practiſed for planting of the young plants; then, with a dibble, make holes at a foot diſtance, into each of which you muſt drop two ſeeds, for fear one ſhould miſcarry; theſe holes ſhould not be more than half an inch deep: then cover the ſeeds, by ſtriking the earth in upon it; and go on, removing the line a foot back for another row; and, after four rows are finiſhed, leave a ſpace for an alley between the beds, if it is deſigned to ſtand for the natural ſeaſon of cutting; but if it is to be taken up for hot-beds, there may be ſix rows planted in each bed; and the diſtance in the rows need not be more than nine inches. This ſhould be performed by the middle of February, becauſe the ſeeds lie long in the ground: but if onions are intended to be ſown upon the ground, that may be performed a fortnight or three weeks after, provided the ground is not ſtirred ſo deep as to diſturb the aſparagus-ſeeds, in raking the onion ſeed into the ground.

As the roots of aſparagus always ſend forth many long fibres, which run deep into the ground; ſo, when the ſeeds are ſown where they are to remain, theſe roots will not be broken or injured, as thoſe muſt which are tranſplanted; therefore, they will ſhoot deeper into the ground, and make much greater progreſs; and the fibres will puſh out on every ſide, which will cauſe the crown of the root to be in the center; whereas, in tranſplanting, the roots are made flat againſt the ſide of the trench.

When your aſparagus is come up, (which will be in three weeks or a month after planting) you muſt, with a ſmall hoe, cut up the weeds, and thin your crop of onions, where they may have come up in bunches; but this muſt be done carefully, and in dry weather, that the weeds may die as faſt as they are cut up. This work muſt be repeated about three times; which, if well done, and the ſeaſon not too wet, will keep the ground clear from weeds, until the onions are fit to be pulled up; which is commonly in Auguſt, and is known when their greens fall down. When you have drawn off your onions, you muſt clean your ground well from weeds; which will keep it clean till you earth your beds, which muſt be done in October, when the haulm begins to decay; for if you cut off the haulm, while green, the roots will ſhoot freſh again, which will greatly weaken them. This young haulm ſhould be cut off with a knife, leaving the ſtems two or three inches above-ground, which will be a guide to you to diſtinguiſh the beds from the alleys; then, with an hoe, clear off the weeds into the alleys, and dig up the alleys, burying the weeds in the bottom; and throw the earth upon the beds, ſo that the beds may be about five inches above the level of the alleys: then you may plant a row of coleworts in the middle of the alleys; but do not ſow or plant any thing upon the beds, which would greatly weaken the roots: nor would I ever adviſe the planting of beans in the alley (as is the practice of many), for it greatly damages the two outſide rows of the aſparagus. In this manner it muſt remain till ſpring, when you muſt hoe over the beds, to deſtroy all young weeds; then rake them ſmooth, and obſerve, all the ſucceeding ſummer, to keep them clear from weeds; and, in October, dig up the alleys again, as was before directed, earthing the beds, &c. The ſecond ſpring after planting, you may begin to cut ſome of your aſparagus, though it will be much better to ſtay until the third; therefore now you muſt fork up your beds with a flat-pronged fork, made on purpoſe, which is commonly called an aſparagus fork: this muſt be done before the buds ſhoot in the ſpring, and with care, leſt you fork too deep, and bruiſe the head of the root; then rake the beds over ſmooth, juſt before the buds appear above-ground; which will deſtroy all young weeds, and keep your beds clean much longer than if left unraked, or done ſo ſoon as forked: and when your buds appear about four or five inches above-ground, you may then cut them; but it ſhould be done ſparingly, only taking the large buds, and ſuffering the ſmall to run up to ſtrengthen the roots; for the more you cut, the more the roots will produce; but they will be ſmaller, and ſooner decay. When you cut a bud, you muſt open the ground with your knife, (which ſhould be very narrow and long in the blade, and filled with teeth like a ſaw) to ſee whether any more young buds are coming up cloſe by it, which might be either broken or bruiſed in cutting the other; then, with your knife, ſaw it off about three inches under-ground. This may appear a troubleſome affair to people unacquainted with the practical part; but thoſe who are employed in cutting aſparagus, will perform a great deal of this work in a ſhort time; but care in doing it is abſolutely neceſſary to be obſerved by all who cut aſparagus.

The manner of dreſſing your aſparagus-beds, is every year the ſame as directed for the ſecond; viz. keeping them from weeds, digging the alleys in October, and forking the beds towards the latter end of March, &c. only obſerve, every other year, to lay a little rotten dung, from a melon or cucumber-bed, all over your beds, burying ſome in the alleys alſo at the time for digging them up. This will preſerve your ground in heart, to maintain your roots in vigour; and, by this management, a plot of good aſparagus may be continued for ten or twelve years in cutting, and will produce good buds. *Miller's Gard. Dict.*

ASPECT, among gardeners, ſignifies the ſame with expoſure. See the article EXPOSURE.

The word is formed from the Latin, *aſpectus*, which is derived from *aſpicio*, to view.

ASPECT, in aſtronomy, denotes the ſituation of the planets and ſtars, with reſpect to each other.

There are five different aſpects. 1. Sextile aſpect is when the planets or ſtars are 60°. diſtant, and marked thus ✱. 2. The quartile, or quadrate, when they are 90°. diſtant, marked □. 3. Trine, when 120°. diſtant, marked △. 4. Oppoſition, when 180°. diſtant, marked ☍. And, 5. Conjunction, when both in the ſame degree, marked ☌.

Kepler, who added eight new ones, defines aſpect to be the angle formed by the rays of two ſtars meeting on the earth, whereby their good or bad influence is meaſured; for it ought to be obſerved, that theſe aſpects being firſt introduced by aſtrologers, were diſtinguiſhed into benign, malignant, and indifferent; the quartile and oppoſition being accounted malign; the trine and ſextile, benign or friendly; and the conjunction, indifferent.

Double ASPECT, in painting, is uſed where a ſingle figure is ſo contrived as to repreſent two or more different objects, either by changing the poſition of the eye, or by means of angular glaſſes.

ASPEN-TREE, in botany, the poplar with trembling leaves. See POPLAR.

ASPER, in grammar, an accent peculiar to the Greek language, marked thus, (ʻ) and importing that the letters over which it is placed, ought to be ſtrongly aſpirated, or pronounced as if an *h* was joined with them.

ASPER, or ASPRE, in commerce, a Turkiſh coin, three of which make a medine, and worth ſomething more than our halfpenny.

ASPERA *Arteria*, trachea, or wind-pipe, in anatomy, a large canal, partly cartilaginous, and partly membranous, ſituated anteriorly in the lower part of the neck, whence it runs down into the thorax, between the two pleuræ, through the upper ſpace left between the duplicature of the mediaſtinum, behind the thymus.

Having reached as low as the curvature of the aorta, it divides into two lateral parts, one toward the right hand, the other toward the left, which enter the lungs, and are diſtributed through their ſubſtance. Theſe two branches are called bronchia, and that on the right ſide is ſhorter than that of the left; whereas the right pulmonary artery is the longeſt.

The trachea is made up of ſegments of circles or cartilaginous hoops, diſpoſed in ſuch a manner, as to form a canal open on the back part, the cartilages not going quite round; but this opening is filled by a ſoft glandular membrane, which completes the circumference of the canal.

Each circle is about the twelfth part of an inch in breadth, and about a quarter of that ſpace in thickneſs. Their extremities are round; and they are ſituated horizontally above each other, ſmall interſtices being left between them, and the lower edge of the ſuperior ſegments being turned toward the upper edge of thoſe next below them.

They are all connected by a very ſtrong elaſtic membranous ligament fixed to their edges. The firſt three ſegments have been found united into one, bent alternately in two different places, according to its breadth. Sometimes two are continuous in the ſame manner.

The canal of the aſpera arteria is lined on the inſide by a particular membrane, which appears to be partly fleſhy or muſcular, and partly ligamentary, perforated by an infinite number of ſmall holes, more or leſs imperceptible, through which a mucilaginous fluid continually paſſes, to defend the inner ſurface of the trachea againſt the acrimony of the air which we breathe.

This fluid comes from ſmall glandular bodies diſperſed through the ſubſtance of the membrane, but eſpecially from glands ſomething larger than the former, which lie on the outer or poſterior ſurface of that ſtrong membrane by which the circumference of the canal is compleated. The ſame ſtructure is obſervable in the ramifications of the trachea, from the greateſt to the ſmalleſt. *Winſlow's Anatomy.*

The aſpera arteria is, like the arteries of the human body, compoſed of three tunics or coats. Plate VI. *fig* 2. repreſents theſe membranes ſeparated from each other; *a*, the glandulous membrane; *b*, the vaſculous; *c*, the internal tunic.

ASPERIFOLIATE, or ASPERIFOLIOUS, among botaniſts, ſuch plants as are rough leaved, having their leaves placed alternately on their ſtalks, and a monopetalous flower divided into five parts. The bugloſs, borage, &c. are of this claſs.

The word is formed from the Latin, *aſper*, rough, and *folium*, a leaf.

ASPERITY, the inequality of the ſurface of any body, which hinders the hand from paſſing over it freely.

According to the teſtimony of blind perſons, we have reaſon to believe that every colour hath its particular degree of aſperity.

ASPERULA, woodruffe, in botany, a genus of plants, the flower of which conſiſts of one petal, divided into four ſegments at the limb; its fruit is compoſed of two roundiſh, dry berries, adhering together, in each of which is a ſingle ſeed of the ſame roundiſh ſhape.

The leaves and roots of this plant are eſteemed aperient and diuretic, and conſequently preſcribed in the jaundice, and obſtructions of the viſcera.

ASPHALITES, a term applied by ſome anatomiſts to the fifth vertebra of the loins. See the article VERTEBRÆ.

ASPHALTUM, *Bitumen Judiacum*, or Jews pitch, in natural hiſtory, a ſolid, light, bituminous ſubſtance, found floating on the ſurface of the Dead-ſea, and dug out of the earth in ſeveral parts of Egypt.

It is of a black colour on the outſide, and a deep ſhining black within: of very little taſte, and ſcarcely any ſmell, unleſs heated, when it emits a ſtrong pitchy one. It is not ſoluble either in vinous ſpirits or oils, and melts but imperfectly, and with difficulty, leaving, on being burnt, a large quantity of aſhes.

Abundance of virtues are attributed to this bitumen; but has for many years been diſregarded in this country. The watchmakers uſe a compoſition of aſphaltum, fine lamp-black, and oil of ſpike, or turpentine, for drawing the black figures on dial plates: and the engravers uſe a compoſition, in which aſphaltum is an ingredient, as a ground for their copper-plates, when they etch with aqua-fortis.

ASPHODELUS, aſphodel, in botany, a genus of plants, whoſe flower is liliaceous, conſiſting of a ſingle petal, divided into ſix ſegments; and its fruit is a globoſe-trilocular capſule, containing a number of triangular ſeeds, globular on one ſide.

All the ſorts of aſphodel are very pretty ornaments for a flower-garden; and, requiring very little trouble to cultivate them, are rendered more acceptable. They may be all propagated by ſeeds, which ſhould be ſown ſoon after they are ripe, on a warm border of freſh light earth. In the ſpring the plants will appear, when you ſhould carefully clear them from weeds; and, in dry weather, they muſt be frequently watered: if this be duly obſerved, the plants will have acquired ſtrength enough to be tranſplanted by the Michaelmas following; at which time you muſt prepare a bed of freſh earth in the flower-nurſery, into which you ſhould plant the roots, at about ſix inches diſtance every way; obſerving to plant them ſo low, that the top of the roots may be three or four inches under the ſurface of the bed: in this bed they may remain one year; during which time they ſhould be frequently refreſhed with water in dry weather, and muſt be kept very clear from weeds. In this time the roots, having acquired ſtrength enough to produce flowers the following year, ſhould at Michaelmas, when their leaves are decayed, be carefully taken up, and tranſplanted into the flower-garden; obſerving to place them in the middle of the borders, among other hardy kind of flowers, where, being properly intermixed, they will make an agreeable variety, and continue a long time in flower.

Theſe plants may alſo be propagated by parting their roots; but this muſt not be too often repeated, leſt it weaken the roots, and prevent their flowering ſo ſtrong as they otherwiſe would do. Once in three years will be often enough to tranſplant the roots; at which times you may ſeparate thoſe which are grown large, ſo as to make two or three roots of each: but do not part them too ſmall; for that will ſo weaken them, as to prevent their flowering the following ſummer. The beſt time to tranſplant theſe roots is at Michaelmas, juſt when their leaves begin to decay. *Miller's Gard. Dict.*

ASPHURELATA, in natural hiſtory, ſemi-metallic foſſils, which are fuſible by fire, but not malleable in the pureſt ſtate. There are five bodies belonging to this claſs of foſſils, each of which makes a diſtinct genus; namely, antimony, biſmuth, cobalt, zinc, and mercury, or quickſilver. See each under its proper article.

ASPIRATE, in grammar, an epithet applied to words marked with an aſper. See ASPER.

ASPIRATION, in grammar, the pronouncing a ſyllable with ſome vehemence; as we do in thoſe words which have the letter *h* before them; as *hear*, *heat*, *health*, &c.

ASPIS, or ASP, in natural hiſtory; ſee ASP.

ASPLENIUM, ſpleenwort or miltwaſte, in botany, a ſmall buſhy plant, growing in fiſſures of rocks and old walls; conſiſting of capillary blackiſh roots, and long narrow leaves, cut down to the rib, on each ſide, alternately, into a number of oblong obtuſe narrow ſections, with broad baſes. It has no ſtalk or flower: the ſeeds are a yellow powder produced on the backs of the leaves.

The leaves of ſpleenwort have an herbaceous, mucilaginous, roughiſh taſte, and no conſiderable ſmell: with ſolution of chalybeate vitriol, they ſtrike a blackiſh colour. They ſtand recommended as a pectoral, ſimilar to maidenhair, to which they have been frequently joined in infuſions and apozems; and likewiſe as an aperient in obſtructions of the viſcera. Mr. Morand relates, that there has lately been diſcovered in them an excellent diuretic virtue; that they were uſed with great ſucceſs by count d'Auteuil, a Spaniſh naval commander, againſt the gravel, with which he was violently tormented; that they have ſince come greatly into uſe at Paris, Verdun, and Grenoble; that from the obſervations made there, they appear to gently carry off ſand, cleanſe the kidneys, and allay pains in the urinary paſſages; and that the way of uſing them is, to drink infuſions of them in the morning as tea, with the addition of ſuch other medicines as particular caſes may require.

ASPOLATHUS, in botany, the ſame with acacia. See ACACIA.

ASPRE, or ASPER. See ASPER.

ASS, *Aſinus*, in natural hiſtory, a well known animal, whoſe internal parts and ſkeleton exactly reſemble thoſe of the horſe; but they may be readily diſtinguiſhed from each other by the firſt glance of the eye; for the head is larger in proportion to the body; the ears much longer, and the forehead and temples furniſhed with longer hair; the eyes are not ſo prominent, the lower eye-lid more flat, and the upper lip more pointed and pendent. Beſides, the withers are not ſo high, the back-bone generally ſtands more out, and the buttocks are higher than the withers: add to this, that the tail is without long hair, from the root to about three quarters of its length, tho' it is furniſhed with it at the extremity; the mane likewiſe is ſhorter.

The large head, the forehead and temples loaded with hair, the eyes ſunk into the head, and at a great diſtance from each other, with the muzzle prominent towards the end, give an air of ſtupidity to an aſs, that never appears in an horſe; nor is the ſhape, when taken all together, by far ſo beautiful as that of this noble animal; his paces likewiſe are quite different, and he is much more ſlow and ſluggiſh. Notwithſtanding all this, the aſs would be of great value, if horſes were not ſo common; and if he was taken as much care of, he would, in all probability, turn out to a much greater advantage than he does at preſent. But we muſt not forget that an aſs is not without ſome good qualities; for he ſeems to know his maſter, and can diſtinguiſh him from all other men, though he has been ever ſo ill treated; he alſo knows the roads he has been accuſtomed to, and can find them without a guide. He has good eyes, a fine ſmell, and an excellent ear. He walks, trots, and gallops like a horſe; but his pace in all other reſpects is much ſlower, and he is ſooner tired. The aſs brays in a very diſagreeable manner; the ſhe-aſs has a more ſhrill and piercing cry.

Of all animals that are covered with hair, the aſs is leaſt ſubject to vermin; which may perhaps proceed from the hardneſs and dryneſs of his ſkin; and for the ſame reaſon, he is leſs ſenſible of the ſtrokes of a whip, and the ſtinging of flies, than a horſe. The teeth fall out, and grow at the ſame age, and in the ſame manner as in a horſe, and he has the ſame marks in his mouth. Aſſes generally breed in May and June, and in the tenth month the milk appears in the dugs of the female; but ſhe does not foal till the twelfth month; ſeven days after which, ſhe is ready for the male again. She always brings forth one at a time: at leaſt there are few inſtances to the contrary.

The aſs, like the horſe, is three or four years in growing, and will live till twenty-five or thirty. They ſleep much leſs than a horſe, and never lie down for that purpoſe, unleſs they are very much tired. In general, they have much better health than a horſe, and are ſubject to fewer diſeaſes.

Travellers inform us, that there are two ſorts of aſſes in Perſia, one of which is uſed for burdens, they being ſlow and heavy; and the other, kept like horſes, for the ſaddle; for they have ſmooth hair, carry their heads well, and are much quicker in their motion; but when they ride them, they ſit nearer their buttocks than when on a horſe. They are dreſſed like horſes, and are taught to amble like them; but they generally ſlit their noſtrils to give them more room for breathing. Dr. Ruſſel likewiſe tells us, they have two ſorts in Syria, one of which is like ours, and the other very large, with remarkable long ears; but they are both put to the ſame uſe, that of carrying burdens.

The onager, or wild-aſs, has been, by ſome authors, confounded with the zebra, but very improperly, the latter being a diſtinct ſpecies; for the onager is not ſtreaked like the zebra, nor is his ſhape ſo beautiful. Some have alſo been of opinion, that the wild aſs is not a diſtinct animal from the common aſs; but all judicious travellers that have taken notice of them, affirm the contrary. They are ſaid to be very ſwift; and when they ſee a man, will make a bound, and immediately fly away: ſo that the only method of taking them, is by traps and gins. They have much the ſame ſhape as common aſſes, but are of a brighter colour, and a white liſt runs from the head to the tail. Of the hide of theſe aſſes, and particularly of that part next the rump, they make that excellent leather which we call ſhagreen, and which is put to ſo many curious uſes.

Asses *Milk*, the milk of the animal deſcribed in the preceding article.

When we examine more minutely into the medicinal virtue and diſpoſition of aſſes milk, it will appear to be poſſeſſed of ſeveral peculiar excellencies, which render it ſo exceedingly wholeſome. In the firſt place it is thinner than all other milks, and abounds with watery and ſerous ingredients.

Since it is known that many diſeaſes are cauſed by a groſſneſs and tenacity of the juices, which, as they paſs ſlowly through the finer veſſels, of which the principal emunctories and ſtrainers of the glands conſiſt, are apt to ſtop in thoſe narrow paſſages, fill them up, and occaſion obſtructions, it is very obvious and natural to conclude, that the uſe of aſſes milk, which abounds with ſerous and fluid particles, muſt be extremely proper to open the obſtructed veſſels, to attenuate the groſs and viſcid juices, and ſet them in an eaſy and free motion. Again, when we know that multitudes of diſtempers proceed from an acrid, ſalt, and corroſive ſtate of the fluids, we cannot but be aſſured that the thin ſerum of aſſes milk will not fail of diluting, ſoftening, and ſubduing them: though it muſt be allowed, at the ſame time, that the ſweet oily ſubſtance contributes much towards this effect, which embraces and involves the pointed particles of ſalt; and by this means the crude ill digeſted juices, being properly corrected, are, by the plentiful aſſiſtance of ſerum, conveyed in their due courſe through the veſſels appointed for ſecretion.

It is another extraordinary excellence of aſſes milk, that it contains but a ſmall proportion of the groſſer curdling ſubſtance. Not above two drams of a white ſweetiſh matter can be procured from eight ounces of aſſes milk; when, on the contrary, ten drams of curd may be procured from the ſame weight of cows milk. It is therefore evident, that the quantity of the groſs curdling ſubſtance is very ſmall in aſſes milk, when compared with other ſorts. For this reaſon it eaſily diffuſes itſelf into the minuteſt extremities of the blood-veſſels, thoroughly dilutes the vital juices, liquifies the ſluggiſh humours, and, when it has thus diſſolved them, conveys them off.

A third circumſtance that more ſtrongly evinces the ſalubrious quality of aſſes milk, is, that the ſhare of cheeſe-like ſubſtance which it contains, is extremely ſoft and tender, and never makes a groſs or firm curd. To make this evident, ſome aſſes milk was warmed, and ſprinkled with vinegar, in order to ſee if it would contract a thick conſiſtence; but nothing appeared of that ſort, except a few light thin flakes, floating here and there on the ſerum: when, on the contrary, cows milk, the inſtant it was mixed with an acid, condenſed into lumps of a conſiderable hardneſs, and fell to the bottom.

Now in all cures which are ſought by milk, nothing can be ſo hurtful and dangerous as to have it curdle in the ſtomach; to prevent which accident ought to be the phyſician's principal care and concern: for the miſchiefs occaſioned by a coagulation of milk in the ſtomach are very pernicious, and have been obſerved and cautioned againſt by the beſt authors. It is paſt diſpute therefore, that the milk is the moſt wholeſome and proper for medicinal uſes, which has leaſt tendency to curdle, which is the caſe with aſſes milk in the moſt remarkable degree.

A fourth, and a very valuable excellence in aſſes milk, is its exquiſite ſweetneſs, in which it exceeds all other ſpecies of milk, except the human: for you may extract from it a very large quantity of delicate taſted ſugar, or rather a thick ſubſtance reſembling manna, by the following proceſs: Boil twelve ounces of aſſes milk, in the month of July, over a gentle fire, and it will immediately produce a thick concretion very ſweet, weighing one ounce. Upon this, pour it into a glaſs with a pint of rain water, which, on being frequently ſhaken, almoſt diſſolves the maſs, leaving only a ſmall ſediment. The liquor muſt then be poured through filtrating paper, and ſet to evaporate. By this means you will obtain half an ounce of an honey-like ſubſtance, extremely ſweet and white.

As aſſes milk therefore contains ſo plentiful a proportion of ſweet ſalts, we cannot doubt but it has for that reaſon a very ſingular medicinal quality which cannot be expected in other kinds of milk: for this honey-like ſalt greatly ſoftens, checks, and moderates the acrimony of humours, whether acid or bilious; and, by gently irritating the fibres of the bowels, urges them to their office and operations. Hippocrates very juſtly obſerves, that aſſes milk diſpoſes to purging more than any other; and in another place adviſes, as a remedy for the fluor albus, firſt to occaſion a gentle purging by drinking aſſes milk, and then to change it for cows milk.

Hence we ſee the reaſon why ſo much benefit is often found by perſons of a conſumptive habit, from drinking aſſes milk.

ASSA Dulcis, and Foetida. See Asa.

ASSARON, or Omer, a meaſure of capacity, in uſe among the Hebrews, containing five pints.

ASSART, *Aſſertum*, in law, an offence committed in a foreſt, by pulling up the trees by the roots.

This is a greater treſpaſs than waſte; though a perſon may ſue out a licence to aſſart ground in a foreſt; that is, to render it arable: and hence ſome diſtricts are called aſſarted lands; and formerly the owners paid aſſart rents to the crown for them.

ASSASSIN, a perſon who kills another ſecretly, or by attacking his enemy unprepared. It is alſo applied to a perſon who, for the ſake of ſome ſtipulated reward, undertakes to murder a perſon to whom he is a ſtranger, in order to revenge the quarrel of another.

ASSAULT, in law, a violent injury offered to a man's perſon, being of a higher nature than battery; for it may be committed by offering a blow, or pronouncing a terrifying ſpeech.

Thus, in caſe a perſon threatens to beat another, or lies in wait to do it, if the other is hindered in his buſineſs, and receives loſs, it will be an aſſault for which an action may be brought, and damages recovered.

Not only ſtriking, but thruſting, puſhing, throwing ſtones, or even drink in the face of any perſon, are deemed aſſaults. But in all theſe caſes, a man may plead in his juſtification the defence of his perſon or goods, father, mother, wife, maſter, &c.

Assault, in the military art, implies a furious effort made to carry a fortified poſt, camp, or fortreſs, wherein the aſſailants do not ſcreen themſelves behind any works: while the aſſault laſts, the batteries ceaſe firing for fear of killing their own men.

ASSAY, in metallurgy, the trial of the goodneſs and purity of metals and metallic ſubſtances.

Assay *Oven*, or *Docimaſtical Furnace*, a furnace uſed in aſſaying metals.

It is conſtructed in the following manner: 1. Make with iron plates, a hollow quadrangular priſm, H, H, (plate XIV. *fig.* 1.) eleven inches broad, and nine inches high, ending at the top, in a hollow quadrangular pyramid I, ſeven inches high, and terminating in an aperture ſeven inches ſquare. But this priſm muſt be cloſed at the bottom with an iron plate A, which ſerves as a baſis. 2. Near the bottom make a door A, three inches high, and five inches broad, leading to the aſh-hole. 3. Above this, and about ſix inches from the baſe, make another door C, forming the ſegment of a circle, four inches broad at its baſis, and three inches and a half high in the middle. 4. Faſten three iron plates H, H, H, on the fore part of the furnace; let the lowermoſt of theſe plates, which is eleven inches long, and half an inch broad, be faſtened with rivets to the bottom and fore part of the furnace, in ſuch a manner, that there may be a groove ſo wide, between the upper edge of the ſaid plate, and the ſide of the furnace, that the ſliders B, B, of the lower door, may be moved eaſily backwards and forwards therein, by means of the handles O, O: theſe ſliders muſt be made of a thicker iron plate than the other parts of the furnace. The ſecond iron plate muſt be alſo faſtened with rivets in the ſpace between the two doors, and directly parallel to the former, in ſuch a manner, that both the upper and lower edge of it may form a hollow groove with the ſide of the furnace. The lower of theſe grooves ſerves to receive the upper edges of the ſliders B, B, that ſhut the lower door: the upper groove is to receive the inferior edges of the ſliders D, D, belonging to the door C. The third plate, which is like the firſt, muſt be riveted cloſe above the upper door, in ſuch a manner, that its lower ſide may form a groove with the ſide of the furnace. 5. Make two ſliders D, D, to ſlide in the above grooves, by means of the handles O, O. In theſe ſliders muſt be two holes near the top; the one, marked E, muſt be about one fifth of an inch broad, and one inch and a half long; the other, marked F, a circular aperture one inch high, and two inches broad. 6. Let five round holes one inch in diameter be bored in the furnace, two in the fore part marked G, G, and two in the back part, all at the height of five inches from the bottom, and each of them three inches and a half from the neareſt ſide of the furnace: and a fifth hole K, at the height of one inch above the top of the upper door C. 7. Let the inſide of the furnace be furniſhed with iron hooks, about three inches from each other, and projecting about half an inch, in order to faſten the lute, with which the inſide of the furnace muſt be covered. 8. Let a moveable hollow quadrangular pyramid M, three inches high, be fitted to the upper aperture L, of the furnace; ſeven inches broad at the baſe, and terminating at top in a circular tube N, three inches in diameter, two inches high, and the upper diameter ſomewhat leſs than the bottom. This prominent tube ſerves to ſupport a funnel or flue, fitted to it, and compoſed of iron plates, two feet high. This funnel is only neceſſary when a very ſtrong fire is required. The pyramidical cover M, muſt have two handles P, P, faſtened to it, in order to put it on, or take it off, as the operation may require. And to hinder this cover from being eaſily thrown down, let an iron plate be riveted to the right and left ſides of the upper part of the furnace, and turned down towards the inſide, ſo as to form a groove, into which the lateral edges of the cover may enter, and ſlide forwards and backwards at pleaſure. A ſquare ledge of thick iron plate muſt be faſtened to the top of the upper ledge of the lower door A, in order to ſupport the grate and lute. The grate muſt be compoſed of ſmall iron bars, half an inch thick, three fourths of an inch diſtant from each other, and placed edgeways on the ledge. The lute muſt be about three quarters of an inch thick, and compoſed of Windſor loam, or French clay, moiſtened with ox blood diluted with water. In order to perform an operation in this oven, two iron bars an inch thick, and of a proper length, muſt be thruſt through the four holes G, G, above deſcribed, in order to ſupport the muffle introduced through the upper aperture of the furnace.

ASSAYING, the art of diſcovering how much pure metal is contained in any ore; or the proportion of the ſeveral ingredients in any mixed metal. For the methods of aſſaying the ſeveral metals, &c. ſee the articles Gold, Silver, Lead, Copper, &c.

Assaying of weights and meaſures, implies the examining the ſeveral weights and meaſures by the Clerk of the market.

ASSAY-MASTER, an officer appointed by certain corporations, to make juſt aſſays of all gold and ſilver brought to him for that purpoſe, and make a true report thereof.

ASSEMBLY, in military affairs, implies the ſecond beating of the drum before a march, on which the ſoldiers ſtrike their tents, roll them up, and ſtand to arms.

ASSENT, *Aſſenſus*, in a general ſenſe, implies an agreement to ſomething propoſed or affirmed by another.

Royal Assent, the approbation given by the king to a bill in parliament, after which it becomes a law.

ASSIENTO, in commerce, a contract between the king of Spain and ſome other power for tranſporting negroes into the Spaniſh dominions in America.

The word is Spaniſh, and ſignifies a farm.

ASSIGN, in common law, a perſon to whom a thing is aſſigned or made over.

ASSIGNEE, in law, a perſon appointed by another to do an act, tranſact ſome buſineſs, or enjoy a particular thing.

Aſſignees may be appointed either by deed or by law: by deed, where the leſſee of a farm aſſigns the ſame to another; by law, where the law makes an aſſignee without any appointment of the perſon intitled; as an executor is aſſignee in law to the teſtator, and an adminiſtrator to an inteſtate. But when there is an aſſignee by deed, the aſſignee in law is not allowed.

ASSIGNING, in a general ſenſe, implies the making over the right of one perſon to another. In a particular ſenſe, it ſignifies the pointing out of ſomething, as an error, falſe judgment, or waſte: but in theſe caſes it muſt be ſhewn wherein the error is committed, where and how the judgment is unjuſt, and where the waſte is committed.

ASSIGNMENT, in law, the transferring the intereſt one has in a leaſe, or other thing, to another perſon.

ASSISE, in old law books, is defined to be an aſſembly of knights and other ſubſtantial men, together with the juſtice, in a certain place, and at a certain time: but the word in its preſent acceptation, implies a court, place, or time, when and where the writs and proceſſes, whether civil or criminal, are decided by judge and jury.

In this ſenſe, aſſiſe is either general or ſpecial; general, when judges go their reſpective circuits, with commiſſion to take all aſſiſe: ſpecial, when a commiſſion is granted to particular perſons for taking an aſſiſe upon one or two diſſeiſins only.

By magna charta, juſtices ſhall be ſent through every county, once a year, who, with the knights of the ſeveral ſhires, ſhall take aſſiſe of novel diſſeiſin. With regard to the general aſſiſe, all the counties of England are divided into ſix circuits, and two judges are aſſigned by the king's commiſſion to every circuit, who now hold the aſſiſes twice a year, in every county except Middleſex, and the counties palatine. Theſe judges have five ſeveral commiſſions. 1. Of oyer and terminer, by which they are empowered to try treaſons, felonies, &c. 2. Of goal-delivery, which empowers them to try every priſoner in goal, be his offence what it will. 3. Of aſſiſe, which gives them authority to do right upon writs, brought by perſons wrongfully thruſt out of their lands and poſſeſſions. 4. Of niſi prius, by which civil cauſes come to an iſſue in the courts of Weſtminſter, are tried in the vacation by a jury of twelve men, in the county where the cauſe of action ariſes. 5. A commiſſion of the peace in every county of the circuit: and all juſtices of the peace and ſheriffs are to attend upon the judges, otherwiſe they are liable to be fined.

Assise is alſo uſed in ſeveral other ſignifications; as 1. For a jury, where aſſiſes of novel diſſeiſin are tried, and the pannels of aſſiſe ſhall be arraigned. 2. For a writ iſſued for the recovery of things immoveable, of which a perſon and his anceſtors have been diſſeized. 3. For an ordinance or ſtatute: thus the aſſiſe of the foreſt is a ſtatute concerning orders to be obſerved in the king's foreſt. 4. For a quantity of wheat, bread, &c. preſcribed by the ſtatute.

Assise *of Novel Diſſeiſin*, is a writ that lies where a tenant in fee ſimple, fee tail, or for term of life, is put out and diſſeized of his lands, tenements, rents, common of paſtures, common way, &c.

Assise *of Mort d'Anceſtor* is a writ which lies where a perſon's father, mother, brother, &c. died, ſeized of lands and tenements in fee, and after either of their deaths a ſtranger abateth.

Assise *of Utrum* lieth for an eccleſiaſtic againſt a layman, or a layman againſt an eccleſiaſtic, for lands or tenements doubtful whether they be lay-fee or free-alms.

ASSIZE. See Assise.

ASSOCIATION, the act of aſſociating, or conſtituting a ſociety, or partnerſhip, in order to carry ſome ſcheme or affair with more advantage.

The word is Latin, *aſſociatio*, and compounded of *ad*, to, and *ſocio*, to join.

Association *of Ideas*, is where two or more ideas conſtantly and immediately follow one another, ſo that the one ſhall almoſt infallibly produce the other, whether there be any natural relation between them or not.

When there is a real affinity or connection between ideas, it is the excellence of the mind to be able to collect, compare, and range them in order in its enquiries: but, on the contrary, where there is none, nor any cauſe to be aſſigned for their accompanying each other, but what is owing to mere accident or habit, the aſſociation is unnatural, becomes a great imperfection, and is too often a principal ſource of error or wrong deductions in reaſoning.

Aſſociation, in law, is a writ or patent ſent by the king, either of his own motion, or at the ſuit of the plaintiff, to the judges of aſſiſe, to have others aſſociated with them to take the aſſiſe. Upon this patent of aſſociation, the king ſends his writ to the juſtices of aſſiſe, commanding them to admit thoſe that are ſo ſent.

ASSONANCE, in rhetoric and poetry, is where the words of a phraſe or verſe have nearly the ſame ſound, or termination, without making a proper rhyme: theſe are accounted vicious by the generality of critics, though the Romans ſometimes uſed them with elegance.

ASSUMPSIT, in law, a voluntary or verbal promiſe, whereby a perſon undertakes to perform ſome agreement, or pay a certain ſum to another.

Thus, where a man ſells goods to another, the law makes the aſſumpſit; and promiſes he ſhall pay for them.

ASSUMPTION, a feſtival in the Romiſh church, celebrated in honour of the miraculous aſcenſion of the Virgin Mary, body and ſoul, into heaven.

The word is Latin, *aſſumptio*, and compounded of *ad*, to, and *ſumo*, to take.

Aſſumption, in logic, is the minor or ſecond propoſition in a categorical ſyllogiſm.

Aſſumption is alſo ſometimes uſed to imply a conſequence drawn from the propoſitions which compoſe an argument.

ASSUMPTIVE *Arms*, in heraldry, are ſuch as a perſon has a right to aſſume in conſequence of ſome noble and gallant action.

ASSURANCE, or Inſurance. See Inſurance.

ASSURRITANI, in eccleſiaſtical hiſtory, a ſect of heretics, who made their firſt appearance in Africa during the reign of Conſtantius. They were a branch of the Donatiſts, and held that the Son was inferior to the Father, and the Holy Ghoſt inferior to the Son: they rebaptized thoſe who embraced their ſect; and aſſerted that good men only were within the pale of the church.

ASTAROTH, or Aſhtaroth, in antiquity, a goddeſs of the Sidonians.

The word is Syriac, and ſignifies ſheep, eſpecially when their udders are turgid with milk. From the fœcundity of thoſe animals, which in Syria continue to breed a long time, they formed the notion of a deity, whom they called Aſtaroth, or Aſtarte. See Aſtarte.

ASTARTE, the ſingular of Aſtaroth, a goddeſs of the Sidonians, and called, in Scripture, the Queen of Heaven.

This deity is ſaid to have conſecrated the city of Tyre by depoſiting in it a fallen ſtar: and hence, perhaps, came the notion of a ſtar, or globe of light, which at certain times darted from Mount Libanus, near her temple at Aphac, and plunged itſelf into the river Adonis.

Mr. Fourmont, who has endeavoured to trace moſt of the pagan divinities mentioned in Scripture, ſuppoſes the Sydonian Aſtarte or Aſtaroth, to be the ſame with the Rachel of the Bible; becauſe the former in the Syriac language implies ſheep, and the latter has the ſame ſignification in the Hebrew.

ASTATI, in eccleſiaſtical hiſtory, a ſect of heretics in the ninth century, the followers of one Sergius, who renewed the errors of the Manichees.

The word is Greek, αςατοι, and compounded of α, priv. and ιςημι, to ſtand firm; becauſe they were remarkable for their inconſtancy.

ASTERIA, in natural hiſtory, a beautiful pellucid gem of variable colours, when viewed in different lights. It is generally known among jewellers by the name of cat's-eye. See Cat's-Eye.

Aſteria is alſo the name of an extraneous foſſil, called in Engliſh the ſtar-ſtone. See Star-Stone.

ASTERISK, a mark or character in the form of a ſmall ſtar (*) placed over any word or ſentence, to render it more conſpicuous, or refer the reader to the margin, or elſewhere, for a quotation, explanation, or the like.

The word is a diminutive of the Greek, αςηρ, a ſtar.

ASTERISM, in aſtronomy, the ſame with conſtellation. See Constellation.

ASTERN, in navigation, any diſtance behind a ſhip, or in direct oppoſition to that point of the compaſs which ſhe ſtems, i. e. when north is a-head, ſouth is a-ſtern.

ASTHMA, in medicine, a painful, difficult, and laborious reſpiration, occaſioned by an intolerable ſtraightneſs of the præcordia, which, by impeding the free circulation of the blood through the lungs, endangers a ſuffocation.

The word is Greek, ασθμα, and derived from αω, to breathe.

There are ſeveral ſorts of aſthmas: one difficulty of breathing proceeds from corpulency, and a very full habit of body; and is moſt apparent after violent motion; but this is a ſlight diſorder, and free from all danger. The next is the pituitous aſthma, attended with a moiſt cough, and the bringing up pituitous matter; it attacks the patient at all hours, and in all poſitions of the body; and is owing to a plenty of a viſcid mucus, ſtuffing the veſiculæ of the lungs, and hindering the free ingreſs and egreſs of the air through them. Another is owing to the convulſive contraction of the parts deſigned for reſpiration, and proceeds from various cauſes, both within and without the thorax; and this is called the dry, flatulent, or convulſive aſthma.

The longer this diſeaſe continues, the more ſharp and violent all the ſymptoms become. The patient's body grows more coſtive, and the urine is thin and watery; moſt commonly the feet ſwell, then the hands, face, and back; there is a numbneſs of the arms; the countenance is wan and livid, or of a leaden colour: then comes on a little fever, which grows worſe in the evening; the whole body is cachectic, with an œdematous ſwelling of the feet; there is a dropſy of the breaſt, or an aſcites, or anaſarca; at leaſt there is a palſy on one ſide, or of the arm; or inſtead thereof, a palſy of the eye-lids. This diſeaſe is likewiſe called by ſome, a ſuffocating aſthma; by others the nervous aſthma.

When the diſeaſe is recent, and is owing only to the ſpaſmodic contraction of the præcordia, there are hopes of a cure; eſpecially if the matter of the gout, ulcers, and exanthemata, are ſent back to their proper ſeats. When the menſes or hæmorrhoids, which were ſtopped, return, it yields relief, and if the diſeaſe was not too far advanced, perfect health. If it is inveterate or ill-managed, it brings on a dropſy of the breaſt, obſtructions of the lower belly, œdematous ſwellings of the feet, a cachexy, and an univerſal dropſy. In general, all convulſive aſthmas portend a ſudden exit, or ſuffocation, eſpecially if there is a polypus of the heart; if it continues long, then the patient will die of the dropſy; in which caſe it will be ſoon fatal: when there is a ſlow fever, an unequal intermitting pulſe, a palſy of the arms, a continual palpitation of the heart, little urine, a ſyncope or ſwooning, then death is at hand. Some are carried off by an inflammation of the lungs, and the more grievous the diſeaſe, the more languid the pulſe. The aſthma, in old perſons, continues till death: that which is cauſed by a diſlocation of the vertebræ cannot be cured till they are reduced. The more violent the acceſſion, the longer it laſts, and the oftener it returns with a greater danger of ſuffocation.

In the paroxyſm, becauſe the body is generally bound, and the wind and humours are carried upwards, the ſpeedieſt aſſiſtance is from emollient and carminative clyſters.

If there is occaſion, it may be repeated two or three times: afterwards uſe frictions of the feet, which have an incredible efficacy; alſo let them be put into warm water; for the feet are almoſt always cold. When there is a violent ſpaſm about the præcordia, hot fomentations are neceſſary, or bladders filled with hot milk, and applied to the part affected; likewiſe nervous liniments are very uſeful, rubbed in with a warm hand.

Out of the fit, if it proceeds from too great a congeſtion of blood about the breaſt, or from a polypus of the heart, bleeding in the foot will be proper, as alſo ſcarifications; in a ſuppreſſion of the hæmorrhoids, leeches ſhould be applied to the anus; as alſo gentle laxatives to cleanſe the primæ viæ: likewiſe bodily motion, ſlender diet, and ſoft drink. If there are hypochondriacal or flatulent ſymptoms, then gentle laxatives will be the more neceſſary, together with clyſters. When the menſes or hæmorrhoids are ſuppreſſed, then nothing is better than the Bath waters, both for bathing and drinking; or the waters of Selters taken warm and mixed with milk.

When the aſthma proceeds from the driving back ſome impure matter from the ſkin, or from the drying up of ulcers, and the humour is tranſlated to the nervous parts of the breaſt, then gentle diaphoretics will be neceſſary to ſend it back to the ſuperficies of the body.

ASTRÆA, in mythology, the goddeſs of Juſtice. She was the daughter of Jupiter and Themis, and came down from heaven in the golden age; but when the manners of men became corrupt, ſhe left the earth and returned to heaven.

ASTREA, in aſtronomy, the ſame as Virgo. See VIRGO.

ASTRAGAL, in architecture, a ſmall round moulding, in the form of a ring, ſerving as an ornament at the tops and bottoms of columns.

Sometimes the aſtragal ſerves to ſeparate the faſciæ of the architrave; but then it is wrought in the form of a chaplet, compoſed of beads and berries. It is alſo uſed both above and below the liſts, adjoining immediately to the die or ſquare of the pedeſtal.

ASTRAGAL, in anatomy, the bone of the heel, having a convex head, articulated to the tibia by ginglymus.

ASTRAGAL, in gunnery, the cornice ring of a piece of ordnance.

ASTRAGULUS, milk-vetch, in botany, a genus of plants with a papilionaceous flower, and a bilocular-podded fruit, containing kidney-ſhaped ſeeds. It is ſaid to be diuretic, and to increaſe the milk of nurſes.

ASTRAL, ſomething belonging to, or connected with, the ſtars.

The word is formed from the Latin, *aſtrum*, which is derived from the Greek, *αϛηρ*, a ſtar.

ASTRAL *Year*, the ſame with ſyderial year. See YEAR.

ASTRINGENTS, among phyſicians, ſuch medicines as are of an aſtringent or binding quality.

The word is formed from the Latin, *ad*, to, and *ſtringo*, to bind.

Hoffman very judiciouſly obſerves, that aſtringents are very proper to reſtore a tone and elaſticity to the animal fibres, when debilitated by diſeaſes, intemperance, or accident: but they are very ſeldom proper without a previous attenuation of the juices, and a courſe of deobſtruent medicines; becauſe obſtructions are more firmly riveted, and the viſcid juices circulated with more difficulty, when the diameters of the veſſels are conſtricted by aſtringents.

ASTRORITES, the ſtar-ſtone, in natural hiſtory; ſee the article STAR-STONE.

ASTROLABE, among the ancients, ſignified the ſame with what we now call an armillary ſphere. See ARMILLARY *Sphere.*

The word is formed from the Greek, *αϛηρ*, a ſtar, and *λαμϐανω*, to take.

ASTROLABE is alſo a name for the ſtereographic projection of the ſphere, either on the plane of the equator, or the meridian.

ASTROLABE likewiſe implies an inſtrument formerly uſed for taking the altitude of the ſun or ſtars at ſea.

This inſtrument conſiſts of a braſs ring A B C D, (plate VII. *fig.* 6.) the limbs of which are divided into degrees and minutes. A moveable index F G, carrying two ſights, moves upon the center E; and at the zenith, or upper part of the inſtrument, is a ring A, to hang it by in time of obſervation. When you would uſe it, turn the index towards the ſun, that the rays may paſs freely through both ſights, and the fiducial edge of the index will cut the degrees of altitude on the divided limb. This inſtrument has been long laid aſide by navigators, the motion of the ſhip rendering it impoſſible to take altitudes by it to any uſeful degree of accuracy. Indeed the inſtrument called from its inventor Hadley's quadrant, has ſupplied the defects of all others, and is now univerſally uſed at ſea. See *Hadley's* QUADRANT.

ASTROLOGICAL, ſomething belonging to aſtrology.

ASTROLOGY, a fallacious art, pretending to foretel future events from the ſituation, different aſpects, &c. of the heavenly bodies.

The word is formed from the Greek, *αϛηρ*, a ſtar, and *λογος*, a diſcourſe.

Aſtrology may be divided into two branches, natural and judiciary; the former being the prediction of natural effects, as the changes of weather, winds, ſtorms, hurricanes, thunder, floods, earthquakes, &c. and the latter that which pretends to foretel moral events, or ſuch as have a dependence on the freedom of the will.

Natural aſtrology belongs to phyſiology, or natural philoſophy, and is only to be deduced à poſteriori from phænomena and obſervations. To this part Mr. Goad chiefly confines himſelf, in his two books of aſtrology, in which he pretends that inundations and an infinite number of phænomena of that kind may be explained from the contemplation of the ſtars. For this aſtrology alſo, Mr. Boyle has a juſt apology in his hiſtory of the air. But as for judicial or judiciary aſtrology, with all the idle conceits about the horary reign of planets, the doctrine of horoſcopes, the diſtribution of the houſes, the calculation of nativities, fortunes, good or bad hours of buſineſs, and the like fatalities, they are mere levities, and may be plainly confuted by phyſical reaſons, and are therefore juſtly rejected by all ſound philoſophers.

ASTRONOMICAL, ſomething relating to aſtronomy.

ASTRONOMICAL *Calendar*, an inſtrument engraved on copper plates, printed on paper, and paſted on a board, with a braſs ſlider carrying a hair, and ſhews by inſpection the ſun's meridian altitude, right aſcenſion, declination, riſing, ſetting, amplitude, &c. to a greater degree of exactneſs than the common globes.

ASTRONOMICAL *Hours*, the ſame with equal hours, twenty-four of which make a natural day.

ASTRONOMICAL *Quadrant*, an inſtrument contrived for taking the altitude, &c. of the heavenly bodies, in a very accurate manner. See *Aſtronomical* QUADRANT.

ASTRONOMICAL *Character.*	See	CHARACER.
ASTRONOMICAL *Month.*		MONTH
ASTRONOMICAL *Obſervation.*		OBSERVATION.

ASTRONOMICAL *Sector*, a very uſeful mathematical inſtrument, made by the late ingenious Mr Graham.

It is allowed that a micrometer is the moſt accurate and convenient inſtrument for obſerving the place of a planet or comet, when it happens to be near enough to any known ſtar, by taking the differences of its right aſcenſion and declination from thoſe of the ſtar: but this being frequently impracticable, by reaſon that many large places in the heavens are void of ſtars, whoſe places are known; it is neceſſary to have recourſe to moveable quadrants, or ſextants, furniſhed with teleſcopic ſights, for taking larger diſtances. But beſides the difficulty and charge of procuring good inſtruments of this kind, the great trouble and uncertainties, in obſerving with them, are very notorious, ariſing chiefly from the difficulty the obſervers find in making their obſervations and each teleſcope correſpond together at the ſame inſtant, while the inſtrument is following the diurnal motion of the heavens. The lovers of aſtronomy are therefore much obliged to the late ingenious Mr. George Graham, F.R.S. not only for many uſeful improvements in the mechaniſm of ſeveral aſtronomical inſtruments, but alſo for contriving a very commodious and accurate one for the purpoſe aforeſaid; that is, for taking ſuch differences of right aſcenſion and declination as are too large to be obſerved through a fixed teleſcope; and yet with equal facility and exactneſs too in proportion to the radius of the inſtrument.

Let A B (plate X. *fig.* 16.) repreſent an arch of a circle, containing ten or twelve degrees well divided, having a ſtrong plate C D for its radius, fixed to the middle of the arch at D: let this radius be applied to the ſide of an axis H F I, and be moveable about a joint fixed to it at F, ſo that the plane of the ſector may be always parallel to the

axis H I; which being parallel to the axis of the earth, the plane of the ſector will always be parallel to the plane of ſome hour-circle. Let a teleſcope C E be moveable about the center C of the arch A B, from one end of it to the other, by turning a ſkrew at G; and let the line of ſight be parallel to the plane of the ſector. Now, by turning the whole inſtrument about the axis H I, till the plane of it be ſucceſſively directed, firſt to one of the ſtars, and then to another, it is eaſy to move the ſector about the joint F, into ſuch a poſition, that the arch A B, when fixed, ſhall take in both the ſtars in their paſſage, by the plane of it, provided the difference of their declinations does not exceed the arch A B. Then, having fixed the plane of the ſector a little to the weſtward of both the ſtars, move the teleſcope C E by the ſkrew G; and obſerve, by a clock, the time of each tranſit over the croſs hairs, and alſo the degrees and minutes upon the arch A B, cut by the index at each tranſit; then, in the difference of the arches, the difference of the declinations, and by the difference of the times, we have the difference of the right aſcenſions of the ſtars.

The dimenſions of this inſtrument are theſe: the length of the teleſcope, or the radius of the ſector, is 2 ½ feet; the breadth of the radius, near the end C, is 1 ½ inch; and at the end D two inches. The breadth of the limb A B is 1 ½ inch; and its length ſix inches, containing ten degrees divided into quarters, and numbered from either end to the other. The teleſcope carries a nonius or ſubdividing plate, whoſe length, being equal to ſixteen quarters of a degree, is divided into fifteen equal parts; which, in effect, divides the limb into minutes, and, by eſtimation, into ſmaller parts. The length of the ſquare axis H I F is eighteen inches, and of the part H I twelve inches; and its thickneſs is about a quarter of an inch: the diameters of the circles are each five inches: the thickneſs of the plates, and the other meaſures, may be taken at the direction of a workman.

This inſtrument may be rectified, for making obſervations, in this manner: by placing the interſection of the croſs hairs at the ſame diſtance from the plane of the ſector, as the center of the object-glaſs, the plane deſcribed by the line of ſight, during the circular motion of the teleſcope upon the limb, will be ſufficiently true, or free from conical curvity; which may be examined by ſuſpending a long plumb-line at a convenient diſtance from the inſtrument; and by fixing the plane of the ſector in a vertical poſition, and then by obſerving, while the teleſcope is moved by the ſkrew along the limb, whether the croſs hairs appear to move along the plumb-line.

The axis *h f o* (*fig.* 17.) may be elevated nearly parallel to the axis of the earth, by means of a ſmall common quadrant; and its error may be corrected, by making the line of ſight follow the circular motion of any of the circum-polar ſtars, while the whole inſtrument is moved about its axis, *h f o*, the teleſcope being fixed to the limb: for this purpoſe, let the teleſcope *k l* be directed to the ſtar *a*, when it paſſes over the higheſt point of its diurnal circle, and let the diviſion cut by the nonius, be then noted: then, after twelve hours, when the ſtar comes to the loweſt point of its circle, having turned the inſtrument half round its axis, to bring the teleſcope into the poſition *m n*; if the croſs hairs cover the ſame ſtar ſuppoſed at *b*, the elevation of the axis *h f o* is exactly right; but if it be neceſſary to move the teleſcope into the poſition *u v*, in order to point to this ſtar at *c*, the arch *m u*, which meaſures the angle *m f u* or *b f c*, will be known; and then the axis *h f o* muſt be depreſſed half the quantity of this given angle, if the ſtar paſſed below *b*, or muſt be raiſed ſo much higher, if above it; and then the trial muſt be repeated till the true elevation of the axis be obtained. By making the like obſervations upon the ſame ſtar on each ſide the pole, in the ſix o'clock hour-circle, the error of the axis, toward the eaſt or weſt, may alſo be found and corrected, till the croſs hairs follow the ſtar quite round the pole: for ſuppoſing *a o p b c* to be an arch of the meridian (or in the ſecond practice of the ſix o'clock hour-circle) make the angle *a f p* equal to half the angle *a f c*, and the line *f p* will point to the pole; and the angle *o f p*, which is the error of the axis, will be equal to half the angle *b f c* or *m f u*, found by the obſervation; becauſe the difference of the two angles *a f b*, *a f c*, is double the difference of their halves *a f o* and *a f p*. Unleſs the ſtar be very near the pole, allowance muſt be made for refractions.

ASTRONOMICAL *Year*. See YEAR.

ASTRONOMY, the ſcience which treats of the heavenly bodies; their magnitudes, diſtances, motions, eclipſes, conjunctions, &c.

The word is formed from the Greek, *αϛηρ*, a ſtar, and *νομος*, a law or rule.

Of all the ſciences cultivated by mankind, aſtronomy is acknowledged to be, and undoubtedly is, the moſt ſublime, the moſt intereſting, and the moſt uſeful: for, by the knowledge derived from this ſcience, not only the bulk of the earth is diſcovered, the ſituation and extent of the countries and kingdoms upon it aſcertained, trade and commerce carried on to the remoteſt parts of the world, and the various products of ſeveral countries diſtributed for the health, comfort, and conveniency of its inhabitants; but our very faculties are enlarged with the grandeur of the ideas it conveys, our minds exalted above the low contracted prejudices of the vulgar, and our underſtandings clearly convinced, and affected with the conviction of the exiſtence, wiſdom, power, goodneſs, and ſuperintendency of the Supreme Being!

From this branch of knowledge we learn by what means or laws the Almighty carries on, and continues the admirable harmony, order, and connexion obſervable throughout the planetary ſyſtem; and are led by very powerful arguments to form the pleaſing deduction, that minds capable of ſuch deep reſearches, not only derive their origin from that adorable Being, but are alſo incited to aſpire after a more perfect knowledge of his nature, and a ſtricter conformity to his will.

By aſtronomy we diſcover that the earth is at ſo great a diſtance from the ſun, that if ſeen from thence it would appear no bigger than a point, although its circumference is known to be 25,020 miles: yet that diſtance is ſo ſmall, compared with the diſtance of the fixed ſtars, that if the orbit in which the earth moves round the ſun were ſolid, and ſeen from the neareſt ſtar, it would likewiſe appear no bigger than a point, although it is at leaſt 162 millions of miles in diameter: for the earth in going round the ſun is 162 millions of miles nearer to ſome of the ſtars at one time of the year than at another; and yet their apparent magnitudes, ſituations, and diſtances from one another ſtill remain the ſame; and a teleſcope which magnifies above 200 times does not ſenſibly magnify them; which proves them to be at leaſt four hundred thouſand times farther from us than we are from the ſun.

It is not to be imagined that all the ſtars are placed in one concave ſurface, ſo as to be equally diſtant from us; but that they are ſcattered at immenſe diſtances from one another through unlimited ſpace: ſo that there may be as great a diſtance between any two neighbouring ſtars, as between our ſun and thoſe which are neareſt to him: therefore an obſerver, who is neareſt any fixed ſtar, will look upon it alone as a real ſun; and conſider the reſt as ſo many ſhining points, placed at equal diſtances from him in the firmament.

By the help of teleſcopes we diſcover thouſands of ſtars which are inviſible to the naked eye; and the better our glaſſes are, ſtill the more become viſible: ſo that we can ſet no limits either to their number or their diſtances.

The ſun appears very bright and large in compariſon of the fixed ſtars, becauſe we keep conſtantly near the ſun, in compariſon of our immenſe diſtance from the ſtars: for a ſpectator placed as near to any ſtar as we are to the ſun, would ſee that ſtar a body as large and bright as the ſun appears to us: and a ſpectator as far diſtant from the ſun as we are from the ſtars, would ſee the ſun as ſmall as we ſee a ſtar, diveſted of all its circumvolving planets; and would reckon it one of the ſtars, in numbering them.

The ſtars being at ſuch immenſe diſtances from the ſun, cannot poſſibly receive from him ſo ſtrong a light as they ſeem to have; nor any brightneſs ſufficient to make them viſible to us: for the ſun's rays muſt be ſo ſcattered and diſſipated before they reach ſuch remote objects, that they can never be tranſmitted back to our eyes, ſo as to render theſe objects viſible by reflection. The ſtars therefore ſhine with their own native and unborrowed luſtre, as the ſun does; and ſince each particular ſtar, as well as the ſun, is confined to a particular portion of ſpace, 'tis plain that the ſtars are of the ſame nature with the ſun.

It is no ways probable that the Almighty, who always acts with infinite wiſdom, and does nothing in vain, ſhould create ſo many glorious ſuns, fit for ſo many important purpoſes, and place them at ſuch diſtances from one another, without proper objects near enough to be benefited by their influences. Whoever imagines they were created only to give a faint glimmering light to the inhabitants of this globe, muſt have a very ſuperficial knowledge of aſtronomy, and a mean opinion of the divine wiſdom; ſince, by an infinitely leſs exertion of creating power, the Deity could have given our earth much more light by one ſingle additional moon.

Inſtead then of one ſun and one world only in the univerſe, as the unſkilful in aſtronomy imagine, that ſcience diſcovers to us ſuch an inconceivable number of ſuns, ſyſtems, and worlds, diſperſed through boundleſs ſpace, that if our ſun, with all the planets, moons, and comets belonging to it were annihilated, they would be no more miſſed out of the creation than a grain of ſand from the ſea-ſhore; the ſpace they poſſeſs being comparatively ſo ſmall, that it would ſcarce be a ſenſible blank in the univerſe; although Saturn, the outermoſt of our planets, revolves about the ſun in an orbit of 4884 millions of miles in circumference, and ſome of our comets make excurſions upwards of ten thouſand millions of miles beyond Saturn's orbit; and yet, at that amazing diſtance, they are incomparably nearer to the ſun than to any of the ſtars, as is evident from their keeping clear of the attractive power of all the ſtars, and returning periodically by virtue of the ſun's attraction.

From what we know of our own ſyſtem, it may be reaſonably concluded that all the reſt are with equal wiſdom contrived, ſituated, and provided with accommodations for rational inhabitants.

To an attentive conſiderer, it will appear highly probable, that the planets, together with their attendants called ſatellites or moons, are much of the ſame nature with our earth, and deſtined for the like purpoſes: for they are ſolid opaque globes, capable of ſupporting animals and vegetables. Some of them are bigger, ſome leſs, and ſome much about the ſize of our earth. They all circulate round the ſun, as the earth does, in a ſhorter or longer time, according to their reſpective diſtances from him; and have, where it would not be inconvenient, regular returns of ſummer and winter, ſpring and autumn. They have warmer and colder climates, as the various productions of our earth require; and in ſuch as afford a poſſibility of diſcovering it, we obſerve a regular motion round their axis, like that of our earth, cauſing an alternate return of day and night, which is neceſſary for labour, reſt, and vegetation, and that all parts of their ſurfaces may be expoſed to the rays of the ſun.

Such of the planets as are fartheſt from the ſun, and therefore enjoy leaſt of his light, have that deficiency made up by ſeveral moons, which conſtantly accompany and revolve about them, as our moon revolves about the earth. The remoteſt planet has, over and above, a broad ring encompaſſing it, which, like a lucid zone in the heavens, reflects the ſun's light very copiouſly on that planet: ſo that if the remoter planets have the ſun's light fainter by day than we, they have an addition made to it morning and evening by one or more of their moons, and a greater quantity of light in the night time.

On the ſurface of the moon, becauſe it is nearer us than any other of the celeſtial bodies are, we diſcover a nearer reſemblance of our earth: for by the aſſiſtance of teleſcopes we obſerve the moon to be full of high mountains, large valleys, and deep cavities. Theſe ſimilarities leave us no room to doubt but that all the planets and moons in the ſyſtem are deſigned as commodious habitations for creatures endowed with capacities of knowing and adoring their beneficent Creator.

Since the fixed ſtars are prodigious ſpheres of fire, like our ſun, and at inconceivable diſtances from one another, as well as from us, it is reaſonable to conclude they are made for the ſame purpoſes that the ſun is; each to beſtow light, heat, and vegetation, on a certain number of inhabited planets, kept by gravitation within the ſphere of its activity.

What an auguſt! what an amazing conception, if human imagination can conceive it, does this give of the works of the Creator! Thouſands of thouſands of ſuns, multiplied without end, and ranged all around us, at immenſe diſtances from each other, attended by ten thouſand times ten thouſand worlds, all in rapid motion, yet calm, regular, and harmonious, invariably keeping the paths preſcribed them; and theſe worlds peopled with myriads of intelligent beings, formed for endleſs progreſſion in perfection and felicity.

If ſo much power, wiſdom, goodneſs, and magnificence, is diſplayed in the material creation, which is the leaſt conſiderable part of the univerſe, how great, how wiſe, how good muſt he be, who made and governs the whole!

It is not to be doubted but aſtronomy was invented from the beginning of the world. As there is nothing more ſurpriſing than the regularity of thoſe great luminous bodies, that turn inceſſantly round the earth, it is eaſy to judge, that one of the firſt curioſities of mankind was to conſider their courſes, and to obſerve the periods of them. But it was not curioſity only that induced men to apply themſelves to aſtronomical ſpeculations: neceſſity itſelf may be ſaid to have obliged them to it: for if the ſeaſons are not obſerved, which are diſtinguiſhed by the motion of the ſun, it is impoſſible to ſucceed in agriculture. If the times proper for making voyages were not previouſly known, commerce could not be carried on. If the duration of the month and year were not determined, a certain order could not be eſtabliſhed in civil affairs, nor the days allotted to the exerciſe of religion be fixed. Thus, as neither agriculture, commerce, polity, nor religion could diſpenſe with the want of aſtronomy, it is evident that mankind were obliged to apply themſelves to that ſcience from the beginning of the world.

What Ptolomy relates of the obſervations of the heavens, by which Hipparchus reformed aſtronomy almoſt two thouſand years ago, proves ſufficiently, that, in the moſt ancient times, this ſcience was much ſtudied.

It is agreed that aſtronomy was cultivated in a particular manner by the Chaldeans. The height of the tower of Babel, which the vanity of men erected about an hundred and fifty years after the Flood, the level and extenſive plains of that country, the nights in which they breathed the freſh air after the troubleſome heats of the day, an unbroken horizon, a pure and ſerene ſky, all conſpired to engage that people to contemplate the vaſt extent of the heavens, and the motions of the ſtars. From Chaldea aſtronomy paſſed into Egypt, and ſoon after was carried into Phœnicia, where they began to apply its ſpeculative obſervations to the uſes of navigation, by which the Phœnicians ſoon became maſters of the ſea and of commerce.

What made them bold in undertaking long voyages, was their cuſtom of ſteering their ſhips by the obſervation of one of the ſtars of the little bear, which being near the immoveable point of the heavens called the pole, is the moſt proper to ſerve as a guide in navigation. Other nations, leſs ſkilful in aſtronomy, obſerved only the great bear in their voyages: but as that conſtellation is too far from the pole to be capable of ſerving as a certain guide in long voyages, they did not dare to ſtand out ſo far to ſea as to loſe ſight of the coaſts: and if a ſtorm happened to drive them into the ocean, or upon ſome unknown ſhore, it was impoſſible for them to know by the heavens into what part of the world the tempeſt had carried them.

Thales, having at length brought the ſcience of the ſtars from Phœnicia into Greece, taught the Greeks to know the conſtellation of the little bear, and to make uſe of it as their guide in navigation. He alſo taught them the theory of the motion of the ſun and moon, by which he accounted for the length and ſhortneſs of the days, determined the number of the days of the ſolar year, and not only explained the cauſe of eclipſes, but ſhewed the art of foretelling them, which he even reduced to practice, foretelling an eclipſe which happened ſoon after. The merit of a knowledge ſo uncommon in thoſe days, made him paſs for the oracle of his times, and occaſioned his being given the firſt place amongſt the ſeven ſages of Greece.

Anaximander was his diſciple, to whom Pliny and Diogenes Laertius aſcribe the invention of the terreſtrial globe; or, according to Strabo, geographical maps. Anaximander is ſaid alſo to have erected a gnomon at Sparta, by the means of which he obſerved the equinoxes and ſolſtices, and to have determined the obliquity of the ecliptic more exactly than had ever been done before; which was neceſſary for dividing the terreſtrial globe into five zones, and for diſtinguiſhing the climates, that were afterwards uſed by geographers for ſhewing the ſituation of all the places of the earth. The Greeks, aſſiſted by the inſtructions they had received from Thales and Anaximander, ventured to make conſiderable voyages, and planted ſeveral colonies in remote countries.

Aſtronomy was ſoon ſatisfied for the aſſiſtance ſhe had given to navigation: for commerce having induced the learned of Greece to viſit other nations, they greatly increaſed their knowledge from converſing with the Egyptian prieſts, who had long made the ſcience of the ſtars their profeſſion. They alſo learned many things from the Pythagorean philoſophers in Italy, who had made ſo conſiderable a progreſs in this ſcience, that they had rejected the common opinions, and aſſerted that the earth and planets moved round the ſun, which was at reſt in the center of the ſyſtem.

Meton greatly diſtinguiſhed himſelf at Athens by his profound knowledge in aſtronomy. He lived in the time of the Peloponneſian war; and when the Athenians were fitting out a fleet againſt Sicily, he pretended madneſs, in order to avoid having any ſhare in that expedition, which he was perſuaded would be attended with fatal conſequences. He was the inventor of the golden number, ſtill placed in the calendar.

The Greeks alſo improved their knowledge from converſing with the druids, who, according to Julius Cæſar, inſtructed their pupils in the knowledge of the ſtars, and the magnitude of the heavenly bodies.

This ſpecies of learning was more ancient in Gaul than is generally imagined. Strabo has preſerved a famous obſervation, made by Pytheas at Marſeilles about two thouſand years ago, with regard to the proportion of the ſun's ſhadow to the height of a gnomon at the time of the ſolſtice. Were the circumſtances of this obſervation exactly known, it would be ſufficient to reſolve the important queſtion, Whether the obliquity of the ecliptic be or be not ſubject to variation?

Pytheas was not contented with making obſervations in his own country. His paſſion for aſtronomy and geography induced him to travel through Europe, from the pillars of Hercules to the mouths of the Tanais. He alſo advanced along the ſhore of the weſtern ocean, towards the north pole, and obſerved that the days grew longer about the ſummer ſolſtice, in proportion as he travelled; ſo that, in the iſland of Thule, the ſun roſe almoſt as ſoon as it ſet, the tropic continuing entirely above the horizon. By this means he proved the fallacy of what ſome philoſophers had advanced, namely, that thoſe climates were not inhabitable; and at the ſame time ſhewed the method of diſtinguiſhing the climates by the length of the days and nights.

About the time of Pytheas, ſeveral of the Grecians applied themſelves to aſtronomy in emulation of each other. Eudoxus, the diſciple of Plato, not being ſatiſfied with what was taught on that ſubject in the ſchools of Athens, repaired to Egypt, to cultivate aſtronomy at its ſource; and having a letter of recommendation from Ageſilaus king of Sparta, to Nectanebus king of Egypt, he remained ſixteen months with the aſtronomers of that country. At his return he compoſed ſeveral books upon aſtronomy, and, among others, a deſcription of the conſtellations, which Aratus, ſome time after, turned into verſe, by order of Antigonus.

Ariſtotle, at once the diſciple of Plato, and the cotemporary of Eudoxus, made uſe of aſtronomy for improving phyſics and geography. He attempted to determine, by means of aſtronomical obſervations, both the figure and magnitude of the earth. He demonſtrated, that it was of a ſpherical form by the circular appearance of its ſhadow on the diſk of the moon in eclipſes, and from the inequality of the meridian altitudes of the ſun, which are different in different latitudes.

Calliſthenes, who attended Alexander the Great, having been ſent to Babylon, found there aſtronomical obſervations, made by the Babylonians during the ſpace of nineteen hundred and three years, and ſent them to Ariſtotle.

The princes who ſucceeded Alexander in the kingdom of Egypt, were very careful to draw the moſt famous aſtronomers to their courts by their liberality; ſo that Alexandria ſoon became the ſeat of aſtronomy. The famous Conon made a vaſt number of obſervations; but they have not reached our hands. Ariſtyllus and Timochares obſerved the places of the fixed ſtars, in order to improve navigation and geography. Eratoſthenes meaſured a degree of the meridian, in order to determine the magnitude of the earth. Hipparchus, who alſo reſided at Alexandria, laid the foundation for a methodical ſyſtem of aſtronomy; for a new ſtar happening to appear, he made a catalogue of the fixed ſtars, conſiſting of two thouſand and twenty-two. He alſo deſcribed their motion round the poles of the ecliptic, and at the ſame time applied himſelf to eſtabliſh a theory of the ſolar and lunar motion.

The Romans, who aſpired to the empire of the world, encouraged aſtronomy, and endeavoured to carry it nearer to perfection; and in the reign of Antoninus it began to aſſume a new face: for Ptolemy, who may be called the reſtorer of this ſcience, improving from the lights of his predeceſſors, and adding the obſervations of Hipparchus, Timochares, and thoſe of the Babylonians to his own, compoſed a ſyſtem of aſtronomy, entitled, "The "Great Syntaxis." It contained the theory and tables of the motion of the ſun, moon, and other planets, and of the fixed ſtars.

But as the beginnings of great works are never perfect, it is no wonder that Ptolemy's work was not free from errors and defects. Many ages, however, elapſed without any one's preſuming either to correct or complete it. At laſt the Arabian princes, having conquered the countries where aſtronomy had long flouriſhed, procured the work of Ptolemy to be tranſlated into their own language, and called it the Almageſt. Nor did they ſtop here; they cauſed many obſervations to be made, by which it appeared, that the greateſt declination of the ſun was one-third of a degree leſs than what Ptolemy had made it; and that the motion of the fixed ſtars was not ſo ſlow as he believed it. They alſo ordered a large extent of country under the ſame meridian to be meaſured, in order to determine the length of a degree.

This example of the caliphs excited the princes of Europe to promote the improvement of aſtronomy. The emperor Frederic the ſecond, willing that the Chriſtians ſhould underſtand aſtronomy as well as the Barbarians, cauſed the Almageſt of Ptolemy to be tranſlated from the Arabic into Latin; and Alphonſo, king of Caſtile, aſſembled the moſt able aſtronomers from all parts. By his orders they applied themſelves to reform aſtronomy, and compoſe new tables, which from him were called the Alphonſine Tables.

This work awaked the curioſity of the learned of Europe; they applied themſelves to invent inſtruments for facilitating the obſervations of the heavenly bodies; they calculated ephemerides, and compoſed tables for finding the declinations of the planets; and laboured ſucceſsfully to facilitate the calculation of eclipſes. The noble Dane Tycho Brahe was a far more accurate obſerver than any that preceded him. He publiſhed from his own obſervations, a catalogue of 770 fixed ſtars; and Nicholaus Copernicus revived the ancient Pythagorean ſyſtem.

John Kepler, a moſt excellent aſtronomer, diſcovered, by the help of Tycho's labours, the true ſyſtem of the world, and the laws that regulate the motions of the celeſtial bodies. Galileo, the Florentine philoſopher, firſt directed a teleſcope to the heavens, and by the aſſiſtance of that inſtrument diſcovered a great many new and ſurprizing phænomena, as the ſatellites of Jupiter, and their motion, the various phaſes of Saturn, the increaſe and decreaſe of the light of Venus, the mountains and uneven ſurface of the moon, the ſpots of the ſun, and the revolution of that luminary about its own axis.

Hevelius has given us a catalogue of the fixed ſtars, much larger than that of Tycho, compoſed from his own curious obſervations. Huygens and Caſſini firſt ſaw the ſatellites of Saturn, and diſcovered his ring. The indefatigable Mr. Flamſteed watched the motion of the ſtars for more than forty years; and has obliged the world with ſuch accurate obſervations on the motions, &c. of the different luminaries, as will tranſmit his name to the lateſt poſterity; he alſo publiſhed what is called the Britannic catalogue of fixed ſtars, containing above three thouſand ſtars, from his own obſervations.

The immortal Sir Iſaac Newton, beſides his other innumerable and amazing inventions, diſcovered the fountain and ſpring of all the celeſtial motions, and the law which the great Author has infuſed through the whole ſyſtem, and commanded all bodies to obſerve; namely, that all the particles of matter attract one another in a reciprocal duplicate proportion of its diſtance.

This law may be conſidered as the cement of nature, the principle of union, which preſerves every thing in its proper ſtate and order; it detains not only the planets, but even the comets within due bounds, and hinders them from making too long incurſions into the immenſe regions of ſpace.

To the ſame genius we are alſo obliged for the diſcovery of the law that regulates all the heavenly motions, and ſets bounds to the planets orbs. He ſhewed us the cauſe why ſuch a conſtant and regular proportion is obſerved by both primary and ſecondary planets, in their circulations round their central bodies, in comparing their diſtances with their periods; and why all the celeſtial motions are ſtill continued in ſuch amazing regularity, harmony, and order.

The great Dr. Halley has obliged the world with the aſtronomy of comets, a catalogue of the ſouthern ſtars, aſtronomical tables, &c.

Other Aſtronomical writers are, Albategnius, Sacro Boſco, Regio Montanus, Purbachius, Lanſbergius, Longomontanus, Clavius, Boyer, Dr. Hook, Ricciolus, Horrox, Sir Jonas Moore, Tacquet, Bullialdus, Seth Ward, count Pagan, Wing, Street, De la Hire, Dr. Gregory, Mercator, Whiſton, Dr. Keil, the two Caſſini's, Leadbetter, Hodgſon, Brent, Dr. Long, the Abbe le Caille, Wright, Ferguſon, De la Lande, &c.

ASTRONOMY is ſometimes divided into the *old* and the *new*.

The Old ASTRONOMY is that which ſuppoſes the earth fixed and quieſcent in the center, and that the heavenly bodies perform their revolutions round it. This hypotheſis is followed by Ptolemy in his Almageſt, and thence called the Ptolemaic Syſtem. See the article PTOLEMAIC *Syſtem*.

The New ASTRONOMY is that which has been generally followed ſince the time of Copernicus, who revived the Pythagorean or true ſolar Syſtem. See COPERNICAN *Syſtem*.

ASTROSCOPE, the name of an inſtrument compoſed of two hemiſpheres, having the conſtellations delineated on their ſuperficies.

The word is formed from the Greek αϛηρ, a ſtar, and σκοπεω, to view.

ASTYNOMI, in antiquity, magiſtrates at Athens, whoſe office was the ſame with that of the ædiles at Rome. See ÆDILE.

ASYLUM, a ſanctuary, a place of refuge, or protection.

Servius derives the word from the privative α, and συλαω, to draw out; becauſe no perſon could be taken by force from an aſylum.

Some pretend, the firſt aſylum in Greece was that eſtabliſhed by order of the oracle of Jupiter Dodonæus, which commanded the Athenians to grant their lives to all thoſe who fled for refuge into the Areopagus, or to the altars of the goddeſſes. But others ſay, the firſt aſylum was built at Athens by the Heraclidæ, and was a refuge for thoſe who fled from the oppreſſion of their fathers.

The aſyla of altars and temples were very ancient in the time of Pauſanias, who writes, that Neoptolemus, the ſon of Achilles, was ſlain near the altar of Apollo at Delphi, as a juſt puniſhment for his having killed Priam, king of Troy, who had fled to the altar of Jupiter Hercules for refuge. The temple of Diana at Epheſus was the moſt famous aſylum. Strabo tells us, that ſeveral princes allowed it, ſome a greater, others a leſs extent of ground beyond the temple itſelf: and Herodotus tells us, there was a temple of Hercules in Egypt, to which bondſlaves fled; who, after they had taken upon them the badges of that god, could not be retaken by their maſters: for the privileges of the aſyla were inviolable; whence Tacitus complains that the Grecian temples were filled with the worſt of ſlaves, with inſolvent debtors, and criminals who fled from juſtice, and that no authority was ſufficient to force them from thence.

This privilege began to be enjoyed by the Chriſtian churches about the time of Conſtantine; but whether that prince made any laws concerning it, is doubted by learned men; for none appear that are older than the time of Theodoſius. At firſt, only the altar and inward fabric of the church was a place of refuge; but afterwards any outer buildings, or precincts of the church, had the ſame privilege granted them; ſuch as the houſes or lodgings of the biſhop and clergy, gardens, baths, courts, and cloyſters; and, in after-ages, this exemption was extended to the graves and ſepulchres of the dead, to croſſes, ſchools, monaſteries, and hoſpitals. This privilege, originally, was not intended to patronize wickedneſs, or ſcreen the guilty from juſtice; but as a refuge for the innocent, the injured, and the oppreſſed; or, in doubtful caſes, to give men protection, till they might obtain an equitable and fair hearing: in all ſuch caſes they were allowed thirty days protection. But that no one might expect this indemnity who had not a juſt and legal title to it, ſeveral crimes and caſes were excepted by law, for which the church could grant no protection: at firſt, protection was denied to public debtors, who had either embezzled, or kept back by fraud, the public revenues of the ſtate. Secondly, to Jews, who pretended to turn Chriſtians only to avoid paying their debts, or ſuffering legal puniſhment for their crimes; in other caſes, they had the common benefit of the ſanctuary with other men. The third ſort of perſons to whom this privilege was denied, were heretics and apoſtates; the fourth, ſlaves who fled from their maſters: and the fifth, robbers, murderers, conſpirators, raviſhers, adulterers, and other criminals of the like nature. This ſhews, that the original intention of ſanctuaries in the Chriſtian church was only to protect the innocent and injured; and, in dubious caſes, to grant the ſuppoſed offender a little reſpite. The conditions upon which protection was granted, were, firſt, not to fly with arms to the church; ſecondly, to raiſe no clamour or tumult in flying thither; and thirdly, not to eat, or lodge in the church, but to be entertained in ſome outward building.

Modern ſanctuaries are a great abuſe of theſe ancient aſyla of the Chriſtian church, in giving protection to almoſt all ſorts of criminals, and ſo enervating the force of civil laws. The canon-law of Gratian, and the decretals of the popes, grant protection to all criminals, except houſe-breakers, highwaymen, and ſuch as commit enormous crimes in the church itſelf, upon preſumption of its protection. Polydore Virgil cenſures the Engliſh for granting protection to all ſorts of criminals, not excepting traitors and rebels: but at preſent we have no ſuch practice; nor is any privileged place, or ſanctuary, in England, allowed, by law, to ſcreen offenders from juſtice.

ASSYMMETRY, the want of proportion between the parts of any thing; being the oppoſite to ſymmetry.

The word is Greek, and compounded of α, priv. συν, and μετρον, meaſure.

It is ſometimes uſed by mathematicians to ſignify incomprehenſibility, or when there is no common meaſure between two quantities or magnitudes.

ASYMPTOTES, in geometry, are ſtraight lines which conſtantly approach nearer and nearer to the curve they are ſaid to be aſymptotes of: but if they and their curve are indefinitely continued, they will never meet; or aſymptotes are tangents to their curves at an infinite diſtance.

Two curves are alſo ſaid to be aſymptotical, when they continually approach to one another, but if infinitely continued, can never meet; as two parabolas that have their axes placed in the ſame right line, are aſymptotical to each other.

Of curves of the firſt order, that is, the conic ſections, only the hyperbola has aſymptotes, being two in number.

All curves of the ſecond order have at leaſt one aſymptote; but they may have three: and all curves of the fourth order may have four aſymptotes. The conchoid, ciſſoid, and logarithmic curve, have each one aſymptote. See CISSOID, CONCHOID, CURVE, HYPERBOLA, &c.

ASYMPTOTIC, ſomething relating to aſymptotes.

ASSYNDETON, in grammar, a figure which omits the conjunctions in a ſentence.

The word is Greek, and compounded of α, priv. and συνδεω, to bind together.

ATARAXY, a term uſed by the ſtoics and ſceptics to denote that calmneſs of mind which ſecures us from all emotions ariſing from vanity or ſelf-conceit. In this conſiſted the ſummum bonum, or ſovereign good.

The word is Greek, αταραξια, and compounded of α, priv. and ταραξος, perturbation.

ATAXY, in a general ſenſe, the want of order: with phyſicians it ſignifies the irregularity of criſes and paroxyſms of fevers.

The word is Greek, αταξια, and compounded of α, priv. and ταξις, order.

ATCHE, in commerce, a ſmall ſilver coin uſed in Turkey, and worth only one-third of the Engliſh penny.

ATCHIEVEMENT, in heraldry, denotes the arms of a perſon, or family, together with all the exterior ornaments of the ſhield, as helmet, mantle, creſt, ſcrolls, and motto, together with ſuch quarterings as may have been acquired by alliances, all marſhalled in order.

ATE, in the pagan theology, the goddeſs of miſchief.

She was the daughter of Jupiter, and caſt down from heaven at the birth of Hercules: for Juno having deceived Jupiter, in cauſing Euriſtheus to be born before Hercules, Jupiter expreſſed his reſentment on Ate, as the author of that miſchief, and threw her headlong from heaven to earth, ſwearing ſhe ſhould never return thither again.

The name of this goddeſs comes from αταω, noceo, to hurt. Her being the daughter of Jupiter means, that no evil happens to us, but by the permiſſion of Providence; and her baniſhment to earth denotes the terrible effects of divine juſtice among men.

ATELLANÆ, in Roman antiquity, comic and ſatyric pieces preſented on the theatre; but as in the later times they grew exceſſively lewd, they were ſuppreſſed by order of the ſenate.

A TEMPO GIUSTO, in muſic, ſignifies to ſing or play in an equal, true, and juſt time.

ATHAMADULET, the prime miniſter of the Perſian empire, as the grand vizier is of the Turkiſh empire.

The athamadulet is great chancellor of the kingdom, preſident of the council, ſuperintendant of the finances, and is charged with all foreign affairs.

ATHANASIAN CREED, that ſuppoſed to be compoſed by Athanaſius. See CREED.

ATHANATI, in Perſian antiquity, a body of cavalry, conſiſting of ten thouſand men, always complete. They were called athanati, becauſe when one of them happened to die, another was immediately appointed to ſucceed him.

ATHANOR, in chemiſtry, a kind of fixed and large digeſting furnace, made with a tower, ſo contrived as to keep a conſtant moderate heat for a conſiderable time, which may be increaſed or diminiſhed at pleaſure, by ſhutting the regiſters.

Plate IX. *fig.* 10. repreſents an athanor furnace, *a a a a*, the tower of the athanor, or chief furnace, which receives the fuel of the fire: the pricked lines indicate the thickneſs of the wall; *b b b b*, the inner ſides which form the cavity, and are each ten inches long; *c*, the door of the aſh-hole; *e*, the upper door; *d*, the grate which is placed even with the bottom of the door *e*; *f*, the cover wherewith the upper aperture of the tower is ſhut; *g g*, a flue, through which the fire aſcends from the tower into the firſt furnace; *h h h h*, a hollow priſm, which forms the firſt ſecondary furnace; *i i*, a ſemi-cylindrical arch, wherewith the aforeſaid priſm is cloſed up; *k k k k*, an iron plate coated within, wherewith the firſt ſecondary furnace is ſhut. In this plate is a round hole, through which the neck of the veſſel 7 may be paſſed; *n*, iron-bars; *o o o o*, iron-hooks, faſtened to the wall to receive the iron-bars; *q q q q*, the funnel of the furnace; *z*, an iron plate, wherewith the funnel may be ſhut; *t t*, another flue, through which the fire paſſes from the firſt ſecondary furnace to the ſecond; *u u u u*, another ſecondary furnace cylindrical; *v v*, its upper circular aperture, ſloped at the forepart, to receive an iron pot, which is to be hung in this ſecondary furnace; *z* a flue, which conveys the fire from the ſecond to the third furnace; 1 1 1 1, the third ſecondary furnace, having an iron-pot, like the ſecond; 2 2 2 2, the ſecond funnel; 3, a plate to ſhut the funnel; 4, an aperture which leads from the third furnace into the funnel; 5 5 5, the third funnel; 7, an earthen retort, placed in the firſt ſecondary furnace, with its neck through the hole in the door; 8, a receiver; 9, a glaſs retort, placed in the iron pot belonging to the ſecond ſecondary furnace, which pot is filled with ſand; 10, a receiver; 11, a glaſs cucurbit, with its head placed in the pot of the third furnace; 12, 12, ſtands which ſupport the receivers, and which may be raiſed or lowered by the help of ſcrews.

Uſes of the ATHANOR.—You muſt put in, at the upper arch-door *e*, a ſemi-cylindrical muffle, twelve inches long, of the ſame height and breadth of the door, three quarters of an inch thick, and open behind, being ſhut there by the hinder part of the athanor: for this purpoſe, a tile muſt be placed on the grate *d*, to ſupport the muffle. Under this muffle you may place your cement-pots, or ſuch bodies as muſt be calcined with a long and violent fire; which may be done without a muffle, though not ſo well. In the firſt ſecondary furnace, *h h h h*, *i i*, you may perform the moſt violent diſtillations with an open fire; for retorts and other veſſels may be introduced into it, by taking away the door *k k k*, and placed either upon the hearth itſelf, or on a particular ſupport of ſtone: but you muſt be careful to place thoſe veſſels in ſuch a manner, that their necks may paſs through the hole in the door *k k*. You may cloſe all the crevices of the door with lute. To the neck of the retort apply a cylindrical ſegment ten or twelve inches long, that the heat of the vapours may be gradually diminiſhed, leſt the receiver, which muſt be of glaſs, ſhould ſplit. The receiver muſt be luted to the other orifice of the ſaid ſegment, and ſupported by a kind of trivet. In this chamber, inſtead of diſtillations, you may make cementations, calcinations, &c. in which caſe the round hole in the iron plate *k k*, muſt be ſhut.

The ſecond and third ſecondary furnaces ſerve chiefly to perform ſuch operations as are made in baths of ſand, aſhes, or filings. You may alſo make in theſe furnaces diſtillations by a reverberating fire, as in the firſt; only the fire is leſs violent in theſe, though ſufficient for diſtilling aqua-fortis. In order to this, you muſt take out the iron pot, and invert it on the mouth of the furnace; by this means the ſegment cut out from the pot, together with that cut out from the ſide of the cavity, will form a hole for the neck of the retort.

All the apparatus being thus prepared, you muſt introduce, through the top of the tower *b b b b*, a few burning coals, and then a ſufficient quantity of fuel, ſo that the tower may be intirely filled, or only in part, according to the nature of the operation. Then immediately put on the iron cover *f*, and cloſe exactly all the crevices with lute; for if you neglect this caution, all the fuel contained in the tower would immediately be kindled, which might be attended with very bad conſequences.

Manner of regulating the fire.—The fire may be made very ſtrong in the firſt chamber *h h h h*, *i i*, by leaving the door of the aſh-hole *c*, and the funnel *q q q q*, of the chamber, quite open, and the fire have free liberty to paſs from the tower into this cavity: but the cloſer the funnel is ſhut, together with the door of the aſh-hole, the more the violence of the heat diminiſhes; and this will be ſoon effected, if the iron ſlider, which ſeparates this cavity from the tower, be partly let down. Obſerve alſo, when the ſtrongeſt fire is required, that the hole in the door *k k* be cloſely ſtopped; becauſe, when open, the air, by ruſhing violently through it, cools the bodies placed in that cavity. At the ſame time, diſtillation, or ſome other proceſs, may be performed, and with the ſame fire, in the ſecond and third furnaces; for the fire penetrates from the firſt cavity into the ſecond, and increaſes when the funnel 2 2 2 2, erected on it, is opened: but, before you do this, the funnel of the firſt cavity muſt be ſhut as much as that of the ſecond is opened. By the ſame means you may hinder the fire, which ſerves for the operations made in the two firſt cavities, from going out through their funnels, and force it out through the funnel 5 5 5, by which means it will alſo act upon the bodies placed in that cavity: for the more the funnel erected on the third cavity is open, the more one or both the funnels of the other cavities muſt be cloſed: whence it is plain, that you cannot have the ſtrongeſt fire in the third cavity, unleſs there be an equal degree of fire in the other two; but, on the contrary, the heat in the third cavity may be rendered leſs, by cloſing its funnel, though it be violent in the others. The ſame is true of the ſecond cavity, with regard to the firſt. You cannot make the ſtrongeſt fire under the muffle placed within the upper door *e*, of the tower, unleſs you have an equal fire in the firſt cavity; which fire may conſequently be increaſed by ſhutting the door quite againſt the muffle, and diminiſhed by opening it; there being, at the ſame time, an equal heat in the firſt and following chambers.

ATHEIST, a perſon, who denies the exiſtence and providence of a God, and conſequently has no religion at all, true or falſe.

The word is formed from the Greek, α, priv. and θεος, God.

There is room to doubt, whether there ever were thinking men, who have actually reaſoned themſelves into the diſbelief of a Deity. Among the ancients, indeed, we read of Theodorus of Cyrene, and Diagoras the Melian, both profeſſed atheiſts; the latter of whom ſet up a ſchool of atheiſm at Athens, for which he was proſecuted by the Athenians; but by flying out of the country, he eſcaped the puniſhment of death intended for him. About twenty years before, they had proceeded againſt Protagoras, another philoſopher, for only doubting of the being of a God. Both theſe had been the ſcholars of Democritus, the firſt founder of the atomical philoſophy, which is in its conſequences an atheiſtical ſcheme: for though it allows the being of a God in name, yet by denying his providence, it denies his exiſtence in effect. It is however probable, that theſe philoſophers were not, properly ſpeaking, atheiſts, but branded as ſuch by the pagans, for denying the divinity of their falſe gods.

Plato diſtinguiſhes three ſorts of atheiſts: ſuch as deny abſolutely that there are any gods: others who allow the exiſtence of the gods, but deny that they concern themſelves with human affairs, and ſo diſbelieve a providence: and laſtly, ſuch as believe in the gods, and a providence, but think that they are very eaſily appeaſed, and remit the greateſt crimes for the ſmalleſt ſupplication. The firſt of theſe are the only true atheiſts, in the ſtrict and proper ſenſe of the word.

Some diſtinguiſh atheiſts into ſpeculative and practical; by the former they mean ſuch as are atheiſts from principle and theory; and by the latter, thoſe whoſe lives incline them to believe, or rather wiſh to believe, there were no God.

ATHELING, ADELING, EDLING, ETHLING, or ETHELING, among our anceſtors, was a title of honour belonging to the heir apparent, or preſumptive, to the crown. This honourable appellation was firſt conferred by Edward the Confeſſor on Edgar, to whom he was great uncle, when, being without any iſſue of his own, he intended to make him his heir.

ATHENÆA, in antiquity, a feaſt celebrated by the ancient Greeks in honour of Minerva, who was called Athene.

ATHENÆUM, in antiquity, was a public ſtructure, wherein the profeſſors of the liberal arts held their aſſemblies, the rhetoricians declaimed, and the poets rehearſed their performances.

Theſe ſtructures, of which there were ſeveral at Athens, were built in the form of amphitheatres, encompaſſed with ſeats, called cunei.

ATHEROMA, in ſurgery, a tumour without pain, or diſcoloration of the ſkin, containing, in a membraneous bag, matter reſembling pap, intermixed with hard and ſtony particles. Theſe tumours are eaſily cured by inciſion.

The word is Greek, αθερωμα, and derived from αθηρα, pulp, or pap.

ATHLETÆ, in antiquity, perſons of ſtrength and agility, properly diſciplined for performing in the public games.

The word is Greek, αθλητης, and derived from αθλος, combat.

Under the name athletæ were comprehended wreſtlers, boxers, runners, leapers, throwers of the diſcus, and thoſe practiſed in other exerciſes exhibited at the Olympic, Pythian, and other ſolemn games, where prizes were eſtabliſhed for the conquerors.

ATHWART, in navigation, a-croſs; as athwart hawſe, a ſhip is ſaid to lie in that poſition when ſhe bears with her ſide againſt another's ſtem.

ATHWART *the Fore-foot*, is a ſhot generally ſo directed to ſtop a ſhip, and make her remain with her ſails ſlackened, till ſhe is examined; and is levelling the ſhot ſo that it may fall directly under the prow or ſtem.

ATHWART *Ships*, reaching from one end of the ſhip to the other.

ATLANTIDES, in aſtronomy, the ſame with Pleiades. See PLEIADES.

ATLAS, in anatomy, the name of the firſt vertebræ of the neck, or that which ſupports the head. It has its name from an alluſion to a celebrated mountain in Africa, of ſo ſtupendous a height, that it ſeems to ſupport the heavens; and from the fable, in which Atlas, king of that country, is ſaid to bear the heavens on his ſhoulders.

ATLAS, in architecture, is a name given to thoſe whole or half figures of men, ſometimes uſed inſtead of columns or pilaſters to ſupport any member in architecture. They are ſometimes called Telamones.

ATLAS, in matters of literature, denotes a book of univerſal geography, containing maps of all the known parts of the world.

ATMOSPHERE, in phyſiology, the vaſt body or collection of air that ſurrounds the earth to a very conſiderable height.

The word is formed from the Greek, ατμος, a vapour, and σφαιρα, a ſphere.

Height of the ATMOSPHERE.—The modern naturaliſts have been very ſollicitous to determine the height of the atmoſphere; a problem very difficult to be ſolved, becauſe of the elaſticity of the air, which renders its denſity different at different altitudes from the earth's ſurface: for the lower parts of the air, being preſſed by the weight of the ſuperior parts, muſt approach nearer to each other; and this approximation will be proportional to the weight of the incumbent air; whence it follows, that the denſity of the air is greateſt at the earth's ſurface, and decreaſes upwards in a geometrical progreſſion to the altitudes taken in arithmetical progreſſion.

It muſt alſo be obſerved that the rarity of the air cannot proceed *ad infinitum*, but has its limit from gravity: for though the rarefaction of the air be ſtill greater, as its diſtance from the ſurface of the earth increaſes, its ſpring at length will be ſo weakened, that the force by which the particles tend upwards from thoſe next below them, will be leſs than the force of gravity, by which they tend downwards; conſequently the rarefaction of the atmoſphere muſt be bounded where thoſe oppoſite forces are equal to each other.

Were the atmoſphere of an equal denſity throughout, the height of the atmoſphere might be eaſily determined; for it has been found, by experiment, that the length of a column of air ſeventy-two feet high, is equal in weight to a column of water of the ſame baſe, and one inch in height; conſequently the denſity of air is to that of water as 1 to 864. It has alſo been found, by experiment, that the weight of a column of air extending to the top of the atmoſphere, is equal in weight to a column of water of the ſame baſe, and 32 feet or 384 inches high. If therefore we multiply 864 by 384, we ſhall have 331776 inches, or ſomething above five miles, for the height of the atmoſphere, provided its denſity was every where the ſame.

But ſince the denſity of the atmoſphere decreaſes with the preſſure, it will be more rarefied and expanded the higher we go; and therefore the altitude of the atmoſphere becomes indefinite, terminating in pure æther. One principal effect of the air, however, being the refraction of light, whoſe particles are the ſmalleſt of any we know of in nature, it is reaſonable to fix the boundary of the atmoſphere in the altitude where it begins to have the power of producing this leaſt effect in nature, viz. the refracting a ray of light.

In order to make this plainer, let the ſun's rays coming in the direction *ſab* (Plate XVIII. *fig.* 1.) enlighten a ſegment of the atmoſphere, repreſented by the ſhaded ſegment *abga*, and terminated below by the line *ab*, touching the earth's ſurface at *d*, and above by the arch *agb*. From the end *b*, oppoſite to the ſun, draw a line *be*, touching the earth at another point *e*; and, ſuppoſing no refraction of the rays, a ſpectator at *e* might juſt perceive a faint light in his horizon *eb*, reflected to him from the air or vapours at *b*. Let the ſpectator be carried, by the earth's annual rotation, from *e* to *f*, and his horizon *be*, into the poſition *gf*, cutting *db* in *h*; and from *f* he will ſee the part *bgh* of the luminous ſegment *bgab*, by rays reflected in every poſition from every point of it. And laſtly, when the earth has carried him to *d*, the whole luminous ſegment *agba*, will become viſible to him, together with the ſun in his horizon *da*.

From this conſideration the ancient mathematicians determined the height of the atmoſphere to be about 50 miles. As ſoon as they perceived the firſt and fainteſt light on the eaſtern horizon *eb*, they obſerved the altitudes or poſitions of ſome of the brighteſt ſtars; and thence computed how many degrees the ſun was then below the horizon, and found them at a medium to be about 18. This being the meaſure of the angle *dbm*, between the two horizons *db*, *eb*, produced to *m*, or between their perpendiculars *cd*, *ce*, drawn from the earth's center, they rightly concluded, that the enlightened vapours at *b*, were ſituated in the line *cb*, which biſects the ſaid angle *dec* of 18 degrees. Now, in the right-angled triangle *cdb*, the radius *cd* is to *eb*, the ſecant of the angle *dcb* = 9 deg. as *cf* = 10000 to *cb* = 10125, or as 4000 to 4050. Since therefore, if the earth's ſemidiameter *cf*, be about 4000 miles, we have *fb* = to 50 miles, the height of the vapours at *b* above the earth's ſurface; ſuppoſing, as we before obſerved, that the horizontal rays *db*, *be*, were not refracted.

But ſince the rays AB, BA, D*c*, do each of them ſuffer a refraction inwards the curves DF, F*e*, thoſe rays will be repreſented by the dotted lines DG, *e*H, and the utmoſt height of the reflective matter I, above the earth's ſurface will be reduced to about 44 miles and an half, according to the following rule, given by Dr. Halley in the Philoſophical Tranſactions, N°. 181.—From the aforeſaid angle *dce*, of 18 deg. ſubtract twice the uſual refraction of an horizontal ray, or about one degree, and half the remainder will give the angle *dcb* = 8 deg. 30 min. and conſequently, by the ſame proportion, the height of the atmoſphere, *fb*, will be 44.4 miles; or 44 miles and a half nearly.

Preſſure of the ATMOSPHERE.—It has been already obſerved, that the weight of a column of air, extending to the boundary of the atmoſphere, is equal to the weight of a column of water of the ſame baſe, and 32 feet high; and hence the weight of any part, or of the whole atmoſphere may be determined: but this fluid is ſo ſubject to change, that it is hardly poſſible to find an equal quantity of air at different times, in the ſame place, of equal weight.

This variation is very apparent when there is any alteration in the meteors in the air: for rain, ſudden fierce ſhowers, fogs, hail, ſnow, lightning, thunder, winds, from various quarters, ſtorms, whirlwinds, drought, &c. are certain indications that the atmoſphere will ſoon become of a different weight. The different ſeaſons of the year alſo produce an almoſt incredible variation.

Hence an infinite number of effects, depending on the action of the gravity of the air, are in a perpetual viciſſitude and inconſtancy. Accurate obſervations, however, continued almoſt a century, have at laſt enabled us to determine the greateſt and leaſt gravity of the air known in Europe: for it has been found that the greateſt weight of the atmoſphere is in equilibrio with 31 inches of mercury in the barometer, while the leaſt is only equal to 27; ſo that the difference is almoſt a tenth part of its greateſt weight; and between thoſe limits the variation of the atmoſphere's weight is included. We may therefore take 29 inches for the mean altitude of the mercury, and conſequently its weight for the mean weight of a column of air of the ſame baſe. See AIR.

Hence the difference of preſſure on the body of a man, allowing it to contain 14½ ſquare feet, will be nearly equal to 3980 pounds troy. This remarkable difference muſt greatly affect the animal functions, and conſequently our health. If a perſon, for inſtance, be aſthmatical, he will find his diſorder increaſe with the levity of the air; for ſince a pure, denſe, elaſtic air is alone capable of diſtending his lungs in reſpiration, it will be leſs capable of performing the ſame office, when its weight and elaſticity are decreaſed; and conſequently the valetudinarian will find his difficulty of breathing increaſe in proportion.

It is common to conſider the air as heavieſt in foggy weather: but the contrary is true; for the air is actually heavieſt in fine clear weather. The reaſon for this error flows from our miſtaking the cauſe. When the fibres and nerves are braced and conſtringed by the great preſſure of the air, the blood veſſels act with their full power and natural vigour, a proper velocity is given to the fluids, and a greater momentum to overcome obſtructions in the capillaries. Hence we find ourſelves alert and light, and thence fancy that the air is light alſo.

On the contrary, when this preſſure is leſſened by near 3980 pounds, the fibres are relaxed, the contractile force of the veſſels diminiſhed, a languid circulation enſues, obſtructions, &c. happen, and produce agues, fevers, aches, &c. in ſome; and in all, a ſort of indolence, or gloomy inactivity, and heavineſs; conſequences which we imagine reſult from the heavineſs of the air; whereas they, in reality, flow from its levity.

Refractive Power of the ATMOSPHERE.—Beſides other innumerable conveniences we receive from the atmoſphere, it is a principal cauſe of rendering our earth that beautiful ſcene it now appears. It is the atmoſphere that makes the face of the heaven or firmament appear lucid and bright while the ſun ſhines; for if no atmoſphere ſurrounded and involved the earth, only that part of the heavens in which the ſun was placed, would appear to ſhine; and a ſpectator, if he ſhould turn his back to the ſun, would immediately perceive it as dark as night; and even in the day-time, while the ſun ſhined, the leaſt ſtars would be ſeen as plainly as in the darkeſt night, becauſe there would be no ſubſtance to reflect the ſun's rays to our eyes; and all the rays that do not fall upon the ſurface of the earth paſſing by us, would either illuminate the planets and ſtars, or ſpreading themſelves out in infinite ſpace, would never be reflected back to us.

But ſince there is an atmoſphere ſurrounding the earth, which is ſtrongly illuminated by the ſun, it reflects the light back to us, and cauſes the whole heavens to ſhine with ſuch ſplendor, as to obſcure the faint light of the ſtars, and render them inviſible.

If there were no atmoſphere, the ſun would ſhine as bright as at noon juſt before his ſetting, and the moment he was below the horizon, the whole face of the earth would be involved in as pitchy darkneſs as at midnight. The ſame phænomena would alſo attend the ſun's riſing. But how inconvenient muſt ſuch ſudden tranſitions from the greateſt darkneſs to the greateſt light prove to the inhabitants of the earth? This inconvenience is removed by the atmoſphere; for though after ſun-ſetting we receive no direct light from the ſun, yet we enjoy his reflected light for a conſiderable time; ſo that the darkneſs of the night comes on gradually. In the morning alſo, as ſoon as the ſun comes within 17 deg. 30 min. of the horizon, he begins again to enlighten the atmoſphere, and to diffuſe his light through the heavens; its brightneſs continuing to encreaſe by degrees, till the ſun riſes, and makes full day.

ATMOSPHERE *of the Moon.*—Sir Iſaac Newton mentions an atmoſphere of the moon, while others are perſuaded there is no ſuch thing, becauſe it cannot be perceived. But if we ſuppoſe the moon's denſity to be the ſame with that of the earth, and to have an equal proportion of fluids, the height of the atmoſphere, ſuppoſing that planet to have one, would be ſo ſmall, that it could not be perceived by the niceſt obſerver. It will be allowed that the height of the atmoſphere will be in proportion to the velocity of the moon round its axis, and the quantity of fluids on its ſurface. The velocity of the moon round its axis is leſs than the twenty-ſeventh part of the velocity of the earth round its axis; and the quantity of fluids on the ſurface of the moon will be leſs than the twelfth part of the quantity of fluids on the ſurface of the earth; conſequently the height of the atmoſphere of the moon muſt be very little in compariſon of the height of the atmoſphere of the earth. Suppoſing the atmoſphere of the earth to be fifty miles, which is much too great, the height of the atmoſphere of the moon would be leſs than the ſixth part of a mile; which, if viewed from the earth, would ſubtend an angle leſs than the ſixth part of a ſecond.

The reaſon aſſigned by ſome aſtronomers for alledging that the moon has no atmoſphere is, that if the moon had an atmoſphere, the planets and ſtars which are often ſeen near its limb, (and ſometimes the moon paſſes over them) would have their light refracted. But it ſhould be obſerved that, during the tranſit of the moon over a planet or fixed ſtar, the time of the tranſit of the atmoſphere of the moon would be leſs than the third part of a ſecond of time; which time is ſo ſmall, that no aſtronomer can pretend to obſerve it. See STEWART's *Diſtance of the Sun from the Earth determined*, &c.

ATMOSPHERE *of the Sun.* See SUN.

ATMOSPHERE *of Solid*, or *conſiſtent Bodies*, a kind of ſphere formed by the minute corpuſcles, or effluvia, emitted from them.

ATOM, in philoſophy, an indiviſible particle, or corpuſcle of matter.

The word is Greek, *ατομος*, and compounded of *α*, priv. and *τεμνω*, to cut or divide.

Atoms are properly the *minima naturæ*, the leaſt or ultimate particles into which bodies are diviſible; and are conceived to be the firſt rudiments, or component parts of all phyſical magnitude; or the pre-exiſtent and incorruptible matter whereof bodies are formed.

The notion of atoms ariſes from a ſuppoſition, that matter is not diviſible *ad infinitum.* And hence the Peripatetics are led to deny the reality of atoms: An atom, ſay they, either has parts, or it has not: if it has no parts, it is a mere mathematical point; if it has, theſe parts muſt alſo conſiſt of others, and ſo on to infinity.

But this is to recede from the genuine characters of atoms, which are not eſteemed indiviſible from their want of parts (for all phyſical magnitude muſt have three dimenſions, length, breadth, and thickneſs; and all extenſion is diviſible); but they are indiviſible on account of their ſolidity, hardneſs, and impenetrability, which preclude all diviſion, and leave no vacancy for the admiſſion of any foreign force to ſeparate or diſunite them.

It is neceſſary that atoms, as being the firſt matter, ſhould be indiſſolvible, in order to their being incorruptible. Sir Iſaac Newton adds, that immutability is alſo requiſite, in order to the world's continuing in the ſame ſtate, and bodies being of the ſame nature now as formerly.

Hence the ancients were alſo led to maintain that atoms were eternal; for what is immutable muſt be eternal.

ATOMICAL *Philoſophy*, the doctrine of atoms; or the method of accounting for the origin and formation of things from the ſuppoſition of atoms being endued with gravity and motion. See CORPUSCULAR *Philoſophy.*

ATONY, in phyſic, a relaxation, or debility of the ſolids of the human body.

The word is Greek, *ατονια*, and compounded of *α*, priv. and *τονος*, tone.

The methodic ſect conſidered relaxation and ſtricture, or a mixture of theſe, as the cauſes of all diſtempers.

ATRA BILIS, black bile, among the ancient phyſicians, implied one of the humours of the body; the moderns call it melancholy. See MELANCHOLY.

A-TRIP, in navigation, a ſhip's top-ſails are ſaid to be a-trip when they are hoiſted up to their full extent, or to the maſt-head.

A-TRIP, the anchor is ſo called, when the ſhip, in a perpendicular direction, drags or heaves it out of the ground.

ATROPHY, in phyſic, implies an univerſal conſumption, proceeding from the whole habit of body, and not from any diſtemper of the entrails; it is attended with no remarkable fever, and is natural in old age.

The word is Greek, *ατροφια*, and compounded of *α*, priv. and *τρεφω*, to nouriſh.

An atrophy is either nervous, or the effect of immoderate evacuations. A nervous atrophy is that which owes its origin to a bad and morbid ſtate of the ſpirits, or to a weakneſs or deſtruction of the tone of the nerves: whence a weakneſs and an univerſal conſumption of the body proceeds, for want of a proper aſſimilation of the nutritious juices; ſo that, from the beginning of the diſeaſe, there is a defect of appetite, and a bad digeſtion in the ſtomach.

An atrophy from inanition proceeds from a preternatural defect or ſubtraction of the nutritious juice, which varies according to the different outlets of the body, whether by nature or art. See CONSUMPTION.

ATTACHMENT, in law, implies the taking or apprehending a perſon, by virtue of a writ or precept.

It is diſtinguiſhed from an arreſt, by proceeding out of a higher court by precept or writ; whereas the latter proceeds out of an inferior court by precept only. An arreſt lies only on the body of a man; whereas an attachment lies often on the goods only, and ſometimes on the body and goods.

An attachment by writ differs from diſtreſs, in not extending to lands, as the latter does; nor does a diſtreſs touch the body, as an attachment does.

In the common acceptation, an attachment implies the apprehenſion of a man's body, in order to his anſwering the action of the plaintiff.

ATTACHMENT *out of the Chancery* is obtained upon an affidavit made, that the defendant was ſerved with a ſubpœna, and made no appearance; or it iſſueth upon not performing ſome order or decree. Upon the return of this attachment by the ſheriff, *quod non eſt inventus in balliva ſua*, another attachment, with a proclamation, iſſues; and if he ſtill refuſes to appear, a commiſſion of rebellion.

ATTACHMENT *of the Foreſt* is one of the three courts held in the foreſt.

The loweſt court is called the court of attachment, or wood-mote court; the mean, ſwan-mote; and the higheſt the juſtice in eyre's ſeat.

The court of attachments has its name from the verdurers of the foreſt having no other authority in it, but to receive the attachments of offenders againſt vert and veniſon taken by the foreſters, and to enroll them, that they may be preſented or puniſhed at the next juſtice in eyre's ſeat.

This attachment is by three means; by goods and chattels, by body, pledges, or mainprize; or by the body only. This court is held every forty-days throughout the year; and is thence called forty-days court.

ATTACHMENT *of Privilege*, is by virtue of a man's privilege to call another to that court whereto he himſelf belongs, and in reſpect whereof he is privileged to anſwer ſome action.

Foreign ATTACHMENT is an attachment of money or goods found within a liberty or city, to ſatisfy ſome creditor within ſuch liberty or city.

By the cuſtom of London, and ſeveral other places, a man can attach money or goods in the hands of a ſtranger, to ſatisfy himſelf.

Attachiamenta *Bonorum*, in our old ſtatute books, imports a diſtreſs taken upon the goods, or chattels of a perſon ſued for a perſonal eſtate, or debt, by the legal attachiators, or bailiffs, as a ſecurity to anſwer the action.

Attachiamenta *de Spinis & Boſco*, denotes an ancient privilege granted to the officers of foreſts, to take to their own uſe thorns, bruſh, and windfalls within their own precincts or liberties.

ATTACK, a violent attempt upon any perſon or thing, an aſſault, or the act of beginning a combat, or diſpute.

Attack, in the military art, is an effort made to force a poſt, break a body of troops, &c.

Attack *of a Siege*, is a furious aſſault made by the beſiegers with trenches, covers, mines, &c. in order to make themſelves maſters of a fortreſs, by ſtorming one of its ſides. If there are two or three attacks made at the ſame time, there ſhould be a communication betwixt them.

Plate V. *fig.* 2. repreſents an attack of a regular fortification, ſituated in a level country; A, B, baſtions in the front of the attack; C, a half moon in the ſame front; D, D, prolongations of the capitals of A and B; E, a prolongation of the capital of the half moon; F, F, piquets for marking out the lines of prolongation from the capitals, in order to conduct the trenches; G, G, batteries for firing in ricochet againſt the two faces and the covert way of the half moon C; H, a ricochet battery againſt the left face and covert-way of the baſtion A; I, a ricochet battery againſt the right face and covert-way of the baſtion B; K, ricochet batteries againſt the two other faces and covert-way of the baſtions A and B; L, L, ricochet batteries againſt the faces and covert-way of the two collateral half moons M, N; O, O, bomb batteries; P, P, places on the ſecond line for other batteries when neceſſary; R, R, cavaliers of the trenches, which enfilade the covert-way; R, R, ſtands of arms; S, S, picquets on the lines of prolongation from the attacking batteries for placing the pieces in ricochet; T, T, paſſages through the firſt parallel formed of faſcines for carrying cannon to the batteries; V, V, redoubts which terminate the ſecond parallel Y, Y; X, X, firſt parallel, or place of arms; Z, Z, third parallel, or place of arms; *a*, *a*, way of communication between attacks.

Plate VIII. *fig.* 1. repreſents the batteries and lodgments on the covert-way; A, B, baſtions in front of the attack; C, a half moon in the ſame front; *a*, *a*, demi-places of arms; *b*, *b*, cavaliers of the trenches; *c*, *c*, batteries of padereros; *d*, *d*, batteries in breach of the half moon C; *e*, *e*, batteries againſt the faces of the baſtions A and B, which defend the half moon: *f*, *f*, paſſages through the ditch to the half moon; *g*, *g*, lodgments in that work; *h*, *h*, batteries in breach of the baſtions A and B; *i*, *i*, batteries againſt the defences of the baſtions; *k*, *k*, batteries againſt the courtin and the faces of the baſtions; *l*, *l*, paſſages through the ditch to the baſtions; *m*, *m*, lodgments there; *n*, *n*, third parallel or place of arms.

The other figures on the plate repreſent the manner of paſſing the ditch when it is either dry or full of water.

Fig. A is a profil of a deſcent into the ditch by means of a ſort of gallery *a*, formed under the covert-way, and which extends from the counterſcarp *b*, on a level with the bottom of the ditch, to the breach *d*; *m*, the lodgment on the covert-way.

Fig. B, a view of the deſcent from the ſide of the country; *a*, entrance of the gallery; *m*, lodgment on the covert-way; *d*, the breach.

Fig. C. Profil of a deſcent into the ditch when full of water; *f*, *g*, a gallery level with the water, and covered with blinds and faſcines; *n*, the epaulement and bridge made in the ditch for gaining the foot of the breach *b*.

Fig. D, view of the ſame deſcent from the ſide of the country; *f*, the opening at the beginning of the gallery; *m*, lodgment in the covert-way; *b*, the breach.

Falſe **Attack**, an attack made with a deſign to favour the true attack, by amuſing the enemy, and obliging him to divide his forces.

ATTAINDER, in law, is when a man has committed felony or treaſon, and ſentence is paſſed upon him for the ſame. The children of a perſon attainted of treaſon, are thereby rendered incapable of being heirs to him, or to any other anceſtor; and if he were noble before, his poſterity are degraded and made baſe: nor can this corruption of blood be ſalved, but by an act of parliament, unleſs the ſentence be reverſed by a writ of error.

Attainder is two-fold, either by appearance, or by proceſs.

Attainder by appearance, is either by battle, by confeſſion, or by verdict. By battle, is when the party appealed by another, chooſing rather to try the truth by combat than by jury, is vanquiſhed. Attainder by confeſſion, is either by pleading guilty at the bar, and not putting himſelf upon trial by the jury, or before the coroner in ſanctuary, where, in ancient times, he was obliged to renounce the realm.

Attainder by verdict, is when the priſoner at the bar pleads not guilty to the indictment, and is pronounced guilty by the jury.

Attainder by proceſs, otherwiſe called attainder by default, is where a party flies, or does not appear after being three times publicly called in the county court, and at laſt, upon his default, is pronounced guilty.

Bill of **Attainder**, a bill brought into parliament for attainting, condemning, and executing a perſon for high treaſon.

ATTAINT, in law, a writ which lies againſt a jury that have given a falſe verdict in any court of record, in a real or perſonal action, where the debt or damages amount to above forty ſhillings.

If the verdict be found falſe, the judgment, by common law, was, that the jurors meadows ſhould be ploughed up, their houſes broken down, their woods grubbed up, all their lands and tenements forfeited, &c. but by ſtatute the ſeverity of the common law is mitigated, where a petty jury is attainted, and there is a pecuniary penalty appointed.

But if the verdict be affirmed; ſuch plaintiff ſhall be impriſoned and fined.

Attaint, among ferriers, a knock or hurt in a horſe's leg, proceeding either from a blow with another horſe's foot, or from an over-reach in froſty weather, when a horſe being rough ſhod, or having ſhoes with long calkers, ſtrikes his hinder feet againſt his fore-legs.

ATTAINTED, in law, is applied to a perſon found guilty of any crime or offence, eſpecially of treaſon or felony, by due courſe of law.

ATTENTION, the applying either the ear or the mind aſſiduouſly to any thing ſaid or done, in order to underſtand it.

The word is Latin, *attentio*, and compounded of *ad*, to, and *tendo*, to ſtretch, or bend.

To increaſe attention, we muſt baniſh every thing that may interrupt it, and ſeek every means to ſtrengthen and aſſiſt it. Our ſenſes are apt to divert our attention; new ſenſations obſcure, efface, and obliterate acts of imagination. Yeſterday you ſaw a fine piece of painting, were ſo ſtruck with it, that its idea quite poſſeſſed you; another, offered to your view to-day, drives the former out of your imagination; thus external objects deſtroy attention: for this reaſon ſome pray with their eyes ſhut, or directed ſteadily towards ſome fixed and immoveable point. Students chooſe a room remote from noiſe and the interruption of external objects; and the ſtudies of the night have been more ſucceſsful than thoſe of the day, becauſe a more univerſal calm and ſilence reigns.

The hurry of the imagination deſtroys attention as much as that of our ſenſes; after a play, it is difficult to reſume our ſtudies immediately; next day ſome images will recur, apt to divert us, and interrupt our attention. The ſenſes, the imagination, and the paſſions operate upon the ſoul, and give it a kind of modification. All, therefore, who would apply themſelves ſtrenuouſly to the diſcovery of truth, ſhould be careful to avoid ſtrong and immoderate ſenſations, a great noiſe, a glaring light, exceſs of grief, or joy, &c. they ought to keep their imagination free from any thing that weakens or diſquiets the mind. They ought, eſpecially, to control their paſſions, which, let looſe, make very powerful impreſſions on the ſoul and body, and exerciſe a ſtrange dominion over both;

yet the paſſions and the ſenſes may be made of uſe to preſerve our attention: as, for inſtance, a deſire of diſcovering truth, rendering ourſelves uſeful to our neighbours, and improving ourſelves, is highly laudable, and tends to fix our attention: but our attention is fixed alſo by motives much leſs generous and noble, a thirſt of fame, deſire of riches, nay, even vanity. Experience ſhews us the ſenſes are of no ſmall ſervice to fix the attention; for they have a natural connection with our ſituation; a man, retired to meditate in a ſolitary cell, will be alarmed, diſtracted, and his attention entirely deſtroyed by an unexpected noiſe, or intermiſſion of adventitious light; ſo, if we, on the contrary, reflect ſtrongly on an object amidſt day-light and noiſe, that idea baniſhes all others and poſſeſſes us; thus light and noiſe are no interruptions to attention, but ſerve to fix it more ſtrongly. It is, in ſhort, a habit of the mind: and the philoſophers, who have ſhut their eyes to help their meditation, have furniſhed us with nothing but chimeras. Had Deſcartes kept his eyes open to have ſurveyed the univerſe with attention, inſtead of ſinking into meditation, he would never have publiſhed ſuch dreams as he has for a plan of the univerſe. Attention is progreſſive, and the power of it may be acquired, but depends, in ſome meaſure, on the conſtitution.

ATTENUANTS, in pharmacy, are medicines which reſolve the viſcocity of the humours in the human body, and thereby promote their free circulation, and, at the ſame time, diſcharge all noxious and excrementitious matter.

The word is formed from the Latin, *ad*, and *tenuo*, to render ſmall.

ATTESTATION, the act of affirming, or witneſſing, the truth of ſomething, eſpecially in writing.

The word is Latin, *atteſtatio*, and compounded of *ad*, to, and *teſtis*, a witneſs.

ATTIC, ſomething relating to Attica, or the city of Athens. Thus, attic ſalt, *ſales attica*, implies a delicate and poignant ſpecies of wit and humour peculiar to the Athenian writers: attic witneſs, *atticus teſtis*, a witneſs incapable of corruption, &c.

ATTIC, in architecture, a ſort of building; the roof or covering of which is concealed; ſo called from the Athenian buildings, which were in general of this form.

ATTIC *Order*, in architecture, a ſmall order raiſed upon a large one, by way of crowning, or to finiſh the building.

The word is alſo applied to the whole ſtory, into which this order enters.

ATTIC *of a Roof*, a kind of parapet to a terras, platform, or the like.

ATTIC *Continued*, that which encompaſſes the whole circumference of a building, without any interruption, following all the jetts, the returns of the pavilions, &c.

ATTIC *Interpoſed*, one ſituated between two tall ſtones, ſometimes adorned with columns, or pilaſters.

ATTIC *Baſe*. See the article BASE.

ATTIRE, in botany, a name given by ſome to the generative parts of plants; and by others, to imply the third part or diviſion of the flower of a plant; the other two being the empalement and the foliation, or the cup and the flower petals.

ATTIRE, in hunting, ſignifies the head or horns of a deer. See the article HEAD.

ATTITUDE, in painting and ſculpture, ſignifies the geſture of a figure or ſtatue; or ſuch a diſpoſition of their parts as ſerves to expreſs the action and ſentiments of the perſon repreſented.

The word is formed from the Italian, *attitudine*, which ſignifies the ſame thing.

ATTOLENS, in anatomy; ſee LEVATORES and ELEVATORES.

The word is compounded of the Latin, *ad*, to, and *tollo*, to raiſe.

ATTORNEY, in a general ſenſe, a perſon appointed by another to do ſometing in his ſtead.

The word is formed from the Latin, *ad*, to, and the French, *tourner*, to turn; q. d. to turn a buſineſs over to another.

ATTORNEY *at Law*, one who is retained to proſecute or defend a law-ſuit.

Attornies, being properly thoſe who ſue out writs, or proceſs, or commerce, carry on, and defend actions, in any of the courts of common law, are diſtinguiſhed from ſolicitors, as the latter do the like buſineſs in the courts of equity; and none are admitted, either as an attorney or ſolicitor, unleſs they have ſerved a clerkſhip of five years, been enrolled, and taken the oath in that caſe provided; and the judges of their reſpective courts are required to examine their ſeveral capacities.

By a late order of all the judges, all attornies are to be admitted of ſome inns of court or chancery (except houſe-keepers in London and Weſtminſter, &c.) and no attorney ſhall put himſelf out of that ſociety, into which he is admitted, till he is admitted to ſome other ſociety, and deliver a certificate thereof; and all attornies are to be in common at the times ordered by the ſociety to which they belong, otherwiſe ſhall be put out of the roll of attornies.

Attornies may be puniſhed for ill practices; and if an attorney, or his clerks, of which he muſt have but two at one time, do any thing againſt the expreſs rules of the court, he or they may be committed.

Neither a plaintiff nor defendant may change his attorney without rule of court, while the ſuit is depending; and attornies are not generally obliged to deliver up the writings in their hands, till their fees are ſatisfied: likewiſe, an action does not lie againſt an attorney, for what he adviſes in the way of his profeſſion; yet, if an attorney plead any plea, or appear, without warrant from his client, action of the caſe lies againſt him.

Attornies have the privilege to ſue and be ſued only in the courts of Weſtminſter, where they practiſe; and they ſhall not be choſen into offices againſt their will.

ATTORNEY *of the Dutchy of Lancaſter* is the ſecond officer in that court, and ſeems to be there, for his ſkill in the law, placed as aſſeſſor to the chancellor of the court.

ATTORNEY-GENERAL is a great officer under the king, created by letters patent, whoſe office is to exhibit informations, and proſecute for the crown in criminal cauſes; and to file the bills in the exchequer, for any thing concerning the king in inheritance or profits. To him come warrants for making of grants, pardons, &c. his ſalary from the crown is 1000l. per ann.

ATTORNMENT, in law, implies a transfer made from one lord to another, of the homage and ſervice a tenant makes; or that acknowledgment of duty to a new lord.

ATTRACTION, in natural philoſophy, an indefinite term applicable to all actions whereby bodies tend towards one another, whether by virtue of their weight, electricity, magnetiſm, impulſe, or any other latent power.

The word is Latin, *attractio*, and compounded of *ad*, to, and *traho*, to draw.

Philoſophers generally reckon four different ſorts of attraction, viz. that of coheſion, of electricity, of magnetiſm, and gravitation.

ATTRACTION *of Coheſion*, is peculiar to the component particles of bodies, by virtue of which they are firmly connected and held together. The laws and properties of this attraction are the following: 1. It is very diſcernable and moſt powerful in corpuſcles, or the ſmalleſt particles of matter. 2. It is mutually exerted between thoſe particles; or they mutually attract, and are attracted by each other. 3. The ſphere of attraction, or extent of this power, is greater in ſome particles of matter than in others, but very ſmall at the outermoſt: for, 4. this power is inſenſible in ſolid bodies in the leaſt ſenſible diſtance, acting as it were only in contact; and, therefore, 5. it muſt be nearly proportional to the quantity of contiguous ſurfaces; or the parts of the body cohere moſtly ſtrong, whoſe touching ſurfaces are largeſt. 6. This power muſt decreaſe, as the ſquares of the diſtances increaſe; becauſe it muſt be ſuppoſed to iſſue from each particle in right-lined directions. 7. Where the ſphere of attraction ends, there a repelling power begins; by which the particles, inſtead of attracting, repel and fly from each other. 8. By this power, the ſmall portions or drops of a fluid, conform themſelves to a ſpherical figure.

The firſt and ſecond of theſe properties, are evident from

PLATE IX. Facing Attraction.

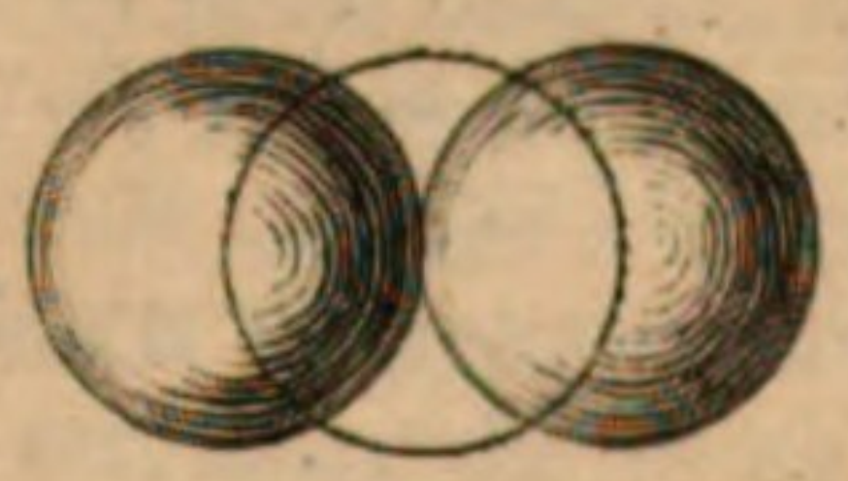
Athanor.

Fig. 10.

Fig. 11. Attraction.



from various experiments; as the ſudden union of two contiguous drops of mercury, water, &c. Thus the drops, plate IX. *fig.* 11. will, as ſoon as they touch each other, run together, and form one large drop. The ſtrong adheſion of two leaden balls, which touch by poliſhed ſurfaces; as alſo of glaſs panes, and in capillary tubes; the riſing of water by the ſides of a glaſs veſſel, and into tubes of ſand, aſhes, ſugar, ſponge, and all porous ſuſtances.

The third property is proved by the ſticking or adhering of water to ſubſtances, which by mercury are left dry: The fourth and fifth properties are evinced by the hyperbolic curve, formed by the ſuperficies of a fluid aſcending between glaſs-panes touching each other on one ſide. The ſixth property is evident. The ſeventh appears from the aſcent of a ſteam, or vapour, from humid or fluid bodies; and the eighth property is manifeſt by drops of water falling on duſt.

From this account of the attraction of coheſion, we have a rational ſolution of ſeveral very curious and ſurpriſing phænomena; as why the parts of bodies adhere and ſtick ſo firmly together; why ſome are hard, others ſoft; ſome fixed, others fluid; ſome elaſtic, others void of elaſticity: all which ariſe from the different figures of the particles, and the greater or leſſer degree of attraction conſequent thereupon. On this principle, we account for the manner how plants imbibe the nutritive juices by the fibres of the roots; alſo for the riſe of the ſap in vegetables, and for the whole œconomy of vegetation. Hence the rationale of the various ſecretions of fluids by the glands, and their wonderful circulation through the fine capillary veſſels. Hence alſo the reaſon of ſoldering and gilding metals; alſo of melting, or fuſion, by heat. Hence alſo the exhalation of vapour by the heat of the ſun or fire; the aggregation of aqueous particles in the air, forming the drops of rain. We hence ſee the reaſon of diſtillation, filtration, diſſolution, digeſtion, ſublimation, precipitation, cryſtallization, and the other operations of chemiſtry and pharmacy. Laſtly, it is by this power of attraction and repulſion, that we are to account for thoſe wonderful phænomena of ſubterranean aſcenſions and exploſions; of volcanos and earthquakes; of hot ſprings, damps, and ſuffocating exhalations in mines, &c. See the article COHESION.

The ſecond ſpecies of attraction is that of electrical bodies, as glaſs, amber, ſealing-wax, jet, &c. for the properties of which, ſee ELECTRICITY.

For the properties of the third kind of attraction, ſee the articles MAGNET and MAGNETISM.

The fourth kind of attraction, viz. that of gravitation, though reckoned a diſtinct ſpecies from that of coheſion; yet, when well conſidered, may be found perhaps to differ from it no otherwiſe than as a whole from the parts: for the gravity of large bodies may be only the reſult or aggregate of the particular powers of the conſtituent particles, which ſingly act only in contact, and in ſmall diſtances; but with their joint forces, in vaſt quantities, produce a mighty power, whoſe efficacy extends to very great diſtances, proportional to the magnitudes of the bodies.

This attractive force of gravity is, to ſenſe, the ſame for any diſtance near the ſurface of the earth; becauſe ſuch diſtances do not ſenſibly alter the diſtance from the center of the earth: but when the diſtance is ſo great as to bear a conſiderable proportion to the ſemi-diameter of the earth; then will the power of gravity decreaſe very ſenſibly. Thus, at the diſtance of the moon, which is, at a medium, about ſixty ſemi-diameters of the earth, the power of gravity will be to that on the earth's ſurface, as 1 to 3600, as will be ſhewn under the article of CENTRAL FORCES. See alſo the articles GRAVITY and GRAVITATION.

All philoſophers agree that there is a certain force by which the primary planets tend towards the ſun and the ſcondary planets towards their primary. As we ought carefully to avoid multiplying principles, and impulſe is the moſt known and leaſt controverted principle of the motion of bodies, it is clear, a philoſopher would naturally attribute this impelling power to a fluid. To this notion, the vortices of Des Cartes owe their birth, and this opinion ſeemed more plauſible, becauſe it accounted for the motions of the planets by the circular motion of the matter of the vortices, and their tendency towards the ſun by the centrifugal force of the ſame matter: but an hypotheſis is not to be admitted, which accounts only for gegeral phænomena; particular phænomena are the teſts of an hypotheſis, and the failure of the Carteſian ſyſtem in theſe overturned it. The doctrine of vortices is therefore juſtly exploded, as ſo many difficulties attend it which never can be ſurmounted; for, if the planets move by virtue of the action of a fluid, this fluid muſt have contrary properties, it muſt impel in one intention, and in another make no reſiſtance, an apparent abſurdity; and the remedy is worſe than the diſeaſe; for the force by which the planets tend towards the ſun, muſt, on this hypotheſis, be aſcribed to an occult quality, which is ſaying nothing at all: and Ariſtotle, who perhaps invented the term, is much more pardonable than many modern philoſophers who have blindly followed him.

We may therefore truly aſſert, that attraction is a primordial quality of matter; nor is it perhaps poſſible to explain the celeſtial bodies on the principle of impulſion. Sir Iſaac Newton ſeems to waver in ſome parts of his works concerning the nature of attraction, and admits of an impelling power; there is reaſon to think it was a kind of tribute he choſe to pay to the prejudice, or rather the general opinion of the age he lived in, than his real ſentiment; becauſe he permitted Mr. Cotes, his diſciple, to adopt attraction without reſerve, as may be ſeen in the preface to his ſecond edition of his Principia; and this preface was written under the eye of Sir Iſaac, and had his approbation. Beſides, Sir Iſaac admits a reciprocal attraction among the celeſtical bodies, and this very opinion ſeems to ſuppoſe attraction a quality inherent in bodies; but be that as it may, according to Newton, the attractive force decreaſes in an inverſe ratio to the ſquares of the diſtances: this learned philoſopher has ſolved a great part of the celeſtial phænomena on this ſingle principle, and all who have tried to account for them ſince, on the ſame principle, have ſucceeded to a ſurpriſing degree of exactneſs. The motion of the moon's apogee, which was pretended to be irreconcileable to this hypotheſis, is now found to be entirely conformable to it, and does honour to the Newtonian ſyſtem. All the other inequalities of the motion of the moon, which are very conſiderable, may alſo eaſily be accounted for by the ſyſtem of attraction, and demonſtrated by calculation.

All the phænomena hitherto obſerved, demonſtrate a mutual tendency of the planets towards each other; wherefore we muſt admit this for a truth on its own evidence; and, though we ſhould be forced to acknowledge this a primordial and inherent quality in matter, we may venture to ſay, that the difficulty of conceiving ſuch a cauſe would be a very weak argument againſt its exiſtence. No one doubts but that a body which meets another, communicates motion to it; but have we an idea of the power by which this communication is made? The vulgar eye here, perhaps, penetrates as far as that of the philoſopher. No body is ſurpriſed at ſeeing a ſtone fall; they have always ſeen it; philoſophers, well acquainted with the effects of impulſion, have never troubled themſelves about the cauſe which produces them. Now, if every body which meets another ſhould ſtop without communicating motion to it, a philoſopher would be as much aſtoniſhed at this phænomena, as a common man at ſeeing a heavy body ſuſpended in the air. If we underſtood wherein the impenetrability of matter conſiſts, we ſhould not perhaps be clearer about the nature of the impelling power. We only ſee that, in conſequence of this impenetrability, the ſhock of one body againſt another muſt be followed by ſome change, either in both or one of the bodies; but we know not, and perhaps never ſhall, by what power this change is effected; and why, for inſtance, a body which ſtrikes againſt another ſhould not always continue at reſt after the ſhock, without communicating a part of its motion to the body which reſiſts it. It is apprehended attraction contradicts the notion we have of matter; but, if we enquire attentively, we ſhall find theſe ideas no ways repugnant. The univerſe is concealed from us by a curtain, we ſee only ſome part of it; were that drawn up on a ſudden, we ſhould be ſurprized to ſee what paſſes behind it: beſides, the pretended inconſiſtence of attraction, with the nature of matter, is ſolved by admitting an intelligent being, who could as eaſily ordain bodies to act on each other at a diſtance, as in contact.

M. de Maupertuis, in his diſcourſe on the figures of the planets, has given an idea of the ſyſtem of attraction, with remarks on it: and the ſame author obſerves, in the Mem. Acad. 1734, that, long before Sir Iſaac Newton, Roberval de Fermat and Paſcal thought gravity an attractive power, and inherent in bodies. We will add, that Hook had the ſame notion, and foretold that all the motions of the planets would one day be accounted for on this ſingle principle. Theſe reflections, by increaſing the number of great men, who were of the ſame opinion with Sir Iſaac, take nothing from his glory; for, as he was the firſt who actually demonſtrated this principle, he is properly the author of it.

ATTRACTION *of Mountains.* If it be admitted that all parts of the earth attract each other mutually, it muſt be granted that there are mountains on it, whoſe magnitude is conſiderable enough to make a ſenſible attraction. Let us ſuppoſe the earth a globe of an uniform figure, whoſe radius is equal to 1500 leagues, and ſuppoſe a mountain on the ſurface of ſome part of this globe one league in height, it is eaſy to demonſtrate, that a weight placed at the bottom of this mountain ſhall be attracted horizontally by the mountain, with a force equal to a 3000th part of the weight; ſo that a pendulum or plumb-line, placed at the bottom of this mountain, muſt deviate from a perpendicular about a minute; the calculation is not difficult, and this may be admitted by way of ſuppoſition: from whence it follows, that when we obſerve the elevation of a ſtar at the foot of a great mountain; the plumb-line muſt deviate from a perpendicular; and an obſervation of this kind, certainly, would afford a very ſtrong proof in favour of the ſyſtem of attraction: but, it may be objected, how ſhall we be ſure the plumb-line actually deviates from a perpendicular, as the direction of the plumb-line only determines the vertical ſituation of the ſtar? This difficulty is eaſily ſurmounted.

Let us ſuppoſe a ſtar on the north of the mountain, and the perſon who is to make his obſervation placed on the ſouth: if the attraction of the mountain acts ſenſibly on the plumb-line, it will deviate from a perpendicular towards the north; and, conſequently, the apparent zenith of the ſtar will go back towards the ſouth; and ſo the diſtance of the ſtar, on which the obſervation is made in the zenith, muſt be greater than if there was no attraction.

After having made this obſervation, if we go at a diſtance from the mountain, on a right line towards the eaſt or weſt, ſo far that the attraction no longer operates, an obſervation, made in this new ſtation, will ſhew the ſtar at a leſs diſtance than in the former.

But there is another and better method. It is certain, that, if the plumb-line on the ſouth-ſide of the mountain deviates towards the north, the plumb-line in the north ſide muſt deviate towards the ſouth, and the zenith of the ſtar, which in the firſt caſe went back towards the north, muſt, in the latter, advance towards the ſouth: therefore, taking the difference of theſe two diſtances, and dividing it into two equal parts, will ſhew how much the pendulum has deviated from a perpendicular by the attraction of the mountain.

The whole theory is clearly explained, with ſeveral remarks, in an excellent Memoir of M. Bouguer's, printed in the year 1749, at the end of his book on the figure of the earth: in which he gives an account of the obſervations he made in company with M. Condamine, on the north and ſouth ſides of the great mountain Chimboraco, in Peru; the reſult of his obſervations is, that the attraction of this great mountain cauſes a deviation of the plumb-line from its perpendicular of $7''$ and a half. Mr. Bouguer judciouſly remarks, that the greateſt mountain is a trifle coimpared to the vaſt body of the terreſtrial globe; and that a hundred obſervations, where no ſenſible attraction is found, prove nothing againſt the Newtonian ſyſtem; but that this made at the foot of the vaſt mountain Chimboraco, which is in favour of the doctrine of attraction, deſerves the attention of all philoſophers.

ATTRACTIVE, ſomething that has the power or property of attraction.

ATTRACTIVES, or ATTRACTIVE *Medicines*, a name given by ſome writers to what are otherwiſe called *digeſtives*, *drawers*, *&c.*

ATTRIBUTE, in a general ſenſe, implies a quality belonging to ſome perſon or thing. Thus, underſtanding is an attribute of the mind, and extenſion an attribute of body.

The word is Latin, *attributum*, and compounded of *ad*, to, and *tribuo*, to give, or aſcribe.

ATTRIBUTES, in theology, the ſeveral qualities or perfections of the divine nature, which conſtitute his eſſence.

The heathen mythology divided the deity into as many diſtinct beings as he had attributes. Thus the power of God was called Jupiter, the wrath and vengeance of God, Juno, &c. But true religion and ſound philoſophy have taught the world to conſider the ſeveral attributes of God as one entire perfection; which, though it exerts itſelf in different ways and actions, and conſequently admits of divers names, ſuch as wiſdom, goodneſs, mercy, &c. yet is in itſelf but one ſimple indiviſible principle of action, whoſe operations are all uniform and harmonious.

ATTRIBUTES, in logic, are the predicates of any ſubject, or what may be affirmed or denied of any thing.

ATTRIBUTES, in painting and ſculpture, ſignifies the ſymbols added to ſeveral figures to intimate their particular office and character. Thus the eagle is the attribute of Jupiter; a peacock of Juno; a caduce of Mercury; a club of Herculus; a trumpet of Fame; a balance of Juſtice; and a palm of Victory.

ATTRITION, in a general ſenſe, implies the rubbing or ſtriking of bodies one againſt another, ſo as to throw off ſome of their ſuperficial particles.

The word is Latin, *attritio*, and derived from *adtero*, to rub againſt.

The grinding or poliſhing of bodies is performed by attrition, the effects of which are heat, light, fire, and electricity.

ATTRITION is often uſed for the friction of ſuch ſimple bodies as do not wear from rubbing againſt one another; but whoſe fluids are, by that motion, ſubjected to ſome particular determination; as the various ſenſations of hunger, pain, and pleaſure, are ſaid to be occaſioned by the attrition of the organs formed for ſuch impreſſions.

ATTRITION, among divines, ſignifies a ſorrow or repentance for having offended God, ariſing chiefly from the apprehenſions of puniſhment, the loſs of heaven, and the torments of hell; and differs from contrition, inaſmuch as this laſt is conceived to ariſe from a love to God, as an ingredient or chief motive to our ſorrow and repentance. See the article CONTRITION.

AVAUNCHERS, among hunters, the ſecond branches of a deer's horn.

AUBIN, in horſemanſhip, a kind of broken pace, between an amble and a gallop. It is reckoned a defect.

AUCTION, *Auctio*, a kind of public ſale, very much in uſe for houſhold goods, books, plate, &c. By this method of ſale, the higheſt bidder is always the buyer.

This was originally a kind of ſale among the ancient Romans, performed by the public crier, *ſub haſta*, i. e. under a ſpear, ſtuck up on that occaſion by ſome magiſtrate, who made good the ſale by delivery of the goods.

AUDIANISM, the ſame with anthropomorphiſm, or the doctrine of the anthropomorphites. See the article ANTHROPOMORPHITES.

AUDIENCE, in a general ſenſe; ſee the article HEARING.

AUDIENCE given to ambaſſadors, implies the ceremonies obſerved in courts, at the admiſſion of ambaſſadors, or public miniſters, to a hearing.

In England, audience is given to ambaſſadors in the preſence-chamber; to envoys and reſidents, in a gallery, cloſet, or in any place where the king happens to be. Upon being admitted, as is the cuſtom of all courts, they make three bows, after which they cover and ſit down;

but not before the king is covered and ſat down, and given them the ſign to put on their hats.

When the king does not care to have them covered, and ſit, he himſelf ſtands uncovered; which is taken as a ſlight.

At Conſtantinople, miniſters uſually have audience of the grand vizier.

Audience is alſo the name of a court of Juſtice eſtabliſhed in the Weſt-Indies by the Spaniards, anſwering in effect to the parliament in France.

Theſe courts take in ſeveral provinces, called alſo audiences from the names of the tribunal to which they belong.

Audience is alſo the name of an eccleſiaſtical court held by the archbiſhop of Canterbury, wherein differences upon elections, conſecrations, inſtitutions, marriages, &c. are heard.

AUDIENDO & TERMINANDO, a writ, or more properly a commiſſion, directed to certain perſons, when any riotous aſſembly, inſurrection, &c. is committed in any place for appeaſing it, and puniſhing the offenders.

AUDIENTES, an order of catechumens, in the primitive Chriſtian church, conſiſting of ſuch as were but newly inſtructed in the myſteries of the Chriſtian religion, and not yet admitted to baptiſm.

AUDIT, a regular hearing and examination of an account by ſome proper officers appointed for that purpoſe.

AUDITA QUERELA, a writ that lies uſually where one is bound in a ſtatute merchant, ſtatute ſtaple, or recognizance, when a perſon has any thing to plead, but hath not a day in a court for pleading it; or where judgement is given for debt, and the defendant's body in execution; then if he have a releaſe, or other ſufficient cauſe to be diſcharged therefrom, but wants a day in court to plead the ſame, this writ may be granted him againſt the perſon that has recovered, or againſt his executors.

This writ is granted by the lord chancellor, upon view of the exception ſuggeſted to the judges of either bench, willing them to grant ſummons to the ſheriffs of the county where the creditor is, for his appearance, at a certain day, before them.

AUDITOR, in a general ſenſe, a hearer, or one who liſtens and attends to any thing.

Auditor is alſo uſed for ſeveral officers appointed to audit. See Audit.

It was anciently uſed for a judge. Notaries are alſo frequently called auditores.

Auditor, according to our law, is an officer of the king, or ſome other great perſon, who, by examining yearly the accounts of the under-officers, makes up a general book, with the difference between their receipts and charges, and their allowances or allocations.

Auditor *of the Receipts* is an officer of the exchequer who files the tellers bills, makes an entry of them, and gives the lord-treaſurer a certificate of the money received the week before. He alſo makes debentures to every teller before they receive any money, and takes their accounts. He keeps the black-book of receipts, and the treaſurer's key of the treaſury, and ſees every teller's money locked up in the new treaſury.

Auditors *of the Revenue*, or *of the Exchequer*, officers who take the accounts of thoſe who collect the revenues and taxes raiſed by parliament, and take the accounts of the ſheriffs, eſcheators, collectors, tenants, and cuſtomers, and ſet them down in a book and perfect them.

Auditors *of the preſt and impreſt*, are officers of the exchequer, who take and make up the account of Ireland, Berwick, the Mint, and of any money impreſſed to any man for the king's ſervice.

Auditors *Collegiate*, *Conventual*, *&c.* officers formerly appointed in colleges, &c. to examine and paſs their accounts.

AUDITORY, ſomething relating to the ſenſe of hearing. See the article Hearing.

Auditory, or Audience, an aſſembly of people who attend to hear a perſon that ſpeaks in public.

Auditory is alſo uſed for the bench whereon a magiſtrate or judge hears cauſes.

Auditory was alſo the place in ancient churches where the congregation ſtood to hear ſermons.

Meatus Auditorius, auditory paſſage, in anatomy; ſee Meatus *Auditorius*.

Auditory *Nerves*, in anatomy, a pair of nerves ariſing from the medulla oblongata, with two trunks, the one of which is called the portio dura, or hard portion, the other portio mollis, or ſoft portion. See the article Nerve.

The portio mollis enters the foramen of the os petroſum, and thence through various little apertures, gets into the labyrinth of the ear, where it expands over all its parts, and conſtitutes the primary organ of hearing.

The portio dura, paſſing the aquæduct of Fallopius, turns back one or more branches from the anterior ſurface of the proceſs of the petroſum, into the cavity of the cranium. It ſends off alſo another branch internally, which with the branch from the fifth pair, ſerves for the conſtruction of the chorda tympani. It alſo ſends off a number of other ſmall ramifications, which run to the muſcles and other parts of the tympanum.

AVE-MARIA, the angel Gabriel's ſalutation of the Virgin Mary, when he brought her the tidings of the incarnation.

It is become a prayer, or form of devotion, in the Romiſh church. Their chaplets and roſaries are divided into ſo many ave-maries, and ſo many pater-noſters, to which the papiſts aſcribe a wonderful efficacy.

Dr. Bingham obſerves, that among all the ſhort prayers uſed by the primitive Chriſtians before their ſermons, there is not the leaſt mention of an ave-maria.

AVENA, the Oat, in botany; ſee the article Oat.

AVENOR, an officer belonging to the king's ſtables, who provides oats for the horſes. He acts by warrant from the maſter of the horſe. See the article Master *of the Horſe*.

AVENUE, in gardening, a walk planted on each ſide with trees, leading to an houſe or wood, &c.

The Engliſh elm will do in all grounds, except ſuch as are very wet and ſhallow; and this is preferred to all other trees, becauſe it will bear cutting, heading or lopping in any manner, better than moſt others. The rough or ſmooth Dutch elm is approved by ſome, becauſe of its quick growth: this is a tree that will bear removing very well; it is alſo green almoſt as ſoon as any plant whatever in ſpring, and continues ſo as long as any; and it makes an incomparable hedge, and is preferable to all other trees for lofty eſpaliers, The lime is valuable for its regular growth, and fine ſhade. The horſe cheſnut is proper for all places that are not much expoſed to rough winds. The common cheſnut will do very well in a good ſoil, and riſes to a conſiderable height, when planted ſomewhat cloſe, though, when it ſtands ſingle, it is rather inclined to ſpread than grow tall. The beech is a beautiful tree, and naturally grows well with us in its wild ſtate; but it is leſs to be choſen for avenues than the beforementioned, becauſe it does not bear tranſplanting well, but is very ſubject to miſcarry. Laſtly, the abele is fit for any ſoil, and is the quickeſt grower of any foreſt-tree. It ſeldom fails in tranſplanting, and ſucceeds very well in wet ſoils, in which the others are apt to fail. The oak is but little uſed for avenues, becauſe of its ſlow growth.

The old method of planting avenues was with regular rows of trees, and this has been always kept ſo till of late; but we have now a much more magnificent way of planting avenues: this is by ſetting the trees in clumps or platoons, making the opening much wider than before, and placing the clumps of trees at about 300 feet diſtant from one another. In each of theſe clumps there ſhould be planted either ſeven or nine trees; but it is to be obſerved, that this is only to be practiſed where the avenue is to be of ſome conſiderable length; for, in ſhort walks this will not appear ſo ſightly as ſingle rows of trees. The avenues made by clumps are fitteſt of all for parks. The trees in each clump ſhould be planted 30 feet aſunder, and a trench ſhould be thrown up round the whole clump, to prevent the deer from coming to the trees to bark them. *Miller's Dict.*

Avenue, in fortification, an opening or inlet into a fort, baſtion, or the like. See the article Bastion.

AVERAGE, in law, an ancient ſervice which the tenant owed to his lord, by horſe or carriage.

AVERAGE, in commerce, ſignifies the accidents and misfortunes which happen to ſhips and their cargoes, from the time of their loading and ſailing, to their return and unloading; and it is divided into three kinds. 1. The ſimple or particular average, which conſiſts in the extraordinary expences incurred for the ſhip alone, or for the merchandizes alone. Such is the loſs of anchors, maſts, and rigging, occaſioned by the common accidents at ſea; the damages which happen to merchandize by ſtorm, prize, ſhipwreck, wet or rotting; all which muſt be borne and paid by the thing which ſuffered the damage. 2. The large and common average, being thoſe expences incurred, and damages ſuſtained for the common good and ſecurity both of the merchandizes and veſſels, conſequently to be borne by the ſhip and cargo, and to be regulated upon the whole. Of this number are the goods or money given for the ranſom of the ſhip and cargo, things thrown over-board for the ſafety of the ſhip, the expences of unlading for entering into a river or harbour, and the proviſions and hire of the ſailors, when the ſhip is put under an embargo. 3. The ſmall averages, which are the expences for towing and pilotting the ſhip out, or into harbours, creeks, or rivers, one third of which muſt be charged to the ſhip, and two thirds to the cargo.

Average is more particularly uſed for a certain contribution, that merchants make proportionably towards their loſſes. It alſo ſignifies a ſmall duty which thoſe merchants, who ſend goods in another man's ſhip, pay to the maſter for his care of them over and above the freight. Hence it is expreſſed in the bills of lading, paying ſo much freight for the ſaid Goods, with primage and average, accuſtomed.

AVERAGE, in agriculture, a term uſed by the farmers in many parts of England, for the breaking of corn-fields, eddiſh, or roughings.

The word in the firſt or law ſenſe is derived from *averium*, a labouring beaſt: in the ſecond, or mercantile ſenſe, from *averia*, goods, or chattels; from the French *avoir*, to have or poſſeſs. In the laſt, or the farmer's ſenſe, it may be derived from *haver*, an Engliſh name for oats.

AVER-CORN, that conveyed to the lord's granaries by his tenants.

AVERDUPOIS, or AVERDUPOISE *Weight*, a weight much uſed in England, and whoſe pound conſiſts of ſixteen ounces. See the article WEIGHT.

AVERIA, a general name for cattle of any kind; but, in law, is confined to oxen and horſes of the plough.

AVER-LAND, that plowed by the tenants for the uſe of their lord.

AVERMENT, an offer of the defendant to make good an exemption pleaded in abatement, or bar of the plaintiff's action.

General AVERMENT is the concluſion of every plea to the writ, or in bar of replications, or other pleadings, containing affirmative matter.

Particular AVERMENT is when the life of a tenant for life, or a tenant in tail, is averred.

AVERNI, among the ancient naturaliſts, implied certain lakes, grottoes, and other places, which infect with poiſonous ſteams or vapours.

AVER-PENNY, money paid inſtead of average.

AVERRHOA, in botany, a genus of plants, whoſe flower conſiſts of five lanceolated petals; the fruit is an apple of a turbinated and obtuſe pentagonal figure, containing five cells, in which are diſpoſed angular ſeeds, ſeparated by membranes.

AVERRHOISTS, a ſect of Peripatetic philoſophers, who appeared in Italy ſome time before the reſtoration of learning, and attacked the immortality of the ſoul.

They took their denomination from Averrhoes, a celebrated interpreter of Ariſtotle, born at Cordova in Spain, in the 12th century, from whom they borrowed their diſtinguiſhing doctrine. The founder of this ſect, Averrhoes, is ſometimes called the Commentator, by way of eminence, as being ſuppoſed to have entered beſt of all the commentators into the ſentiments of the philoſopher; inſomuch that ſome have pretended the ſoul of Ariſtotle had migrated into the body of Averrhoes.

The Averrhoiſts, who held the ſoul was mortal, according to reaſon or philoſophy, yet pretended to ſubmit to the Chriſtian theology, which declares it immortal. But the diſtinction was held ſuſpicious; and this divorce of faith from reaſon was rejected by the doctors of that time, and condemned by the laſt council of the Lateran, under Leo X. yet it was ſtill ſecretly maintained. Pomponatius, Cæſalpinus, and others, were ſuſpected of favouring this opinion; but the corpuſcular philoſophy, now introduced into Italy, ſeems almoſt to have extinguiſhed Averrhoiſm.

AVERRUNCATION, in the ancient agriculture, ſignified the ſame with pruning. See the article PRUNING.

AVERRUNCI, in the ancient mythology, an order of deities, whoſe peculiar office it was to avert misfortunes. Apollo and Hercules were of this order among the Greeks, and Caſtor and Pollux among the Latins.

The word is Latin, and compounded of *a*, from, or away, and the obſolete verb *verrunco*, to turn.

AVERTI, in the manege, implies ſuch a pace in a horſe as is regulated and required in the leſſons.

AUGES, in aſtronomy, the ſame with apſides. See APSIS.

AUGMENT, *Augmentum*, in grammar, an accident of certain tenſes of Greek verbs, being either the prefixing a ſyllable, or the encreaſe of the quantity of the initial vowels.

There are two ſpecies of augments, diſtinguiſhed by the epithets *temporale* and *ſyllabicum*. The *augmentum temporale* is when a ſhort vowel is changed into a long one, or a diphthong into another of greater length: an *augmentum ſyllabicum*, is when a ſyllable is added at the beginning of a word.

AUGMENTS, in mathematics, the ſame with increments. See FLUXIONS and INCREMENTS.

AUGMENTATION, in a general ſenſe, implies the act of adding or joining ſomething to another, in order to increaſe its magnitude, or render it more conſiderable.

The word is Latin, *augmentatio*, and derived from *augeo*, to increaſe.

Court of AUGMENTATION, a court erected in the 27th year of Henry VIII. to take care that the revenues of the crown were properly augmented by the eſtates ariſing from the ſuppreſſion of religious houſes. This court was diſſolved in the firſt year of the reign of queen Mary; but the office in which are many valuable records, ſtill remains.

AUGMENTATION, in heraldry, are additional charges to a coat armour, frequently given as particular marks of honour, and generally borne either on the eſcutcheon or a conton. Thus all the baronets of England bear the arms of Ulſter in Ireland.

AUGRE, or AWGRE, an inſtrument uſed by carpenters, millwrights, &c. for boring large round holes. It conſiſts of a wooden handle and an iron blade, terminated with a ſteel bit.

AUGURS, among the old Greeks and Romans, were officers appointed to foretel future events by the chattering and feeding of birds, &c. There was a college, or community, of them, conſiſting originally of three members, with reſpect to the three tribes, the Luceres, Rhamnenſes, and Tatienſes: afterwards the number was increaſed to nine, four of them patricians, and five plebeians: this was in the conſulſhip of M. Valerius, and Q. Apuleius. They bore an augural ſtaff, or wand, as the enſign of their authority. Cicero was of the college of Augurs.

AUGURY, in its firſt and proper ſenſe, the art of foretelling future events by the chattering, ſinging, and feeding of birds; but in its more general ſignification, compriſing all the different kinds of divination; which Varro diſtinguiſhes into four ſorts, according to the four elements; viz. Pyromancy, or augury by fire; Aeromancy, or augury by air; Hydromancy, or augury by water; and Geomancy, or augury by the earth. It was a very ancient ſuperſtition; for we find it forbidden by Moſes. It was in great eſteem among the Chaldæans, from whom the Greeks learned it; and from them the Tuſcans had ſo high a value for this art, that, by a decree of the ſenate, it was ordered, that the advice of the augurs ſhould be held ſacred, and never deviated from. But what opinion the wiſer Romans had of the art, appears from the ſaying of Cato, recorded by Cicero, that he wondered how two augurs could meet, without laughing in each other's face.

The place from whence auguries were taken, was a riſing-ground; and Servius, on Virgil, obſerves, that there was a field ſet apart for it, at a little diſtance from Rome. When all things were diſpoſed for taking an augury, the augur entered into his tent or pavillion, habited in his robe, and holding his augural ſtaff in his hand; with which he divided the heavens into four parts, drawing a line from eaſt to weſt, and another croſs it from north to ſouth: then he ſacrificed to the gods, and offered up a prayer, after which he returned to his ſeat, and obſerved with great attention from what part, and in what manner, the ſign from heaven appeared. If, for inſtance, there happened lightning, or a clap of thunder, from the left, it was taken for a favourable preſage.

But the principal kind of augury, and from which it has its name, was the obſervation of birds; to which the ancients were ſo ſuperſtitiouſly addicted, that they never would undertake any thing of the leaſt importance, without conſulting theſe feathered oracles. The invention of this art is by ſome aſcribed to Prometheus; by others to Orpheus.

The Romans, whenever they went to war, not only conſulted the chattering and flight of birds, but their manner of feeding likewiſe; for which purpoſe they kept poultry, which they commonly fetched from the iſland of Eubœa. When they would take a preſage from thence, they flung corn before them: if the ſacred chickens crowed about it, and ate it greedily, it was looked upon as a favourable omen; but if they refuſed to eat or drink, it was an unlucky ſign.

AUGUST, in chronology, the eighth month of the year, according to our method of computing, beginning with January: but it was the ſixth with the Romans, who, for that reaſon called it Sextilis; which name was changed to Auguſt, from Auguſtus Cæſar, becauſe this emperor, being returned from the Gauls in the 746th year of Rome, endeavoured to reform the calendar; and in honour of him, Sextilis was changed to Auguſt. Others alledge, the reaſon was becauſe he was firſt made conſul in this month, and becauſe he gained great victories in it. The Turks have alſo taken this name from the Greek or Roman calendars, ſince they call it Agoſtos.

AUGUSTALES, in Roman antiquity, an epithet given to the flamens or prieſts appointed to ſacrifice to Auguſtus, after his deification, and alſo to the ludi or games celebrated in honour of the ſame prince, on the fourth of the ides of October.

AUGUSTALIA, a feſtival inſtituted by the Romans, in honour of Auguſtus Cæſar, on his return to Rome, after having ſettled peace in Sicily, Greece, Syria, Aſia, and Parthia; on which occaſion they likewiſe built an altar to him, inſcribed *Fortunæ reduci.*

AUGUSTALIS PRÆFECTUS, a title peculiar to a Roman magiſtrate who governed Egypt, with a power much like that of a pro-conſul in other provinces.

AUGUSTAN, in a general ſenſe, denotes ſomething relating to the emperor Auguſtus. Thus, we ſay, Auguſtan age, Auguſtan æra, &c.

AUGUSTINE MONKS, a religious order in the church of Rome, who followed the pretended rule of St. Auguſtin, preſcribed them by pope Alexander IV. in the year 1256. There had ariſen ſeveral religious orders in the thirteenth century, as the preaching brothers, founded by Dominic Guzman; the minims, by St. Francis Aſſiſſius; and others. Innocent IV. formed a deſign of uniting ſeveral of theſe orders into one; which deſign was executed by his ſucceſſor Alexander IV. who made one congregation of them, under the name of Auguſtin hermits.

At preſent the order is divided into ſeveral branches; as the hermits of St. Paul; the Ieronymitans; the monks of St. Bridget; and the bare-footed Auguſtins, inſtituted by a Portugueſe, in 1574, and confirmed by pope Clement VIII. in 1600. As to the rule of St. Auguſtin, which they pretend to follow, it is briefly this: The monks are to have all things in common: the rich, who enter into the order, are to ſell their poſſeſſions, and give them to the poor: nothing is to be received, without leave of the ſuperior; if it happens that the monks are obliged, through perſecution to retire, they are to betake themſelves immediately to the place whither their ſuperior is withdrawn: they are to employ the firſt part of the morning in labouring with their hands, and the reſt in reading: they have Saturday allowed them to provide themſelves with neceſſaries, and are permitted to drink wine on Sundays. When they go abroad, they muſt always go two in a company: they are never to eat but in their monaſtery: they are forbidden to harbour the leaſt thought of women: they are to receive no letters or preſents in ſecret. Theſe, with ſeveral other precepts relating to charity, modeſty, chaſtity, and other Chriſtian virtues, conſtitute what they call the rule of St. Auguſtin, which is read in the preſence of the monks once every week. The Auguſtins are cloathed in black. At Paris, they are known under the name of the religious of St. Genevieve, that abbey being the chief of the order. There are nuns likewiſe of this order.

AUGUSTINUS, the name of Janſenius's treatiſe, from which are collected the five famous propoſitions enumerated under the article Janſeniſm. See JANSENISM.

AVIARY, a place ſet apart for feeding and propagating birds. It ſhould be ſo large, as to give the birds ſome freedom of flight; and turfed, to avoid the appearance of foulneſs on the floor.

AVIS, the name of an order of knighthood in Portugal, inſtituted by Sancho the firſt king, in imitation of the order of Alcantara, whoſe green croſs they wear.

AULA is uſed for a court baron, by Spelman; by ſome old eccleſiaſtical writers, for the nave of a church, and ſometimes for a court yard.

AULIC, an epithet given to certain officers of the empire, who compoſe a court, which decides, without appeal, in all proceſſes entered in it. Thus we ſay, aulic council, aulic chamber, aulic counſellor.

The aulic council is compoſed of a preſident, who is a catholic; of a vice-chancellor, preſented by the archbiſhop of Mentz; and of eighteen counſellors, nine of whom are proteſtants, and nine catholics. They are divided into a bench of lawyers, and always follow the emperor's court, for which reaſon they are called *juſtitium imperatoris*, the emperor's juſtice, and aulic council. The aulic court ceaſes at the death of the emperor; whereas the imperial chamber of Spire is perpetual, repreſenting not only the deceaſed emperor, but the whole Germanic body, which is reputed never to die.

AULIC in the Sorbonne and foreign univerſities, is an act which a young divine maintains upon being admitted a doctor in divinity.

It begins by an harangue of the chancellor, addreſſed to the young doctor, after which he receives the cap, and preſides at the aulic, or diſputation.

AULNEGER, or ALNAGER. See the article ALNAGER.

AULOS, αυλος, a Grecian long-meaſure; the ſame with ſtadium. See STADIUM.

AUMBRY, a country word denoting a cupboard. See CUPBOARD.

AUME, a Dutch meaſure for Rheniſh wine, containing forty Engliſh gallons.

AUNCEL WEIGHT, an ancient kind of ballance, now out of uſe, being prohibited by ſeveral ſtatutes, on account of the many deceits practiſed by it. It conſiſted of ſcales hanging on hooks, faſtened at each end of a beam, which a man lifted up on his hand. In many parts of England, auncel-weight ſignifies meat ſold by the hand, without ſcales.

AUNE, a long-meaſure uſed in France to meaſure cloth, ſtuffs, ribbons, &c.

At Rouen it is equal to one Engliſh ell, at Calais to 1.52, at Lyons to 1.016, and at Paris to 0.95.

AVOCATORIA, a mandate of the emperor of Germany, addreſſed to ſome prince, in order to ſtop his unlawful proceedings in any cauſe appealed to him.

AVOIDANCE, in the canon law, is when a benefice becomes void of an incumbent, which happens either in fact, as by the death of the parſon, or in law, as by ceſſion, deprivation, reſignation, &c. In the firſt of theſe caſes, the patron muſt take notice of the avoidance, at his peril; but in avoidance by law, the ordinary is obliged to give notice to the patron, in order to prevent a lapſe.

AVOWEE, one who has a right to preſent to a benefice. See ADVOWSON.

He is thus called in contradiſtinction to thoſe who only have the lands to which the advowſon belongs for a term of years, or by virtue of intruſion or diſſeiſin. See the article INTRUSION, &c.

AVOWRY, in law, is when a perſon diſtrained ſues out a replevin; for then the diſtrainer muſt avow, and juſtify his plea, which is called his avowry. See the article REPLEVIN.

The avowry muſt contain ſufficient matter for judgment to have return, but ſo much certainty is not required therein, as in a declaration; and if made for rent, though it appears that part of that rent is not due, yet the avowry is good for the reſt.

AURA, in chemiſtry, a certain fine and pure ſpirit, found in every animal or vegetable body; but ſo ſubtile, as only to be ſuſceptible by its ſmell and taſte, or other effects, not found in any other but that body. This aura exhibits the proper characters of the body, by which it is accurately diſtinguiſhed from all others; but is itſelf too fine and thin to be ſeen by the eyes, though armed with a microſcope; or felt by the hands; and withal, is extremely volatile; ſo that, when pure and ſingle, it flies off by its great mobility, mixes with the air, and is received into the great chaos of all volatiles; and there, ſtill retaining its ſame nature, it floats till it falls down in ſnow, hail, rain, or dew, when it again enters the boſom of the earth, impregnates it with its prolific virtue, and is at length received by other juices of the earth, and conveyed into the bodies of animals and vegetables; and, by this revolution, paſſes into new bodies, whoſe maſs it animates and directs. The ſubtle fluid is lodged in the oil of the body, to prevent its being diſſipated and thrown off; and hence it is, that all the ancient alchymiſts ſay, ſpirit reſides in ſulphur. *Boerh. Chem.*

AURANTIUM, in botany, the orange. See the article ORANGE.

AURELIA, in natural hiſtory, the ſame with what is more uſually called chryſalis, and ſometimes nymph. See the articles CHRYSALIS and NYMPH.

AUREOLA, in its original ſignification, ſignifies a jewel which is propoſed as a reward of victory in ſome public diſpute. Hence the Roman ſchoolmen applied it to denote the reward beſtowed on martyrs, virgins, and doctors, on account of their works of ſupererogation: and painters uſe it to ſignify the crown of glory, with which they adorn the heads of ſaints, confeſſors, &c.

AUREUS, a Roman gold coin, equal in value to twenty-five denarii.

According to Ainſworth, the aureus of the higher empire weighed near five penny-weight; and in the lower empire, little more than half that weight. We learn from Suetonius, that it was cuſtomary to give aurei to the victors in the chariot-races.

AURICLE, in anatomy, that part of the ear, which is prominent from the head, called by many authors auris externa. See the article EAR.

AURICLES *of the Heart*. Theſe are a kind of appendages of the heart at its baſe, and are diſtinguiſhed by the names of the right and left. The right auricle is much larger than the left, and this is placed in the hinder, that in the anterior part. They are intended as diverticula for the blood, during the ſyſtole. Their ſubſtance is muſcular, being compoſed of ſtrong fibres, and their motion is not ſynchronous, but achronous with that of the heart. See the article HEART.

AURICULAR, whatever belongs or relates to the ear. Thus we ſay, auricular witneſs, auricular confeſſion, &c. as being done ſecretly, and as it were in the ear.

AURICULAR *Medicines*, ſuch as are uſed in the cure of diſtempers in the ear. See the article EAR.

AURICULARIS *Digitus*, the little finger, ſo called, becauſe it is commonly uſed to pick the ear.

AURIGA, the WAGGONER, in aſtronomy, a conſtellation of the northern hemiſphere, conſiſting of twenty-three ſtars, according to Tycho; forty according to Hevelius; and ſixty-eight in the Britannic catalogue.

AURIPIGMENTUM, ORPIMENT, in natural hiſtory. See ORPIMENT.

AURIS, the ear, in anatomy. See EAR.

AURISCALPIUM, an inſtrument to clean the ears, and ſerving alſo for any other operation in diſorders of that part.

AURORA, the morning twilight, or that faint light which appears in the morning, when the ſun is within eighteen degrees of the horizon.

AURORA, the goddeſs of the morning, according to the pagan mythology. She was the daughter of Hyperion and Theia, according to Heſiod; but of Titan and Terra, according to others. It was under this name that the ancients deified the light, which foreruns the riſing of the ſun above our hemiſphere. The poets repreſent her as riſing out of the ocean, in a chariot, with roſy fingers dropping gentle dew. Virgil deſcribes her aſcending in a flame-coloured chariot with four horſes.

AURORA *Borealis*, the northern dawn or light; a remarkable meteor of a luminous appearance, often viſible during the night in the northern parts of the heavens.

This meteor exhibits a great variety of phænomena, of which the following are the principal.

1. In the northern part of the horizon there is commonly the appearance of a very black cloud; we ſay appearance, becauſe it is evidently no real cloud, the ſmalleſt ſtars being viſible through it. This apparent cloud is extended ſometimes farther towards the weſt than towards the eaſt; ſometimes farther towards the eaſt than towards the weſt; and generally takes up about a quarter of the horizon.

2. The upper edge of this cloud is generally terminated by a very lucid arch, from one to four or five degrees broad, whoſe center is below the horizon. Sometimes there are two or more of theſe arches, one above another. In ſome the cloud is not terminated by an arch, but by a long ſtreak of light lying parallel to the horizon. The limb of this luminous arch, or parallel ſtreak, is not always even and regular, but ſinks lower in ſome parts than in others.

3. Out of this arch proceed ſtreams of light, generally perpendicular to the horizon, but ſometimes a little inclined to it. Moſt of them ſeem to end in a point, like pyramids or cones, and often very much reſemble the tails of comets. Sometimes there is no luminous arch, nor ſtreak of light; and then the ſtreams ſeem to iſſue out from behind the dark cloud, being diſtinct from each other at their baſes.

4. The upper ends of the ſtreams inceſſantly appear and vaniſh again, as quick as if a curtain were drawn backwards and forwards before them; which ſometimes cauſes ſuch a ſeeming trembling in the air, that the upper part of the heavens were, if we may be allowed the expreſſion, in convulſions.

5. They ſometimes ſeem to meet in the zenith, or more commonly about ten degrees to the ſouthward of it, and there curling round, they, in ſome meaſure, imitate a flame confined under an arch; and being frequently tinged with various colours, exhibit a moſt beautiful appearance, reſembling a canopy finely painted, of about ten or twenty degrees in breadth.

In many auroras there are ſtreams aſcending from theſe parts of the heavens, which lie ſeveral degrees to the ſouthward of the canopy; and in ſome they appear to ariſe, though very rarely, almoſt as large and numerous from the ſouthern as from the northern parts of the horizon.

6. The height of the aurora borealis is very great; for that on the 6th of March 1715, was viſible from the weſt ſide of Ireland, to the confines of Ruſſia and Poland to the eaſt; and perhaps much further; extending at leaſt over thirty degrees of longitude, and in latitude from about the fiftieth degree over almoſt all the north of Europe, and exhibiting, nearly at the ſame time, the ſame appearances at all places.

7. Theſe phænomena have always been very frequent in countries near the frigid zone, but very rare in our latitude,

latitude. They are now however become very frequent with us, but always ſeem to proceed from the north; and are as yet unknown to the inhabitants of the more ſouthern parts of our hemiſphere. Whether they are known to thoſe who inhabit the ſouthern frigid zone, is yet undetermined.

8. In ſome there are trains of light running horizontally, ſometimes from the middle of the extremes, and ſometimes with one extreme to another: and from theſe trains ſtreams perpendicular to the horizon often ariſe, and accompany them as they paſs along.

9. When all the ſtreaming is over, the aurora borealis commonly degenerates into a bright twilight in the north, and there gradually dies away.

10. It is probable theſe phænomena often happen in cloudy nights, though we are not ſenſible of them; for it is obſervable that in ſuch nights there is frequently more light than what uſually proceeds from the ſtars alone.

The moſt obvious ſolution of the aurora borealis, or at leaſt what would appear ſo to thoſe who have only attended to the circumſtances of ſome particular meteors of this kind, is, that it is a thin nitro-ſulphureous vapour, raiſed in our atmoſphere, conſiderably higher than the clouds; that this vapour, by fermentation, takes fire, and the exploſions of one portion of it kindling the next, the flaſhes ſucceed one another till the whole quantity of vapour within their reach is ſet on fire.

Some have thought that vapours rarefied exceedingly by ſubterraneous fire, and tinged with ſulphureous ſteams, might thence be diſpoſed to ſhine in the night, and riſing up to the top of the atmoſphere, or even beyond its limits, might produce thoſe undulations in the air, which conſtitute this phænomenon. But theſe hypotheſes have been rejected, as inſufficient; it having been thought impoſſible to account for all the circumſtances from them.

Dr. Halley therefore thought proper to have recourſe to the magnetic effluvia of the earth, which he ſuppoſes to perform the ſame kind of circulation with regard to it, as the effluvia of any particular terrella do with reſpect to that, viz. that they enter the earth near the ſouth pole, and, pervading its pores, paſs out again at the ſame diſtance from the northern: and thinks, they may ſometimes, by the concourſe of ſeveral cauſes, very rarely coincident, and to us as yet unknown, be capable of producing a ſmall degree of light, either from the greater denſity of the matter, or perhaps from the greater velocity of its motion; after the ſame manner as we ſee electrical bodies emit light in the dark.

M. de Mairan has given us a phyſical and hiſtorical treatiſe on the aurora borealis, and endeavours to prove, that it is owing to the zodiacal light, or the atmoſphere of the ſun, ſpread on each ſide of it along the zodiac, in the form of a pyramid. This he ſays is ſometimes extended to ſuch a length as to reach beyond the orbit of our earth, and then by mixing itſelf with our atmoſphere, and being of a heterogeneous nature, produces the ſeveral appearances obſervable in the aurora borealis.

We thought proper to mention theſe ſolutions, becauſe they come from two very ingenious philoſophers, though they are certainly too fine-ſpun to hold, and ſeem no other than the ingenious reveries of perſons determined to frame an hypotheſis at any rate. We may certainly find materials for the aurora borealis, without having recourſe either to the magnetical effluvia of the earth, or the zodiacal light, the nature of both which we are wholly unacquainted with. The effluvia continually exhaled from the ſurface of the earth, if rightly conſidered, will afford a very eaſy and natural ſolution, as we ſhall now endeavour to ſhew.

Firſt, We know from experiment, that there are ſome ſteams, as inflammable ſulphureous ones, which are capable of ſo great a degree of expanſion, that they will render themſelves lighter than the air they float in, even when that fluid is as rare as it can be rendered by art; for they will riſe to the top of an exhauſted receiver: ſuch ſteams, or exhalations, therefore, iſſuing from mines, volcanos, &c. in the bowels of the earth, muſt neceſſarily aſcend towards the top of the atmoſphere, at leaſt till they come to a region where the air is as rare and as much expanded as it can be made by the air-pump here below. This height, according to Dr. Halley's computation, founded on the refraction of a ray of light, is forty-four miles and a half (ſee ATMOSPHERE): but may probably be much greater; for the air is higher than any vapours capable of refracting a ray of light can aſcend.

Secondly, Theſe effluvia being raiſed to the top of the atmoſphere, or near it, and floating there, will neceſſarily be carried towards the polar regions, for the following reaſons. 1. Becauſe the ſuperior current of the air, at a great diſtance from the equator, tends that way. 2. We know from experiment that whatever ſwims upon a fluid, which revolves about an axis, is by that very motion carried towards the extremities of that axis. This is exactly the caſe of theſe effluvia; for they float near the top of the atmoſphere, which continually revolves about the axis of the earth; and muſt therefore be neceſſarily carried towards the polar regions. 3. Theſe effluvia being collected together, at or near the poles, and of an inflammable nature, may eaſily be ſuppoſed to ferment, when they meet with other heterogeneous particles proper for producing ſuch an effect, and emit fiery ſtreams, which will naturally riſe into ſuch parts of the atmoſphere as are ſtill lighter than that in which theſe corpuſcles naturally floated; that is, directly upwards from the center of the earth: but, according to the rules of perſpective, theſe ſtreams, though they really diverge as radii from a center, will appear to a ſpectator on the ſurface of the earth to converge towards a point; which point will ſeem to be directly over his head, if the ſtreams aſcend in right lines from the center of the earth; but if they deviate all one way from that direction, the point will be on that ſide the zenith towards which they incline. To illuſtrate this, let us ſuppoſe ſeveral ſtrings to hang down from the ceiling of a room, and a candle to be placed on a table below them: ſhadows of theſe threads will all converge towards the point on the ceiling immediately over the candle: and if they are made to incline from a perpendicular direction, ſuppoſe all one way, the point of convergency will remove from the ſpot immediately over the candle, towards that ſide of the room to which the upper ends of the ſtrings incline. Now, if a perſon had viewed them from the place where the candle was ſet, and referred their places to the ceiling, they would have appeared to have converged towards the ſame point to which their ſhadows were directed by the candle.

And if the ſtreams ſpread themſelves as they riſe, but not too much, they will ſtill appear tapering towards their upper-ends like cones or pyramids; juſt as the ſides of a long walk ſeem to a perſon viewing it from one end, to approach each other at the fartheſt extremity.

Hence every phænomenon of the aurora borealis may be eaſily accounted for; and its height may be calculated in the following manner.

Let the ſine of the elevation of the pole be $= q$, the ſine of the greateſt altitude of the lucid arch $= m$, the ſine of half the diſtance of the legs of the arch from each other, at the horizon $= g$, the ſemi-diameter of the earth $= a$, and the ſine of the angle, which is equal to the greateſt altitude of the arch, and the altitude of the equator taken together, be $= b$; thus the diſtance of the matter in the vertex of the arch, from an obſerver, will be expreſſed by $\frac{2amq^2g^2}{r^3b^2 - rg^2q^2}$.

AURUM, GOLD, in natural hiſtory; ſee the article GOLD.

The Latin term, *aurum*, is chiefly uſed to denote certain chemical preparations, whereof gold is the principal ingredient.

AURUM *Fulminans*, a chemical compoſition prepared by diſſolving gold in aqua regia, and precipitating the metal from the menſtruum, by adding a volatile alkali: after which the precipitated powder is edulcorated by frequent effuſions of warm water, and then dried in the ſhade.

The aurum fulminans, prepared in this manner, weighs about one fourth part more than the gold employed, three parts of gold yielding four of the fulminating powder;

according to Lemery, Kunckel, and other practical writers. Part of the increaſe proceeds from the volatile alkali; for, on adding to the aurum fulminans a little vitriolic acid, the volatile ſalt riſes in ſublimation, ſatiated with the acid: the remaining powder is found to be diveſted of its fulminating power. From the coalition of the volatile alkali with the nitrous acid in the menſtruum reſults an ammoniacal nitre, a ſalt which of itſelf detonates on being heated; but by what power or mechaniſm its detonating quality is ſo remarkably increaſed in the aurum fulminans, is unknown.

The exploſion of aurum fulminans is more vehement than of any other known kind of matter: it goes off in a leſs degree of heat than any of the other exploſive compoſitions; and even grinding it ſomewhat ſmartly in a mortar, is ſufficient for making it explode. Some inſtances are mentioned in the Breſlau collections, and the Ephemerides Naturæ Curioſorum, of a very ſmall quantity burſting in pieces the marble mortar in which it was rubbed; and an accident of the ſame kind happened ſome years ago to a ſkilful chemiſt here. The operator cannot therefore be too much on his guard in the management of ſo dangerous a preparation.

It has been reckoned, that a few grains of aurum fulminans act with as much force as ſeveral ounces of gunpowder: but the actions of the two are of ſo different kinds, that it is difficult to determine in what manner their ſtrength can be compared. The report of aurum fulminans is of extreme acuteneſs, offending the ear far more than that of a much larger quantity of gun-powder; but does not extend to ſo great a diſtance, ſeeming to differ from it as the ſound of a ſhort or tenſe muſical ſtring, from that of a long one, or of one which is leſs ſtretched. In ſome experiments made before the Royal Society, and mentioned in the firſt volume of Dr. Birch's hiſtory, aurum fulminans cloſed up in a ſtrong hollow iron ball, and heated in the fire, did not appear to explode at all; while gun-powder, treated in the ſame manner, burſt the ball. On the other hand, a little aurum fulminans, exploded on a metalline plate in the open air, makes an impreſſion or perforation in the plate; an effect which gunpowder could ſcarcely produce in any quantity.

This remarkable effect of aurum fulminans on the body which ſerves for its ſupport, has induced ſome to believe that its action is exerted chiefly or ſolely downwards. It appears, however, to act in all directions: for a weight laid upon it, either receives a like impreſſion, or is thrown off: and, in the collection above mentioned, an account is given of a large quantity (ſome ounces) which exploding from too great heat uſed in the drying of it, broke open the doors, and ſhattered the windows in pieces. Mr. Hellot found, that when a few grains of the powder were placed between two leaves of paper, and cemented to one of them by gum water, only the leaf which touched the powder was torn by the exploſion, and the other ſwelled out; and that when both were brought into cloſe contact with it, by preſſing them together, it tore them both; from whence he concludes, that the action of the aurum is greateſt on the bodies which it immediately touches. Both this property, and the acuteneſs of the report, may poſſibly depend upon one cauſe, the celerity of the expanſion: experiments have ſhewn, that the reſiſtance of the air, to bodies in motion, increaſes with the velocity of the body in a very high ratio; and perhaps the velocity with which aurum fulminans explodes, may be ſo great, that it is reſiſted by the air as by a ſolid maſs. *Lewis's Commercium Philoſophico-Technicum.*

AURUM *Muſivum*, or *Moſaicum*, a chemical preparation uſed by japanners in gilding their veſſels: it is made in the following manner.

Take of tin one pound, of flowers of ſulphur ſeven ounces, of ſal ammoniacum and purified quickſilver, each half a pound. Melt the tin, and add the quickſilver to it in that ſtate; and when the mixture is become cold, powder it, and grind it with the ſal ammoniacum and ſulphur, till the whole be thoroughly commixt. Calcine them in a mattraſs; and the other ingredients ſubliming, the tin will be converted into the aurum moſaicum; and will be found in the bottom of the glaſs like a maſs of bright fleaky gold powder: but if any black or diſcoloured parts appear in it, they muſt be carefully picked or cut out.

The ſal ammoniacum employed, ought to be perfectly white and clean; and care ſhould be taken, that the quickſilver be not ſuch as is unadulterate with lead, which may be known by putting a ſmall quantity in a crucible, into the fire, and obſerving when it is taken out, whether it be wholly ſublimed away, or have left any lead behind it. The calcination may be beſt performed in a coated glaſs body, hung in the naked fire; and the body ſhould be of a long figure, that the other ingredients may riſe ſo as to leave the coloured tin clear of them. The quickſilver, though it be formed into cinnabar along with the ſulphur, need not be waſted; but may be revived by diſtilling it with the addition of quick-lime.

AURUM *Potabile*, or tincture of gold, a medicine formerly of great requeſt, but at preſent rarely if ever uſed. It is prepared by mixing eſſential oil of roſemary with a ſolution of gold in aqua-regia; and, after ſhaking the veſſel, the gold will be retained in the oil, ſwimming on the top. This oil is ſeparated by inclination, and afterwards digeſted for a month in highly rectified ſpirit of wine.

But, after all, this is not a genuine tincture of gold, being only the gold divided into very ſmall parts by the ſpicula of the aqua-regia, ſwimming in the oil of roſemary; nor can there be any radical tincture of gold, which may not, by evaporating the oil, be reduced to a powder, and the powder by melting reduced into gold. The virtues of this tincture are entirely owing to the oil of roſemary.

AUSPICIUM. See AUGURY.

AUSTERE, rough, aſtringent. Thus an auſtere taſte is ſuch a one as conſtringes the mouth and tongue with ſome auſterity; as the taſte of unripe fruit.

Things of an auſtere taſte are ſuppoſed by ſome, from their glutinous quality, to generate the ſtone.

AUSTERITY, among moral writers, implies ſeverity and rigour. Thus we ſay, auſterity of manners.

Auſterity of bodies, according to the Carteſians, conſiſts in having obtuſe angular particles, like a blunt ſaw.

AUSTRAL, *Auſtralis*, ſomething relating to the ſouth: thus the ſix ſigns on the ſouth ſide of the equinoctial, are called auſtral ſigns.

AUSTRIA, a circle of Germany, comprehending the arch-dutchy of Auſtria, alſo Styria, Carinthia, Carniola, Tyrol, Trent, and Brixen.

It is bounded by Bohemia and Moravia on the north; by Hungary, Sclavonia, and Croatia on the eaſt; by the dominions of Venice on the ſouth; and by Bavaria on the weſt.

AUTER DROIT, in law, is when perſons ſue, or are ſued in another's right, as executors, guardians, &c.

AUTER FOIS ACQUIT, in law, a plea made by a criminal that he has been already acquitted of the ſame crime with which he is charged. There are likewiſe pleas of auter fois convict and attaint, that he has been before convicted of the ſame felony.

AUTHENTIC, ſomething of acknowledged and received authority. In law it ſignifies ſomething cloathed in all its formalities, and atteſted by perſons to whom credit has been regularly given. Thus, we ſay authentic papers, authentic inſtruments.

AUTHOR properly ſignifies one who created or produced any thing. Thus God, by way of eminence, is called the Author of nature, the Author of the univerſe.

The word author is ſometimes employed in the ſame ſenſe as inventor. As, Otho de Guerick is reported to be the author of the air-pump.

AUTHOR, in matters of literature, a perſon who has compoſed ſome book or writing.

Authors may be diſtinguiſhed into ſacred and profane, ancient and modern, known and anonymous, Greek, Latin, Engliſh, French, &c. and with regard to the ſubjects they treat, into divines, philoſophers, orators, hiſtorians, poets, grammarians, phyſiologiſts, &c. See the articles SACRED, PROFANE, &c.

An original author is he, who, in treating any ſubject, does not follow any other perſon, or imitate any model, either in the matter or method of his compoſition: for inſtance, M. de Fontenelle is an original author in his Plurality of Worlds, but not in his Dialogues of the Dead.

AUTHORITY, in a general ſenſe, ſignifies a right to command, and make one's ſelf obeyed. In which ſenſe, we ſay, the royal authority, the epiſcopal authority, the authority of a father, &c.

Authority denotes alſo the teſtimony of an author, ſome apophthegm, or ſentence of an eminent perſon, quoted in a diſcourſe by way of proof.

Authority, in law, ſignifies a power given by word, or writing, to a ſecond perſon to act ſomething, and may be by writ, warrant, commiſſion, letter of attorney, &c. and ſometimes by law. An authority given to another, to do what a perſon himſelf cannot do is void, and it muſt be for doing a thing that is lawful, otherwiſe it will be no good authority.

Authority is repreſented, in painting, like a grave matron ſitting in a chair of ſtate, richly clothed in a garment embroidered with gold, holding in her right hand a ſword, and in her left a ſceptre. By her ſide is a double trophy of books and arms.

AUTO DA FE, act of faith. The ceremony of putting in execution the ſeveral ſentences pronounced on criminals by the tribunal of the inquiſition. It is ſo called, becauſe it is conſidered, in thoſe countries where that tremendous court is ſettled, at the moſt illuſtrious and public proof that can be given of a zeal for religion and the Catholic faith. See Inquisiton.

AUTOCEPHALOUS, αυτοκεφαλοι, in church hiſtory, denotes archbiſhops who were independent of any patriarch.

AUTOGRAPH, αυτογραφον, denotes a perſon's handwriting, or the original manuſcript of any book, &c.

AUTOMATUM, or Automaton, αυτοματον, an inſtrument, or rather machine; which, by means of ſprings, weights, &c. ſeems to move itſelf as a watch, clock, &c. Such alſo were Archytus's flying dove, Regiomontanus's wooden eagle, &c.

AUTUMN, the third ſeaſon of the year, when the harveſt and fruits are gathered in. Hence, in the language of the alchemiſts, it ſignifies the time when the philoſophers ſtone is brought to perfection.

Autumn is repreſented, in painting, by a man at perfect age, cloathed like the vernal, and likewiſe girded with a ſtarry girdle; holding in one hand a pair of ſcales equally poized, with a globe in each; in the other, a bunch of divers fruits and grapes. His age denotes the perfection of this ſeaſon, and the ballance, that ſign of the zodiac, which the ſun enters when our autumn begins.

Autumnal, ſomething relating to autumn. Thus,

Autumnal *Point* is that point of the equinox from which the ſun begins to deſcend towards the ſouth pole.

Autumnal *Signs*, in aſtronomy, are the ſigns Libra, Scorpio, and Sagittarius, through which the ſun paſſes during the autumn. See Zodiac, Libra, *&c.*

Autumnal *Equinox*, the time when the ſun enters the autumnal point. See Equinox.

Autumnal *Flowers*. See Flower.

AUX, in aſtronomy, the ſame with the apogeum of the ancients, or the aphelium of the moderns. See the articles Apogeum and Aphelium.

Aux alſo denoted the arch of the ecliptic, intercepted between the firſt degree of Aries and the apogeum.

AUXILIARY, *Auxiliaris*, whatever is aiding or helping to another.

Auxiliary *Verbs*, in grammar, are ſuch as help to form or conjugate others; that is, are prefixed to them, to form or denote the moods or tenſes thereof. As *to have* and *to be*, in the Engliſh; *étre & avoir*, in the French; *ho & ſono*, in the Italian, &c.

In the Engliſh language, the auxiliary verb *am*, ſupplies the want of paſſive verbs. See Passive.

AUXILIUM, in law, the ſame with aid. See Aid.

Auxilium *Curiæ*, in law, a precept or order of court, to cite or convene one party at the ſuit of another.

Auxilium *ad filium militem faciendum, vel filiam maritandum*, a precept, or writ directed to the ſheriff of every county where the king, or other lords, had any tenants, to levy of them reaſonable aid towards the knighting his eldeſt ſon, or the marriage of his eldeſt daughter. See the article Aid.

AWARD, in law, the judgment of an abitrator, or of one who is not appointed by the law a judge, but choſen by the parties themſelves for terminating their difference. See Arbitrator.

A-WEIGH, in navigation, the anchor is called a-weigh, or a-trip, when the cable, being drawn perpendicular to it, and continued to be heaved into the ſhip, at length weighs or trips it out of the ground.

AWL, or Aul, among ſhoe-makers, an inſtrument wherewith holes are bored through the leather, to facilitate the ſtitching, or ſewing the ſame. The blade of the awl is uſually a little flat and bended, and the point ground to an acute angle.

AWME, or Aume, a Dutch liquid meaſure, containing eight ſteckans, or twenty verges or verteels, equal to the tierce in England, or to one ſixth of a ton of France.

AWN, ariſta, in botany. See Arista.

AWNING, among ſeamen, a canopy of canvas extended over the decks in hot weather, to protect them from being ſplit by the heat of the ſun; likewiſe for the convenience of the officers, &c. An awning is ſupported by a range of ſmall pillars, called ſtanchions, on each ſide of the deck, and ſuſpended in the middle by crow-feet. See the article Crowfoot.

AX, among carpenters, an inſtrument wherewith to hew wood.

This implement differs from the joiners hatchet, as being deeper and heavier.

AXILLA, in anatomy, the arm-pit, or the cavity under the upper part of the arm.

Axilla, in botany, the ſpace comprehended betwixt the ſtems of plants and their leaves.

AXILLARY, *Axillaris*, ſomething belonging to, or lying near the axilla. Thus,

Axillary *Artery* is that part of the ſubclavian branches of the aſcending trunk of the aorta, which paſſeth under the arm-pits. See Artery.

Axillary *Glands* are ſituated under the arm-pits, enveloped in fat, and lie cloſe by the axillary veſſels.

Axillary *Vein*, one of the ſubclavian veins which paſſes under the arm-pit, dividing itſelf into ſeveral branches, which are ſpread over the arm. See Vein.

AXIOM, in philoſophy, is ſuch a plain, ſelf-evident, and received notion, that it cannot be made more plain and evident by demonſtration; becauſe it is itſelf better known than any thing that can be brought to prove it: as, that nothing can act where it is not; that a thing cannot be, and not be, at the ſame time; that the whole is greater than a part thereof; and that from nothing, nothing can ariſe.

By axioms, called alſo maxims, are underſtood all common notions of the mind, whoſe evidence is ſo clear and forcible, that a man cannot deny them, without renouncing common ſenſe and natural reaſon.

The rule whereby to know an axiom, is this: Whatever propoſition expreſſes the immediate clear compariſon of two ideas without the help of a third, is an axiom. But if the truth does not appear from the immediate compariſon of two ideas, it is no axiom.

Theſe ſort of propoſitions, under the name of axioms, have, on account of their being ſelf-evident, paſſed not only for principles of ſcience, but have been ſuppoſed innate, and thought to be the foundation of all our other knowledge; though, in truth, they are no more than identic propoſitions: for to ſay that all right angles are equal to each other, is no more than ſaying, that all right angles are right angles, ſuch equality being implied in the very definition. All conſideration of theſe maxims, therefore, can add nothing to the evidence or certainty of our knowledge of them; and how little they influence the reſt of our knowledge, how far they are from being the foundation of it, as well as of the truths firſt known to the mind, Mr. Locke, and ſome others, have undeniably proved.

According to Bacon, it is impoſſible that axioms, raiſed by augmentation, ſhould be uſeful in diſcovering new works; becauſe the ſubtilty of nature far exceeds the ſubtilty of arguments: but axioms, duly and methodically drawn from particulars, will again eaſily point out new particulars, and ſo render the ſciences active.

The axioms in uſe being derived from ſlender experience, and in a few obvious particulars, are generally applied in a correſponding manner. No wonder, therefore, they lead us to few particulars; and if any inſtance, unobſerved before, happen to turn up, the axiom is preſerved by ſome trifling diſtinction, where it ought rather to be corrected.

Axiom is alſo an eſtabliſhed principle in ſome art or ſcience.

Thus it is an eſtabliſhed axiom in phyſics, that nature does nothing in vain: ſo it is in geometry, that if to equal things you add equals, the ſums will be equal. It is an axiom in optics, that the angle of incidence is equal to the angle of reflection, &c. In which ſenſe too, the general laws of motion are called axioms: whence it may be obſerved, that theſe particular axioms are but deductions from certain hypotheſes.

AXIS properly ſignifies a line, or long piece of iron or wood, paſſing through the center of a ſphere, and about which the ſphere revolves.

Axis *of the World* is an imaginary right line conceived to paſs through the center of the earth, from one pole to another, about which the ſphere of the world, according to the Ptolemaic ſyſtem, revolves in its diurnal motion.

Axis, in geometry, is that ſtraight line in a plain figure at reſt, about which the figure revolves, in order to form or generate a ſolid.

Tranſverſe Axis *of an Ellipſis*, is the longeſt axis A B (plate XIX. *fig.* 3.) drawn through the center C of the ellipſis.

Conjugate Axis *of an Ellipſis*, is the ſhorteſt axis F E, drawn through the center C, and cutting the tranſverſe axis at right angles.

Axis *of a Cone* is the ſtraight line or ſide, about which the right angled triangle forming the cone, moves; and ſo only a right cone can properly have an axis, becauſe an oblique cone cannot be generated by the motion of a plain figure about a ſtraight line at reſt: but becauſe it is plain from the definition, that the axis of a right cone is a ſtraight line, drawn from the center of its baſe to the vertex; therefore, the writers of conic ſections call likewiſe that line drawn from the center of the baſe of an oblique cone to the vertex, the axis of the cone.

Axis *of a conic Section* is a ſtraight line divided into two equal parts, and cutting all the ordinates at right angles. Thus, if AMP (plate XIX. *fig.* 4.) be drawn ſo as to cut the ordinate MN at right angles, and divide the ſection into two equal parts, then is the line AMP the axis of the ſection.

Tranſverſe Axis *of an Hyperbola* is the axis A P (plate XIX. *fig.* 5.) cutting the curves in the points A and P.

Conjugate Axis *of an Hyperbola* is the line E F, drawn through the center C, parallel to the ordinates M N, M N.

Axis *of a Cylinder* is properly that quieſcent line about which the parallelogram forming the cylinder revolves. But in both right and oblique cylinders, that right line joining the centers of the oppoſite baſes, is called the axis of the cylinder.

Axis *of a Glaſs*, in optics, is a right line, connecting the middle points of the two oppoſite ſurfaces of the glaſs.

Axis *of Incidence*, in dioptrics, is a line perpendicular to the refracting ſurface in the point of incidence, and in the medium through which the ray of incidence paſſes. Thus, if A B (plate XII. *fig.* 2.) repreſent a ray of incidence, and *abcd*, a refracting ſurface, then will F B be the axis of incidence.

Axis, in optics, is that ray which is perpendicularly on the ſurface of the eye, and conſequently paſſes through its center.

Axis *of Oſcillation* is a right line parallel to the horizon, paſſing through the center about which a pendulum vibrates.

Axis *of a Planet* is a line drawn through the center of the planet, and about which it revolves.

Axis *of a Magnet* is a right line drawn through the magnet longitudinally, and terminated by its two poles.

Axis *of a Balance* is the line about which it moves.

Axis, in anatomy, is the tooth-like eminence in the ſecond vertebra of the neck.

Spiral Axis, in architecture, is the axis of a twiſted column drawn in a ſpiral form, in order to trace the circumvolutions on the ſurface.

Axis *of the Ionic Capital* is a line paſſing perpendicularly through the middle of the eye of the volute.

Axis *in Peritrochio*, one of the five mechanical powers uſed to raiſe weights to a conſiderable height.

It conſiſts of a peritrochium, or wheel, concentric with the baſe of a cylinder, and moveable together with it about its axis.

Becauſe, in this machine, the wheel and its axis move together, it is evident that, in one turn of the wheel, when the power P (ſee plate X. *fig.* 19.) deſcends a length equal to the circumference of the wheel, the weight W will be raiſed an height equal to the circumference A, by the winding of the rope, which carries the weight upon the ſaid axis.

And becauſe, when there is an equilibrium between two weights, as W and P, there muſt be a reciprocal proportion between the maſſes and velocities; W will be to P, as the circumference of the wheel is to that of the axis (ſuppoſing the thickneſs of the rope to be inconſiderable), or as the ſemi-diameter of the wheel to the ſemi-diameter of the axis; for the ſemi-diameters of different circles are in the ſame proportion to one another as their circumferences.

The axis in peritrochio may alſo be conſidered as a lever of the firſt kind; for the fulcrum will be in the middle of the axis A. If, therefore, lines be drawn from the middle of the axis to the power and weight, parallel to the horizon, the radius or ſemi-diameter of the wheel will be the diſtance of the power, and the radius of the axis the diſtance of the weight; and when theſe radii are reciprocally as the weight and power, the machine will be in equilibrio. The wheel and axis therefore is nothing more than a perpetual lever.

It has been already obſerved that the thickneſs of the rope carrying the weight, is ſuppoſed to be inconſiderable; but as this is never the caſe in practice, when the weight is conſiderable, it will be neceſſary to make a proper allowance for it; and this is done by adding the ſemi-diameter of the rope to the ſemi-diameter of the axis; for the weight really hangs half the thickneſs of the rope beyond the axis.

It is alſo neceſſary that the line of direction in which the power acts be a tangent to the wheel; for otherwiſe it will not produce the ſame effect, as the lever to which it is applied will be ſhortened. If a plumb line be applied to any part of the circumference of the wheel above the horizontal radius, it will form a chord-line, connecting two points in the circumference of the wheel; and if this chord be biſected by a radius drawn from the center, the part of that radius intercepted between the center and the chord will be the length of the lever on which the power acts in that poſition.

The machine repreſented by the figure, is a model (made by a ſcale of an inch to a foot) of ſuch an axle and wheel, as is often made uſe of to draw water out of a well, by means of a power drawing by a rope applied to the circumference of one of the wheels of the machine, or by preſſing down ſucceſſively the handles E, F, G, H, I, K, whilſt another rope or chain is wound up upon the axis, A or B, a bucket hanging at it inſtead of the weight W. Here, in the experiment, one pound hanging at the circumference of the biggeſt wheel C D, will keep in equilibrio 12 pounds hanging at the ſmalleſt axis A, or 6 pounds at the axis B, and only 3 pounds upon the circumference T V. In the ſame manner, when the weight hanging at the axis continues in the ſame place, and to be of the ſame quantity, viz. 12 pounds; then the power which, at the circumference of the wheel C D, is equal to 1 pound, muſt be equal to $1\frac{1}{2}$ pound, if to be applied at S R; but if it be applied at one of the handles at the diſtance of a $\frac{1}{4}$ of an inch from the circumference of the wheel C D (which is the ſame as if a new wheel was added of $\frac{1}{2}$ an inch more in diameter); then a power, equal

Axis in Peritrochio

equal to no more than $\frac{1}{14}$ of a pound, will keep the weight in equilibrio; and raiſe it, if its intenſity be increaſed ever ſo little.

Axis, in natural hiſtory, an animal of the deer kind, common in ſeveral parts of Africa. It is without horns; but has a tail reaching down to its hams. The female is leſs than the male; but they are both full of red, yellow, and white ſpots, except the belly, which is entirely white.

AXUNGIA, in a general ſenſe, denotes old lard, or the drieſt and hardeſt of any fat in the bodies of animals; but, more properly, it ſignifies only hog's-lard. See the articles Fat and Lard.

Axungia *Vitri*, ſandiver, or ſalt of glaſs, a kind of ſalt which ſeparates from the glaſs while it is in fuſion.

AYEL, in law, a writ which lies where the grandfather was ſeized in his demeſne the day he died, and a ſtranger enters the ſame day, and diſpoſſeſſes the heir.

AYRY, or Aery *of Hawks*, a neſt or company of hawks, ſo called from the old French word *aire*, which ſignified the ſame.

AZAB, in the Turkiſh armies, a diſtinct body of ſoldiery, who are great rivals of the Janizaries.

AZALEA, in botany, a genus of plants, the flower of which conſiſts of a ſingle petal, divided at the ſummit into five ſegments; the fruit is a roundiſh capſule, formed of five valves, and containing as many cells: the ſeeds are numerous and roundiſh.

AZAZEL, the ſcape-goat, in Jewiſh antiquity. See Scape-Goat.

AZIMUTH, in aſtronomy, is the angle contained between the meridian and another great circle of the ſphere paſſing through the zenith and nadir; and when this vertical circle paſſes through the center of the ſun or of a ſtar, the meaſure of the angle ſo contained is ſaid to be the azimuth of the ſun or ſtar.

The word is Arabic, and ſignifies the ſame thing.

The azimuth is the complement of the eaſtern and weſtern amplitude to a quadrant.

As the method of finding the variation of the compaſs at ſea, depends entirely on having the ſun's azimuth, we ſhall here give the method of finding it, when the latitude of the place and the declination and altitude of the ſun are known.

If the latitude of the place and declination of the ſun be of one denomination, viz. both north or both ſouth, ſubtract the declination from 90 deg. but if the latitude and declination be of different denominations, viz. one north and the other ſouth, add the declination to 90 deg. then will the ſum or difference be the diſtance of the ſun from the pole, in this caſe equal to the arch S P (plate XIX. *fig.* 2.) wherein P repreſents the pole, Z the zenith, and S the place of the ſun. Now, in the ſpherical triangle S Z P, we have given S Z the complement of the obſerved altitude, Z P the complement of the latitude, and P S the polar diſtance, to find the angle S Z P the ſun's azimuth, which may be obtained by the following rule.

From half the ſum of the three ſides S Z, Z P, S P, ſubtract the ſide S P, being oppoſite to the angle ſought, and note the remainder; then ſet down the arithmetical complements of the ſides S Z, Z P, containing the angle ſought; under theſe write the ſines of the above found half ſum and remainder, then will half the ſum of theſe four logarithms be the coſine of half the required azimuth.

Example. Suppoe the latitude be 51°. 32′. north, the declination of the ſun be 21°. 57′. north, and his altitude found by obſervation be 47°. 30′. what is his azimuth?

The operation by the logarithms.

42° : 30′ Compl. altitude — — S. Co. Ar. 0.170319
38 : 28 Compl. latitude — — S. Co. Ar. 0.206168
69 30 Compl. declination
150 : 28 Sum
75 : 14 Half Sum — — — — S. — 9.985414
5 : 44 exceſs of the half ſum above *c.* dec. S.—8 999599
Sum 19. 361498
61°. 21′. — S *c* — Half Sum 9.680749

and, therefore, 61°. 21′. being doubled, gives 122°. 42′. the ſun's azimuth from the north.

The above rule is no more than a logarithmetical application of the theorem demonſtrated by Ozanem, in the third vol. of his Mathematics, pag. 124, viz. "That in "a ſpherical triangle having two unequal ſides, the "rectangle of the ſines of theſe two ſides is to the "ſquare of radius, as the rectangle of the ſine of half "the ſum of the baſe and the difference of the ſides, and "the ſine of half the difference between the baſe and "the difference of the ſame ſides, to the ſquare of the "ſine of half the vertical angle."

But in calculations relating to the higher parts of aſtronomy, it will be better to uſe this theorem; viz. $sm + ncz = b$, wherein s and c repreſent the natural ſine and coſine of the latitude of the place, m and n thoſe of the ſun's altitude, b, the coſine of the polar diſtance, and z, the coſine of the azimuth, radius equal to unity: whence we get $z = \frac{b - sm}{nc}$. The reader will find this theorem inveſtigated in Simpſon's Fluxions.

Cor. If $b = 0$, or the ſun in the equinoctial, then $z = \frac{-sm}{cn} = t^2 \times T$, where t and T are the reſpective tangents of the latitude and altitude; hence as radius (1): tangent of the latitude of the place, ſo is the tangent of the ſun's altitude to the coſine of the azimuth, reckoned from the elevated pole.

Magnetical Azimuth, an arch of the horizon, intercepted between the azimuth or vertical circle, paſſing through the center of any heavenly body and the magnetical meridian. The magnetical azimuth is found by obſerving the object with an azimuth compaſs.

Azimuth-Compass, an inſtrument for finding either the magnetical azimuth or amplitude of an heavenly object.

The learned Dr. Knight invented ſome time ſince a very accurate and uſeful ſea-compaſs, which is at preſent uſed in the navy, and will be deſcribed under the article Compass. This inſtrument, with the following contrivance added by the ingenious Mr. Smeaton, anſwers the purpoſes of an azimuth and amplitude-compaſs.

The cover of the wooden box being taken off, the compaſs is in a condition to be made uſe of in the bittacle, when the weather is moderate: but if the ſea runs high, as the inner box is hung very free upon its centers, (the better to anſwer its other purpoſes) it will be neceſſary to ſlacken the milled nut, placed upon one of the axes that ſupports the ring, and to lighten the nut on the outſide that correſponds to it. By this means, the inner box and ring will be lifted up from the edges, upon which they reſt, when free; and the friction will be increaſed, and that to any degree neceſſary, to prevent the too great vibrations, which otherwiſe would be occaſioned by the motion of the ſhip.

To make the compaſs uſeful in taking the magnetic azimuth, or amplitude of the ſun and ſtars, as alſo the bearings of headlands, ſhips, and other objects at a diſtance, the braſs edge, deſigned at firſt to ſupport the card, and throw the weight thereof as near the circumference as poſſible, is itſelf divided into degrees and halves; which may be eaſily eſtimated into ſmaller parts, if neceſſary. The diviſions are determined by means of a cat-gut line, ſtretched perpendicularly with the box, as near the braſs edge as may be, that the parallax, ariſing from a different poſition of the obſerver, may be as little as poſſible.

Underneath the card are two ſmall weights, ſliding on two wires, placed at right angles to each other; which being moved nearer to, or farther from, the center, counterbalance the dipping of the card in different latitudes, or reſtore the equilibrium of it, where it happens by any other means to be got too much out of level.

There is alſo added an index at the top of the inner box, which may be put on and taken off at pleaſure; and ſerves for all altitudes of the object. It conſiſts of a bar, equal in length to the diameter of the inner box, each end being furniſhed with a perpendicular ſtile, with a ſlit parallel to the ſides thereof; one of the ſlits is narrow, to which the eye is applied, and the other is wider, with a ſmall cat gut ſtretched up the middle of it, and from thence continued horizontally from the top of one ſtile to the top of the other. There is alſo a line drawn along the upper ſurface of the bar. Theſe four, viz. the narrow ſlit, the horizontal cat-gut thread, the perpendicular one, and the line on the bar, are in the ſame plane, which diſpoſes itſelf perpendicular to the horizon, when the inner box is at reſt, and hangs free. This index does not move round, but is always placed on, ſo as to anſwer the ſame ſide of the box.

When the ſun's azimuth is deſired, and his rays are ſtrong enough to caſt a ſhadow, turn about the wooden box, till the ſhadow of the horizontal thread, or (if the ſun be too low) till that of the perpendicular thread, in one ſtile, or the light through the ſlit in the other, falls upon the line in the index bar, or vibrates to an equal diſtance on each ſide of it, gently touching the box, if it vibrates too far: obſerve, at the ſame time, the degree marked upon the braſs edge by the cat-gut line. In counting the degree for the azimuth, or any other angle that is reckoned from the meridian, make uſe of the outward circle of figures upon the braſs edge; and the ſituation of the index bar, with regard to the card and needle, will always direct upon what quarter of the compaſs the object is placed.

But if the ſun does not ſhine out ſufficiently ſtrong, place the eye behind the narrow ſlit in one of the ſtiles, and turn the wooden box about, till ſome part of the horizontal, or perpendicular thread appears to interſect the center of the ſun, or vibrate to an equal diſtance on each ſide of it, uſing ſmoked glaſs next the eye, if the ſun's light is too ſtrong. In this method, another obſerver will be generally neceſſary, to note the degree cut by the nonius, at the ſame time the firſt gives notice that the thread appears to ſplit the object.

From what has been ſaid, the other obſervations will be eaſily performed; only, in caſe of the ſun's amplitude, take care to number the degree by the help of the inner circle of figures on the card, which are the complements of the outer to 90″; and, conſequently, ſhew the diſtance from eaſt or weſt.

The azimuth of the ſtars may alſo be obſerved by night; a proper light ſerving equally for one obſerver to ſee the thread, and the other the degree upon the card.

It may not be amiſs to remark farther, that, in caſe the inner box ſhould loſe its equilibrium, and, conſequently, the index be cut of the plane of a vertical circle, an accurate obſervation may ſtill be made, provided the ſun's ſhadow is diſtinct; for, by obſerving firſt with one end of the index towards the ſun, and then the other, a mean of the two obſervations will be the truth.

Plate XIV. *fig.* 2. is a perſpective view of the compaſs, when in order for obſervation; the point of view being the center of the card, and the diſtance of the eye two feet.

A B is the wooden box.

C and D are two milled nuts; by means whereof the axis of the inner box and ring are taken from their edges, on which they move, and the friction increaſed, when neceſſary.

E E is the ring that ſupports the inner box.

G H is the inner box; and

I is one of its axes, by which it is ſuſpended on the ring E E.

The magnet or needle appears paſſing thro' the center, together with a ſmall brace of ivory, that confines the cap to its place.

The card is a ſingle varniſhed paper, reaching as far as the outer circle of figures, which is a circle of thin braſs; the edge whereof is turned down at right angles to the plane of the card, to make it more ſtiff.

O is a cat-gut line, drawn down the inſide of the box, for determining the degree upon the braſs edge.

PQRS is the index bar, with its two ſtiles and cat-gut threads; which being taken off from the top of the box, is placed in two pieces, T and V, notched properly to receive it.

W is a place cut out in the wood, ſerving as an handle.

AZIMUTH *Circles*, called alſo azimuths, or vertical circles, are great circles of the ſphere interſecting each other in the zenith and nadir, and cutting the horizon at right angles.

Theſe azimuths are repreſented by the rhumbs on common ſea-charts, and on the globe they are repreſented by the quadrant of altitude, when ſcrewed in the zenith. On theſe azimuths is reckoned the height of the ſtars and of the ſun, when not in the meridian.

AZOGA SHIPS, are thoſe Spaniſh ſhips commonly called the quickſilver ſhips, from their carrying quickſilver to the Spaniſh Weſt Indies, in order to extract the ſilver out of the mines of Mexico and Peru. Theſe ſhips, ſtrictly ſpeaking, are not to carry any goods unleſs for the king of Spain's account.

AZONI, *αζωνοι*, in ancient mythology, a name applied by the Greeks to ſuch of the gods as were deities at large, not appropriated to the worſhip of any particular town or country, but acknowledged in general by all countries, and worſhipped by every nation. Theſe the Latins called *dii communes*. Of this ſort were the Sun, Mars, Luna, &c.

AZOTH, in ancient chemiſtry, the firſt matter of metals, or the mercury of a metal; more particularly that which they call the mercury of philoſophers, which they pretend to draw from all ſorts of metallic bodies.

The azoth of Paracelſus, which he boaſted of as an univerſal remedy, is pretended to be a preparation of gold, ſilver, and mercury.

AZURE, in a general ſenſe, the blue colour of the ſky. See SKY and BLUE.

AZURE, among painters, the beautiful blue colour, with a greeniſh caſt, prepared from the lapis lazuli, generally called ultramarine.

With greater propriety, however, azure ſignifies that bright blue colour prepared from the lapis armenus, a different ſtone from the lapis lazuli, though frequently confounded together. This colour is, by our painters, commonly called Lambert's blue.

AZURE, in heraldry, the blue colour in the arms of any perſon below the rank of a baron. In the eſcutcheon of a nobleman, it is called ſaphire; and in that of a ſovereign prince, Jupiter. In engraving, this colour is expreſſed by lines, or ſtrokes drawn horizontally.

AZURIUM, the name of a chemical preparation from two parts of mercury, one of ſulphur, and a fourth of ſal ammoniac, mixed in a mortar, put into a glaſs veſſel, and ſet over the fire till a bluiſh ſmoak ariſes, &c.

AZYGOS, in anatomy, a vein riſing within the thorax on the right ſide, having no fellow on the left; whence it is called azygos, or vena ſine pari.

It is extended through the right ſide of the cavity of the thorax, and being deſcended to the eighth or ninth vertebra, it then begins to keep the middle, and ſends forth on each ſide intercoſtal branches to the interſtices of the eight loweſt ribs; being then divided into two branches, of which the larger deſcends to the left, betwixt the proceſſes of the diaphragm, and is inſerted ſometimes into the cava, above or below the emulgent, but oftener joined to the emulgent itſelf. The other, which goes down on the right ſide, enters the cava, commonly a little above the emulgent, but is very ſeldom joined to the emulgent itſelf.

AZYMITES, azymitæ, in church-hiſtory, Chriſtians who adminiſter the euchariſt with unleavened bread.

The word is formed from the Greek, *α*, priv. and *ζυμη*, ferment.

This appellation is given to the Latin by the Greek church, becauſe the members of the former uſe fermented bread in the celebration of the euchariſt. They alſo call the Armenians and Maronites by the ſame name, and for the ſame reaſon.

AZYMOUS, ſomething unfermented, or made without leaven; as unleavened bread. Sea-biſket is of this kind; and therefore, according to Galen, leſs wholeſome than bread that has been fermented.

B.

B The ſecond letter of the Engliſh and moſt other alphabets, ancient and modern, except the old Iriſh, where it is the firſt, and the Abyſſinian, in which it is the ninth.

B, among the ancients, was a numeral letter, and with the Hebrews and Greeks denoted 2; but with the Romans 300, and with a daſh over it 3000.

B.A. ſignifies batchelor of arts, B.L. batchelor of laws, and B.D. batchelor of divinity.

BAAL, or Bel, an Hebrew and Chaldaic word, which ſignifies lord, or mighty. It was the name of the idol of the Moabites and Phœnicians, and moſt of the nations that bordered upon the Jews. Perhaps the idolators pretended to adore the true God under the name and figure of Baalim. The Grecians, who were accuſtomed to take the eaſtern divinities for their own, called this idol Jupiter, and ſometimes Mars; but the Babylonians underſtood by it either the ſtars and hoſt of heaven, or ſuch kings and heroes whoſe memory they had conſecrated to poſterity by a religious worſhip. The Phœnicians adored the ſun under the names of Baal and Moloch. It is thought this idol was the firſt invented by ſuperſtition, and the original worſhip of idolatry. *Selden de Diis Syriis.*

BABBLING, among ſportſmen, is ſaid of hounds which are too buſy after they have found a good ſcent.

BABOON, in natural hiſtory, a large kind of ape, common in the Eaſt and Weſt Indies. The head is large, and the mouth furniſhed in a particular manner with whiſkers; the face is naked, but the back part of the head hairy. It has a very ſhort tail, and is of a dark olive-colour.

BABYLONISH, or Babylonian, ſomething belonging or peculiar to Babylon. Thus we meet with Babyloniſh epocha, hours, &c. See Epocha, Hour, &c.

BACCHANALIA, feaſts celebrated in honour of Bacchus, by the ancient Greeks and Romans.

Two of theſe feaſts were particularly remarkable, and diſtinguiſhed by the epithets *greater* and *leſſer*. The latter were held in the open fields during the autumn; but the former were celebrated in the city about the vernal equinox.

Both theſe feaſts were accompanied with games, ſpectacles, and theatrical repreſentations; and it was alſo at theſe feſtivals that the poets contended for the prize of poetry. Some of thoſe who were initiated into the Bacchanalia repreſented Silenus; others Pan; others Satyrs; and in this manner appeared in public day and night, counterfeiting drunkenneſs, dancing obſcenely, committing all kinds of licentiouſneſs and debauchery, and running over the mountains and through the foreſts, with horrible ſhrieks and howlings, crying out Ευοι Βακχε, or Ιω Βακχε.

Livy informs us, that, during the Bacchanalian feaſts at Rome, ſuch ſhocking diſorders were practiſed under the cover of the night, and which thoſe who were initiated were bound by the moſt horrid oaths to conceal, that the ſenate was obliged to interpoſe their authority, by ſuppreſſing them firſt at Rome, and afterwards throughout all Italy.

BACCHIUS, in ancient poetry, a kind of foot compoſed of two long and a ſhort ſyllable, as the word *ăvārī*. It has its name from the god Bacchus, becauſe it frequently occurred in the hymns compoſed in honour of that deity.

BACCHUS, in mythology, a pagan deity, the inventor or god of wine. He is feigned to have been the ſon of Jupiter and Semele; and is ſaid to have been the firſt that yoked oxen to the plough.

BACCIFEROUS *Plants*, in botany, are ſuch as bear berries, or fruit covered with a thin membrane, wherein is contained a pulp, which grows ſoft and moiſt, when ripe, and incloſes the ſeed within its ſubſtance.

The word is Latin, and compounded of *bacca*, a berry, and *fero*, to bear.

Mr. Ray divides bacciferous trees into four kinds. 1. Such as bear a calicute, or naked berry; the flower and calix both falling off together, and leaving the berry bare; as the ſaſſafras trees, &c.

2. Such as have a naked but polypyreneous fruit; that is, containing two or more kernels or ſeeds within it; as the jaſminum, liguſtrum, &c.

3. Such as have a naked but polypyreneous fruit; that is, containing in it only one ſeed; as the arbutus, terebinthus, lentiſcus, &c.

4. Such as have their fruit compoſed of many acini, or round ſoft balls, ſet cloſe together like a bunch of grapes; as the ava marina, rubus vulgaris, rubus idæus, and the rubus minor fructu cæruleo.

BACHELOR, or Batchelor. See Batchelor.

BACK, in anatomy; ſee Dorsum.

Back-Astern, in rowing, is to row a boat or veſſel with her ſtern, or hinder-part, foremoſt, contrary to her uſual motion.

Back-Board *of a Boat*, a board ſtretching acroſs the hinder-part of any boat, behind the ſeats, for the paſſengers to lean againſt.

BACKING *the Sails*, in navigation, to arrange them in a ſituation that will force the ſhip to retreat, or move backwards: this is, however, only done in narrow channels, when a ſhip is carried along ſideways by the tide or current, and wants to avoid any thing that may interrupt her progreſs, as ſhoals, veſſels at anchor, &c. or in the line of battle, when a ſhip wants to be immediately oppoſite to another with which ſhe is engaged. See Fill, Shiver, and Veer.

Back-Bone. See Vertebra.

Back-Painting, the method of painting mezzotinto prints, paſted on glaſs, with oil-colours.

The art conſiſts chiefly in laying the print upon a piece of crown glaſs, of ſuch a ſize as fits the print.

In order to do this, take your print, and lay it in clean water for two days and two nights, if the print be on very ſtrong, cloſe, and hard gummed paper; but if upon an open, ſoft, ſpungy paper, two hours will ſometime ſuffice, or more, according as the paper is.

The paper or picture having been ſufficiently ſoaked, take it out and lay it upon two ſheets of paper, and cover it with two more; and let it lie there a little to ſuck out the moiſture.

In the mean time, take the glaſs the picture is to be put upon, and ſet it near the fire to warm; take Straſburg turpentine, warm it over the fire till it is grown fluid; then with a hog's-hair bruſh ſpread the turpentine very ſmoothly and evenly on the glaſs.

When this has been done, take the mezzotinto print from between the papers, and lay upon the glaſs; beginning firſt at one end, rubbing it down gently as you go on, till it lie cloſe, and there be no wind bladders between.

Then, with your fingers, rub or roll off the paper from the back-ſide of the print, till it looks black, i. e. till you can ſee nothing but the print, like a thin film, left upon the glaſs, and ſet it by to dry.

When it is dry, varniſh it over with ſome white tranſparent varniſh, that the print may be ſeen through it, and then it is fit for painting.

The utmoſt care will be neceſſary in rubbing or rolling the paper off the print, ſo as not to tear it, eſpecially in the light parts.

You may, inſtead of ſoaking your prints two days and two nights, roll them up and boil them for about two hours, more or leſs, according to the quality of the paper, in water, and that will render it as fit for rubbing, rolling, or peeling, as the other way.

This being done, and your oil colours prepared, ground very fine, and tempered up very ſtiff, lay on the back ſide of the tranſparent prints, ſuch colours as each particular part requires; letting the maſter-lines of the print ſtill guide your pencil, and ſo each particular colour will lie fair to the eye on the other ſide of the glaſs, and look almoſt as well as a painted piece, if it be done neatly.

The ſhadows of the print are generally ſufficient for the ſhadow of every colour; but if you have a mind to give a ſhadow by your pencil, then let the ſhadows be laid on firſt, and the other colours afterward.

In laying on colours in this kind of back painting, you need not be curious as to the laying them on ſmooth. This is not at all requiſite here, where the chief aim is only to have the colours appear well on the fore ſide of the print; and therefore the only care to be uſed in this work, is to lay the colours on thick enough, that its body may ſtrike the colour of it plainly through the glaſs.

BACK-STAFF, a name formerly given to a ſea-quadrant invented by Capt. Davis; becauſe the back of the artiſt is turned towards the ſun at the time of obſervation. See *Davis's* QUADRANT.

BACK-STAYS, in naval affairs, ropes faſtened to the top-maſt-heads, and reaching down behind the maſt to the outſide of the ſhip, where they are drawn extremely tight: two of them are generally formed of one rope; the middle of which is fixed on the maſt-head: their uſe is to ſuſtain the top-maſts, and keep them upright when they are preſſed with a weight of ſail, againſt which they act with a counter-force. See LANIARD, STAY, and TOP-MAST.

BACON's *philoſophy*, the philoſophy propoſed and recommended by lord Bacon.

That great genius was born in the year 1560, and gave marks in his youth of what his manhood would produce. Queen Elizabeth was an admirer of his remarkable ſagacity. He ſtudied the Ariſtotelian philoſophy at Cambridge; and, before he was ſixteen years of age, diſcovered the abſurdity of that jargon in vogue at that time. He afterwards applied himſelf to the ſtudy of the law; and his merit raiſed him to the dignity of lord Chancellor, under king James I. He was accuſed of bribery; and the king refuſing him protection, was fined by the houſe of lords, ſtripped of his chancellorſhip, and caſt into priſon. He was ſoon after reinſtated in his honours and fortunes; but what he had undergone, gave him a diſlike to buſineſs, and increaſed his paſſion for ſtudy. At laſt he died aged 66 years, poor, and in very mean circumſtances.

No man has contributed more to the advancement of learning than lord-chancellor Bacon: he ſaw the imperfection of the philoſophy of the ſchools, and taught the only way to amend it. This great man, indeed, did not know nature: but he knew and pointed out all the ways that lead to her. He entertained an early contempt for what the univerſities called philoſophy; and did every thing in his power to prevent ſocieties, inſtituted for the improvement of human reaſon, from continuing to ſpoil it by a heap of impertinent terms, ſubſtantial forms, &c. which not only had made ignorance to be reverenced, but was, by a ridiculous mixture with religion, rendered ſacred.

He compoſed two works with a deſign to improve the ſciences, and carry them to perfection. In the firſt, intitled *de Augmentis Scientiarum*, he ſhews the ſtate of learning, and points out a method of carrying it to greater perfection; but adds, that we muſt never hope to carry our diſcoveries to any great length, unleſs other methods were purſued than thoſe then in uſe. He ſhews that the logic then taught in the ſchools, was fitter for wrangling than to direct the mind in its ſearch after truth. Ariſtotle, ſays he, from whom we have this art, has proceeded on wrong principles; he has made his phyſics conformable to his logic, inſtead of making his logic conformable to his phyſics; and thus overturning the order of nature, has ſubjected the end to the means.

To correct the faults in the common logic, Bacon compoſed a ſecond work, intitled *Organum Scientiarum*, wherein he has taught a new logic, the principal end of which is to ſhew how to make a good induction, as the end of Ariſtotle is how to make a good ſyllogiſm. Bacon looked on this as his maſter-piece, and ſpent eighteen years in compoſing it.

Nor was the cauſe of our errors hid from this great man; he ſaw that our ideas were operations of the mind; and that, in order to diſcover truth, they muſt be directed in a new method.

This advice he frequently repeats in the work juſt mentioned. But who, in an age ſo prejudiced in favour of the jargon of the ſchools, and the notions of innate ideas, liſtened to his doctrine? Who did not look on his new method of improving the human underſtanding, as a chimerical project? The method Bacon propoſed was too perfect to be accepted at once: errors of long ſtanding maintain their poſt with ſome obſtinacy; and the Carteſian philoſophy was embraced, becauſe it admitted ſome of the former errors. Beſides, lord Bacon's employments took up much of his time, and prevented him from carrying into execution himſelf the advice he gave to others: whereas Deſcartes gave himſelf up entirely to philoſophy; and, being a man of a very lively and fruitful imagination, has ſubſtituted in the room of the errors of the ſchools, others of a more ſeducing nature.

Lord Bacon's attention to the ſciences in general did not hinder him from applying himſelf to ſome in particular; and as he thought natural philoſophy the baſis of all the other ſciences, he principally applied himſelf to bring that to ſome degree of perfection: but in this he acted like ſome great architects, who, ſcorning to work after others, begin with pulling every thing down, and raiſe their building on a plan entirely new. He, like theſe, never thought once about embelliſhing or repairing what had been already begun by others; but propoſed to eſtabliſh a new ſyſtem of phyſics, without making any uſe of what had been left us by the ancients, whoſe principles he ſuſpected. To accompliſh this great deſign, he reſolved to publiſh a phyſical treatiſe every month; and began with one upon the Winds: he afterwards publiſhed one on Heat; another on Motion; and, at laſt, one on Life and Death. But as it was impoſſible for a ſingle man to give a complete ſyſtem of phyſics in general, with equal exactneſs, after having given directions to ſerve as a rule for thoſe who were deſirous of proceeding on his principles, he contented himſelf with drawing the out-lines of four other treatiſes, and furniſhed materials for them, in a work, intitled *Sylva Sylvarum*, wherein he has collected a vaſt number of experiments, to ſerve as a foundation for his new phyſics. In ſhort, before lord Bacon, nobody knew any thing of natural philoſophy; and all the experiments made ſince his time, ſeem to have been pointed out by this great genius.

His moral eſſays are much eſteemed; but they are wrote rather to inſtruct than entertain: an eaſy genius, a ſound judgment, the ſenſible philoſopher, and man of reflection, ſhine in theſe eſſays by turns. This was one of the fruits of the retreat of a man who had quitted the world, after having long ſupported a great ſhare in its proſperity and adverſity. There are alſo ſome very fine things in his book concerning the wiſdom of the ancients, wherein he has moralized the fables which compoſe the mythology of the Greeks and Romans.

He wrote, beſides, the Hiſtory of Henry VII. in which notwithſtanding there are ſome traces of the bad taſte of his age, yet it abounds in judicious remarks, and ſhews he was a refined politician, as well as a great philoſopher.

BACULÆ, in fortification, a kind of portcullis, or gate, made like a pitfall, with a counterpoiſe, and ſupported by two ſtrong ſtakes. It is uſually erected before the corps de garde, not far from the gate of a place.

BACULOMETRY, the art of meaſuring acceſſible or inacceſſible heights, by the help of ſtaves.

The word is formed from the Latin, *baculus*, a ſtaff; and the Greek, μετρεω, to meaſure.

BADGE, in naval architecture, an ornament placed on the quarter of ſmall ſhips, very near the ſtern, containing either a window for the convenience of the cabbin, or the repreſentation of it: it is commonly decorated with marine figures, martial inſtruments, &c. See QUARTER, and STERN.

BADGER, *Taxus*, or *Meles*, in natural hiſtory, the name of an animal very common in many parts of England.

It has a thick ſhortiſh body, with a very ſhort neck, and coarſe hair, nearly reſembling that of a hog. On the back it is of a paliſh yellow at the roots, in the middle brown or black, and yellow at the ends; inſomuch, that at firſt ſight the creature appears to be of a blackiſh grey. On the ſides and under the belly the hair is entirely of a pale yellow; and on the ſhoulders, legs, as well before as behind, and under the throat, he is quite black. From the top of the head there is a white line or ſtripe two inches broad; and below it, on each ſide the noſtrils, about the eyes, and farther than the ears, there is a black ſpace or ſtripe in the ſhape of a pyramid; and below that again, on both jaws, the hair is white, which render the whole head of a pied colour.

The tail is ſhort and thick, beſet with ſtrong longiſh hair, and the ears are ſhort, roundiſh, and reſemble thoſe of a rat. The eyes are ſmall in proportion to the body, and the muzzle is like that of a dog. The tongue is of a middle ſize, the legs ſhort, and the teeth like thoſe of a dog. The fore-feet are armed with very long claws, with which it makes holes in the earth; and the head is in ſhape nearly like that of a fox, for from a broad baſe, it ends in a ſharp muzzle, which renders it almoſt of a triangular figure. The jaws, or cheeks, are full and tumid, on account of the thickneſs of the muſcles; for which reaſon this creature bites very hard.

He lives upon beetles and other inſects; for in his ſtomach, which is very large, great numbers of theſe have been found, mixed with the roots of graſs. Some ſay he feeds upon apples and grapes; and that he is fond of rabbits, geeſe, fowls, and other birds; but, of this, little can be ſaid with any certainty. He has none of the groſs inteſtines; nor no blind gut, at leaſt none could be found; but the kidneys are pretty large. The greateſt peculiarity is a large orifice directly under the tail, above the paſſage for the excrements: it is a ſort of a bag, or purſe, which is hairy within, and full of a white ſubſtance of a thick conſiſtence. Sometimes it is very ſmall in quantity; and has no ſenſible ſmell. The external part of this purſe is covered with conglomerate glands on all ſides. Beſides this cavity, there are two larger glands near the anus, which are hollow within, and full of a ſort of fat of a ſtrong ſmell, which empty themſelves by two holes into the gut. The gall-bladder is long; and there are three biliary ducts which belong to three diſtinct veſſels; that is, there are three biliary paſſages that concur with the cyſtic duct.

The burrows that he makes in the earth are not only for his own ſafety, but for the ſake of getting his food; for he finds a great many inſects under the earth, as well as the roots of plants. The parts of England in which he chiefly abounds at preſent, are Eſſex, Suſſex, and ſome of the midland counties.

The fleſh of a badger is ſaid to be good eating, and to taſte like that of a boar. The fat is emollient, warm, and penetrating; and it is thought to be good to eaſe pains in fits of the gravel.

White BADGER, an animal ſometimes ſeen in New-York; from the tip of the noſe to the end of the tail is a foot and nine inches in length. The eyes are ſmall in proportion to the ſize, and the ears ſhort; the legs are alſo very ſhort with white claws. The whole body is covered with very thick hair, which is white on the back, and of a whitiſh yellow on the lower parts.

The badger of Surinam is about a foot and a half long, with ſhort ears, a roundiſh head, longiſh muzzle, and ſhort legs. The claws are black, long, and crooked; and the whole body, except the belly which is yellow, is covered with hair of a deep cheſnut colour, inclining to black; but the fore part of the head is not of ſo deep a colour; and the tail, which is as long as the body, is brown, and as it were ſtriped with yellow.

BADGER, in old law books, a perſon licenſed to purchaſe corn at one place, and ſell it at another, without incurring the penalty of an engroſſer.

BADIANE, or BADIAN, the ſeed of a tree growing in China. It has the ſmell of aniſeed; and is uſed by the Chineſe to give their tea an aromatic taſte.

BÆTYLIA, anointed ſtones, worſhipped by the Phœnicians. They were commonly of a black colour, and conſecrated to ſome god, as Saturn, Jupiter, the Sun, &c.

The memory of Jacob's ſetting up the ſtone he had uſed for a pillow, pouring oil on the top of it, and calling the place Bethel, ſeems to have been preſerved under the bætulia, or anointed ſtones, of the Phœnicians. Damaſcius, a pagan writer in the time of Juſtinian, tells us, that he had ſeen on Mount Libanus, near Heliopolis in Syria, ſeveral of theſe ſtones, of which many wonderful things were reported.

BAFFETAS, or BAFTAS, a cloth made in the Eaſt-Indies, from coarſe white cotton thread. Thoſe of Surat are reckoned the beſt. They are from thirteen French ells and three quarters to fourteen long, and ſeven eighths broad. There are alſo ſome which meaſure but five ſixths of an ell, or even but half of an ell in breadth. Theſe narrow baffetas are called Orgagis, Gaudivis, Nerindes, and Labouis, according to the names of the places where manufactured.

There are alſo narrow white baffetas, which meaſure thirteen ells and a half in length, by half an ell in breadth. Broad white baffetas, fourteen ells, by three quarters.

Broad-brown and narrow-brown baffetas are made of raw thread; that is, thread before it has been bleached. The former are fourteen ells long, by half an ell broad; the latter of the ſame length, and three quarters in breadth.

BAG, in commerce, a term ſignifying a certain quantity of ſome particular commodity; as a bag of almonds, for inſtance, is about three hundred weight; of aniſeſeeds, from three to four hundred, &c.

Bags are uſed, in moſt countries, to put ſeveral ſorts of corn in, either of gold, ſilver, braſs, or copper. Bankers, and others, who deal much in current caſh, label their bags of money, by tying a ticket or note at the mouth of the bag, ſignifying the coin therein contained, the ſum total, its weight, and of whom it was received. Tare is allowed for the bag.

BAG, among farriers, is when, in order to retrieve a horſe's loſt appetite, they put an ounce of aſſa-fœtida, and as much powder of ſavin, into a bag, to be tied to the bit, keeping him bridled for two hours, ſeveral times a day: as ſoon as the bag is taken off, he will immediately eat. The ſame bag will ſerve a long time.

BAGGAGE is particularly uſed, in the military art, for the neceſſaries, utenſils, apparel, &c. of the officers and ſoldiers.

The baggage includes alſo women, children, ſuttlers, &c. The baggage-waggons before a march are appointed a rendezvous, where they are marſhalled by the waggon-maſter general, according to the rank the ſeveral regiments bear in the army. On a march, they are ſometimes ordered to follow the reſpective columns of the army, ſometimes to follow the march of the artillery, and ſometimes to make a column of themſelves. The general's baggage is commonly firſt. If the army march from the right, the baggage of that wing has the van; if from the left, the baggage of the left has the van. Each waggon has a diſtinguiſhing flag, to ſhew to what regiment it belongs. *Guillet.*

BAGNIO, an Italian word, ſignifying a bath: we uſe it for a houſe with conveniences for bathing, cupping, ſweating, and otherwiſe cleanſing the body; and ſometimes for worſe purpoſes.

BAGNIO is, in Turky, become a general name for the priſons where their ſlaves are incloſed, it being uſual in theſe priſons to have baths.

BAGNOLIANS, *Bagnolenſes*, in church-hiſtory, a ſect of heretics, who in reality were Manichees, though they ſomewhat diſguiſed their errors. They rejected the Old Teſtament, and part of the New; held the world to be eternal, and affirmed that God did not create the ſoul when he infuſed it into the body.

BAGPIPE, a muſical inſtrument of the wind kind, chiefly uſed in country places, eſpecially in the north: it conſiſts of two principal parts; the firſt a leathern bag, which blows up like a foot-ball, by means of a port-vent, or little tube, fitted to it, and ſtopped by a valve: the other part conſiſts of three pipes or flutes; the firſt called the great pipe, or drone; and the ſecond, the little one; which paſs the wind out only at the bottom: the third has a reed, and is played on by compreſſing the bag under the arm, when full, and opening or ſtopping the holes, which are eight, with the fingers. The little pipe is ordinarily a foot long; that played on, thirteen inches; and the port-vent ſix.

BAHAR, or BARR, a weight uſed in Ternate, Mocha, in the Moluccas, Achem, and divers other parts of the Eaſt-Indies.

There are two kinds: the great, wherewith ſpice is weighed, equivalent to 200 catis, at 26 taels to the cati, amounting to 481 pounds 4 ounces, Paris meaſure.

The little bahar ſerves for the weighing quickſilver, vermillion, ivory, ſilk, muſk, and other precious wares, containing likewiſe 200 catis, but at 22 taels to the cati, amounting to about 401 pounds ſeven ounces, Paris meaſure. The Chineſe Bahar is 300 catis, but each cati only equal to 16 taels.

BAHIR, a Hebrew term ſignifying famous or illuſtrious; but particularly uſed for a book of the Jews, treating of the profound myſteries of the cabala, being the moſt ancient of their rabbinical works.

BAIL, in law, the ſetting at liberty one arreſted, or impriſoned, upon an action, either civil or criminal, upon ſureties taken for his appearance at a day and place aſſigned; and is either common or ſpecial.

Common bail is in actions of ſmall prejudice, or ſlight proof, in which caſe any ſureties are taken.

Special bail is that given in caſes of greater moment, where it is required that the ſureties be ſubſidy-men at leaſt, and according to the matter in queſtion.

It was ſome years ago enacted, that no perſon ſhould be held to ſpecial bail in any action brought for leſs than ten pounds: but this is only obſerved as to writs iſſued out of the courts of Weſtminſter-Hall; for the marſhal's court continues to arreſt and hold to ſpecial bail in actions exceeding forty ſhillings.

By the indulgence of the common-law, all perſons might be bailed till they were convicted of the offence laid to their charge: but it is enacted, by ſtatute, that murderers, outlaws, houſe-burners, thieves, openly defamed, ſhall not be bailed. However, this ſtatute does not extend to the court of the king's-bench, which bails in all caſes whatſoever, and may bail even for murder, &c.

Clerk of the BAILS is an officer belonging to the court of the king's-bench: he files the bail-pieces taken in that court, and attends for that purpoſe.

BAILE, or BALE, in the ſea language. The ſeamen call throwing the water by hand, out of the ſhip or boat's hold, bailing. They alſo call thoſe hoops that bear up the tilt of a boat, its bails.

BAILEMENT, in law, the delivery of things, whether writings or goods, to another, ſometimes to be delivered back to the bailer; that is, to him who ſo delivers them; ſometimes to the uſe of him to whom they are delivered; and ſometimes to a third perſon.

BAILIFF, an officer appointed for the adminiſtration of juſtice within a certain diſtrict, called a bailiwick.

BAILIFFS *Errant*, ſuch as are appointed by the ſheriff to go up and down the county, to ſerve writs and warrants, ſummon county-courts, ſeſſions, aſſizes, and the like.

BAILIFFS *of Franchiſes*, thoſe appointed by every lord within his liberty, to do ſuch offices therein, as the bailiff errant does at large in the county.

There are alſo bailiffs of foreſts, and bailiffs of manors, who direct huſbandry, fell trees, gather rents, pay quit-rents, &c.

BAILIWICK, that liberty which is exempted from the ſheriff of the county, over which liberty the lord thereof appoints his own bailiff, with the like power within his precinct, as an under-ſheriff exerciſes under the ſheriff of the county: or it ſignifies the precinct of a bailiff, or the place within which his juriſdiction is terminated.

BAIOCAO, a copper coin, current at Rome, and throughout the whole ſtate of the church, ten of which make a julio, and an hundred a Roman crown.

BAIRAM, in the Mahometan cuſtoms, a yearly feſtival of the Turks, which they keep after the faſt of Ramazan.

The Mahometans have two bairams, the great and the little.

The little bairam holds for three days, and is ſeventy days after the firſt, which follows immediately the Ramazan. During the bairam the people leave their work for three days, make preſents to one another, and ſpend the time with great manifeſtations of joy. If the day after Ramazan ſhould prove ſo cloudy as to prevent the ſight of the new moon, the bairam is put off to the next day, when it is kept, even if the moon ſhould ſtill be obſcured. When they celebrate this feaſt, after numerous ceremonies, or rather ſtrange mimicries, in their moſque, it is concluded with a ſolemn prayer againſt the infidels, to extirpate Chriſtian princes, or to arm them againſt one another, that they may have an opportunity to extend the borders of their law.

BAIT, among fiſhermen, implies a ſubſtance proper to be faſtened to a hook, in order to catch the different ſorts of fiſh.

Baits are of two ſorts. 1. The natural ones, or thoſe generally living, as maggots, bobs, frogs, &c. 2. Of the ſecond kind are all artificial baits, whether ſuch as imitate the living baits, or paſtes of ſeveral compoſitions and figures.

Sheep's blood and cheeſe are good baits in April; the bobs dried, waſps, and bees, are for May; brown flies for June; maggots and hornets for July; ſnails in Auguſt; graſhoppers in September; corn and bramble berries at the fall of the leaf: the red-earth worm is good for ſmall fiſh all the year round; and ſmall fiſh are good baits for pikes at all times.

There are ſeveral artificial baits for intoxicating of fowls, and yet without tainting or hurting their fleſh: for the greater ſort of land-fowls, the bait may be made thus: Take a peck, or a leſſer quantity, of wheat rye, &c. with which mix two handfuls of nux vomica; boil them together till they are almoſt ready to burſt; ſtrew them upon the land where you deſign to take the fowl, and ſuch as eat thereof will be intoxicated, and lie as if dead. Small birds may be taken with only this alteration; inſtead of wheat, or the like grain, take hemp-ſeed, &c.

BAKING, the art of preparing bread, or of reducing meal of any kind, whether ſimple or compound, into bread. See BREAD, BISKIT, &c.

BAKING *of Porcelain*, or *China Ware*. See CHINA *Ware*.

BALANCE, or BALLANCE, *Libra*, one of the ſix ſimple powers in mechanics, principally uſed in determining the equality or difference of weights in heavy bodies, and conſequently their maſſes or quantities of matter.

The ballance is of two kinds, the ancient and the modern.

The ancient, or Roman, called alſo the ſtatera Romana, or ſteel-yard, conſiſts of a lever or beam, moveable on a center, and ſuſpended near one of its extremities: the bodies to be weighed are applied on one ſide of the center, and their weight is ſhewn by the diviſion marked on the beam, where the weight, which is moveable along the lever, keeps the ſteel-yard in equilibrio. This balance is ſtill frequently uſed in weighing heavy bodies.

The modern balance now generally uſed conſiſts of a lever or beam ſuſpended exactly in the middle, having ſcales or baſons hung to each extremity.

The lever is called the jugum or beam, and the two moieties thereof on each ſide the axis, the brachia or arms. The line on which the beam turns, or which divides its brachia, is called the axis; and when conſidered with regard to the length of the brachia, is eſteemed a point only, and called the center of the balance: the handle whereby it is held, or by which the whole apparatus is ſuſpended, is called trutina; and the ſlender part perpendicular to the beam, whereby either the equilibrium, or preponderancy of bodies is indicated, is called the tongue of the balance. Thus, in *fig.* 14. Plate XV. *a b*, is the beam, divided into two equal brachia or arms by the white ſpot in the center, which is the axis or center of the balance, and *c*, is the tongue. The trutina, on which the axis is ſuſpended, is not repreſented in this figure, in order to render the other parts more conſpicuous.

It follows, from what has been obſerved therefore, that in the Roman balance, the weight uſed for a counterpoiſe is the ſame, but the points of application varies: in the common balance the counterpoiſe is various, and the point of application the ſame. The principle on which each is founded, may be very eaſily underſtood from the following obſervations, and the general properties of the lever. See LEVER.

The beam A B (plate XIX. *fig.* 8.) is a lever of the firſt kind; but inſtead of reſting on a fulcrum, is ſuſpended by ſomething faſtened to C, its center of motion: conſequently the mechaniſm of the balance depends on the ſame theorems as the lever.

Hence, as the quantity of matter in known weight is to its diſtance from the center of motion; ſo is the diſtance of the unknown weight to its quantity of matter.

Or, becauſe when the balance moves about its center, the point B deſcribes the arch B *b*, while the point A deſcribes the arch A *a*; but theſe arches are to each other as their radii A C, B C; that is, as the velocities of the weight and power. If therefore the body ſuſpended at B, multiplied by its velocity, be equal to the body ſuſpended at A, multiplied by its velocity; or $B \times BC = A \times AC$, the balance will be in equilibrio.

Hence the nature and uſe of the ſteel-yard is eaſily known. Let A B (plate XIX. *fig.* 7.) repreſent an inſtrument of this kind; *b*, the trutina, or handle on which the beam turns; *k*, a ring on which the balance may be ſuſpended on a nail, or hook; *f*, the hook on which the body is to be weighed is hung; *e*, a collar or guard by which the hook *f* is faſtened to the beam; *g*, a moveable collar; *h*, a ſwivel; *i*, the counterpoiſe. From what has been ſaid, it evidently follows, that if the body to be weighed be faſtened to the hook *f*, and the whole ſuſpended by the ring *k*, the diviſion on which the counterpoiſe is placed to maintain an equilibrium in the balance, will ſhew the weight of the body required; provided the weight of the counterpoiſe *i* be known, and the large diviſions 1, 2, 3, &c. be each equal to the diſtance between the center of the balance and the ſcrew which faſtens the guard *c*, to the ſhorter arm of the balance. It will alſo be neceſſary that the ſteel-yard itſelf, with its whole apparatus, excluſive of the counterpoiſe, be in equilibrio, when ſuſpended on the ring *k*. If the body to be weighed be heavier than the diviſions on the longer arm will indicate, the balance is turned the lower ſide upwards, and ſuſpended on the ring *l*, by which means the diviſions become ſhorter, becauſe the diſtance between that trutina *d*, and the ſcrew on which the guard *c* moves, is leſs: the diviſions in the figure on this ſide extending to 17, whereas they extend only to ſix on the other. It will be unneceſſary perhaps to obſerve, that the ſame precaution, with regard to the center of gravity when the balance is ſuſpended, is alſo neceſſary when this ſide of the balance is uſed, as we before mentioned with regard to the other.

We have already obſerved, that in the common ſcales, the two brachia or arms of the balance, *e f*, *e g*, (plate XIX. *fig.* 6.) are equal to each other, and conſequently equal weights placed in the ſcales *d*, *d*, will be in equilibrio, when the balance is ſuſpended on its center *e*, as in the figure, where the ring at the extremity of the trutina *b*, is hung on the tapering rod *a*, *b*, fixed in the foot or baſis *c*.

The deceitful BALANCE, or that which cheats by the inequality of its brachia, is founded on the ſame principle as the ſteel-yard; E g. Take two ſcales of unequal weights, in the proportion of 9 to 10, and hang them to each end of a balance, ſo that they may be in equilibrio; if then you take any weights, which are to one another as 9 to 10, and put the firſt in the firſt ſcale, and the ſecond in the other ſcale, they will equiponderate: but the cheat is immediately diſcovered by changing the weights and commodity to be weighed from one ſcale to the other: and the true weight of the commodity is always equal to a mean proportional between what it weighed in each ſcale. For let x and y be put for the reſpective lengths of the unequal brachia, F the matter to be weighed, a its weight when in one ſcale, and b, when in the other: then $Fx = ay$ and $Fy = bx$, by the nature of the balance, divide the former of theſe equations by the latter, we have $\frac{Fx}{bx} = \frac{ay}{Fy}$, whence $\frac{F}{b} = \frac{a}{F}$, conſequently $F^2 = ab$, and $F = \sqrt{a \times b}$.

Aſſay BALANCE, a very nice balance uſed in docimaſtical operations, to determine exactly the weight of minute bodies.

This balance ſhould be made of the beſt ſteel, and of the hardeſt kind; becauſe that metal is not ſo eaſily ſpoiled with ruſt, as iron; and it is more apt than any other to take a perfect poliſh, which at the ſame time prevents the ruſt.

The ſtructure of the aſſayer's ſcale is little different from that of common ſcales, otherwiſe than by its nicety and ſmallneſs. The longer the beam of it is, the more exact may the weight of a body be found; however, ten or twelve inches are a ſufficient length. Let the thickneſs of it be ſo little, that two drams may hardly be hung at either of its extremities, without its bending: for the largeſt weight put upon it ſeldom exceeds one dram. The whole ſurface of this beam muſt be altogether without ornaments, which only increaſe the weight, and gather duſt, &c. The beam is ſuſpended in a fork, the two legs of which are ſteel-ſprings joined at top, but kept together below with a braſs pliant claſp, parallel, and two lines and a half diſtant from each other. This claſp being taken off, and the legs of the fork being ſtretched out, the axis of the beam may be put into two holes made for that purpoſe at the ends of the legs, or be taken away from them. Let a very ſharp needle be fixed in the head of the fork, ſtanding perpendicularly downwards, if the fork is ſuſpended, and ſo long, as that it may almoſt touch the top of the tongue of the beam, put into the fork, when in equilibrio. This needle is the mark of the equilibrium; and, that the artiſts may be able to obſerve this, the legs of the fork muſt be broader in that place, and have an opening two or three lines wide; this fork may be adorned at pleaſure, provided the motion of the balance is not hindered by ſuch ornaments: then take two ſcales made of a thin plate of ſilver, one inch and a half in diameter, hanging on three ſmall ſilk ſtrings, almoſt as long as the beam, tied together at top, with a ſilver hook, in form of an S, and hang them to the extremities of the beam: a ſmaller ſilver diſh, or blued ſteel, ſomewhat leſs than one inch in diameter, belongs to each of theſe ſcales. You firſt put into theſe diſhes, with a pair of pincers, the bodies to be weighed, or with a ſpoon or a ſmall ſhovel, when they are pounded, and then you put them into the ſcales; therefore the ſmall diſhes muſt be perfectly equal in weight. We uſe them, that bodies may be more conveniently put into and taken out of the ſcales, and that theſe, which are vaſtly thin, may not be bent or ſoiled, and thence rendered falſe by wiping.

This balance is ſuſpended on a moveable braſs or copper-ſupport, which conſiſts of a pedeſtal, and of a column ſet upon it about twenty inches high, at the top of which comes out at right-angles an arm one inch long. At the extremity of this arm, put a ſmall pulley three lines in diameter: another at the top of the column, and a third near the bottom of it: all which pullies muſt turn very eaſily on their axes. At the diſtance of one inch and a half below the upper arm, let another arm, one inch and a half long come out of the column at right-angles, having a hole through it two lines long, a quarter of a line broad, and placed perpendicularly below the pulley of the upper arm, to receive a ſmall plate, one inch and a half long; and of ſuch breadth and thickneſs, as that it may freely move up and down, and yet not have too much play within the hole. This plate muſt alſo have a ſmall hook at each extremity.

And as ſuch a balance will hardly ſtand ſtill in the open air, and becomes falſe when ſpoiled with duſt; it muſt be put together with its ſupport into a ſmall caſe, as repreſented in plate XV. *fig.* 12, having glaſſes, *a*, *a*, *a*, at top and all round it, that you may ſee what is within.

Manner of uſing the Aſſay BALANCE.—Paſs a ſilk ſtring over the three pullies of the ſupport, and tie it at its upper extremity to the ſmall hook introduced into the hole of the inferior arm; then put the ſupport in the middle of the ſmall caſe, and paſs the other extremity of the ſilk ſtring below, through a hole bored in the middle of the lower part of the frame, containing the window in the fore part of the caſe, and faſten it to a ſmall weight of a cubic form. Suſpend the fork of the balance on the inferior hook of the plate. By this means, if you move backwards and forwards, the weight faſtened to the ſtring, placed upon the top of the drawer jutting out beyond the fore-part of the caſe, the balance within is either lifted up, or let down. But you muſt put the bodies to be weighed, and the weights themſelves, in the ſmall ſilver diſhes; and theſe, when loaded, into the ſcales, through the ſide windows, which muſt be opened for that purpoſe. When any thing is to be added to or taken out of them, you do it with the ſmall pincers, or, if it is powder, with the ſmall ſhovel or ſpoon: but you muſt let the balance down every time any thing is to be added or taken away, that the ſcales may reſt upon the bottom of the caſe; and ſhut the windows before the balance is lifted up again, eſpecially if the air is not perfectly calm.

Hydroſtatic BALANCE, an inſtrument contrived to determine accurately the ſpecific gravity of both ſolid and fluid bodies.

As the learned Mr. Graveſande has greatly improved the common hydroſtatic balance, and rendered it more accurate and expeditious, we ſhall give the reader a deſcription of it, according to the improvements of this ingenious author.

The figure of this machine (plate XV. *fig.* 10.) repreſents the balance in its hydroſtatic uſe. We ſhall firſt deſcribe the machine; then ſhew the new contrived artifice for exactneſs; and, laſtly, give an inſtance of its univerſal uſe. V C G is the ſtand or pillar fixed in the table. From the top at A hangs, by two ſilken ſtrings, the horizontal piece or bar B B; from which is ſuſpended, by a ring at *i*, the fine beam of a balance *l*, which is kept from deſcending too low on either ſide, by the gentle ſpringing piece *zxyx* fixed on the ſupporter M. The harneſs is annulated at *o*, to ſhew diſtinctly the perpendicular poſition of the examen, by the ſmall pointed index fixed above it. The ſtrings by which the balance is ſuſpended paſſing over two pullies, one on each ſide the piece at A, go down to the bottom on the other ſide, and are hung over the hook, by means of a ſcrew P, which is moveable about $\frac{1}{4}$th of an inch backwards and forwards; and therefore the balance may be raiſed or depreſſed as much: but if a greater elevation or depreſſion be required, the ſliding-piece S, which carries the ſcrew P, is readily moved to any part of the ſquare braſs rod V K, and fixed by means of a ſcrew.

The motion of the balance being thus provided for, the reſt of the apparatus is as follows: H H is a ſmall table fixed upon a piece D, under the ſcales *d* and *e*, and is moveable up and down in a long ſlit in the pillar above C, and faſtened at any part with a ſcrew behind. At the point at the middle of the bottom of each ſcale, is hung by a fine hook, a braſs wire *ad*, *ac*. Theſe paſs through two holes *m*, *m*, in the table; and to the wire *ad* is ſuſpended a curious cylindric wire *rs*, perforated at each end for that purpoſe. This wire *rs* is covered with paper graduated by equal diviſions, and is about five inches long. In the corner of the table at E, is fixed a braſs tube, in which a round wire *bl* is ſo adapted as to move neither too hard nor too freely by its flat head I: upon the lower part of this moves another tube Q, which has friction enough to cauſe it to remain in any poſition required; to this is fixed an index T, moving horizontally when the wire *bl* is turned about, and therefore may be eaſily ſet to the graduated wire *rs*.

To the lower end of the wire *rs* hangs a weight L, and to that a wire *pr* with a ſmall braſs ball *g* about $\frac{1}{4}$th of an inch in diameter. On the other ſide, to the wire *ac*, hangs a large glaſs bubble R to a horſe-hair. Let us, at preſent, ſuppoſe the weight L taken away, and the wire *pn* ſuſpended from S; and, on the other ſide, let the bubble R be taken away, and the weight F ſuſpended in its room at *c*. This weight F, we ſuppoſe to be ſuch as will keep in equilibrio with the ſeveral parts appended to the other ſcale, at the ſame time that the middle point of the wire *pn* is in the ſurface of the water in the veſſel N.

The wire *pn* is to be of ſuch a ſize, that the length of one inch ſhall weigh four grains. Hence it is evident, ſince braſs is eight times heavier than water, that for every inch the wire ſinks in the water, it will become half a grain lighter; and half a grain heavier for every inch it riſes out of the water: conſequently, by ſinking two inches below the middle point, or riſing two inches above it, the wire will become one grain lighter, or heavier.

And therefore, when the middle point is at the ſurface of the water in equilibrio, the index T be ſet to the middle point *a* of the graduated wire *rs*, and the diſtance on each ſide *ar* and *as* contain 100 equal parts; then, when in weighing bodies the weight is deſired to the hundredth part of a grain, it may eaſily be had by proceeding in the following manner.

Let the body to be weighed be placed in the ſcale *d*, and put the weights in the ſcale; and let theſe be ſo determined, that one grain more ſhall be too much, and one grain leſs too little. Then the balance being gently moved up or down by the ſcrew P, till the equilibrium be nicely ſhewn at *o*; and then, if the index T be at the middle point *a* of the wire *rs*, it ſhews the weights put into the ſcale *e* are juſt equal to the weight of the body.

But if the index T ſtand at any part between *a* and *r*, it ſhews the number of grains of the ſcale *e* were more than equal to the weight of the body in the ſcale *d*; becauſe the wire *pn* is now made lighter by ſinking below the middle point. Thus, ſuppoſe the weights put into the ſcale *e* were 1095 grains, and the index T cuts the 36 diviſion above *a*, it ſhews that 36 hundredth parts of a grain are to be added, or that the weight of the body is 1095,36 grains.

On the other hand, had the index ſtood at 36, the diviſion below *a*, it would have ſhewn the weights in the ſcale *e* were more than equal to the weight of the body by 36 hundredths of a grain, and that then the weight of the body was 1094,64 grains. By this method we find the abſolute weight of the body; the relative weight is found by weighing it hydroſtatically in water, as follows: Inſtead of putting the body in the ſcale *d*, as before, let it be appended with the weight F at the hook *e*, by a horſe-hair as at R, ſuppoſing the veſſel of water O were taken away; then the equilibrium being made, the index T ſtanding between *a* and *r*, at the 36th diviſion ſhews the weight of the body 1095,36 grains. As it thus hangs, let it be immerſed in the water of the veſſel O, and it will become lighter by much; the ſcale *e* will deſcend till the beam of the balance reſts on the ſupporter *z*. Then ſuppoſe 100 grains, put into the ſcale *d*, reſtored the equilibrium preciſely, ſo that the index T again pointed to the 36th diviſion above *a*; it is plain the weight of an equal bulk of water would, in this caſe, be exactly 100 grains. But if 100 grains in the ſcale *d*, cauſe it to preponderate a little, then by turning the ſcrew P, the balance may be raiſed, till the wire *pn* becoming heavier, reſtores the equilibrio. Let now the index T cut the 6th diviſion above *a*, then $36-6=30$, which ſhews that the wire *pn* is now $\frac{3}{10}$ of a grain heavier than before; therefore the weight of the water is only 99,7 grains: whence its gravity to that of the body is as 99,7 to 1095,36, as required.

After a like manner may this balance be applied to find the ſpecific gravities of fluids, which will not be difficult to thoſe who apprehend what has been already ſaid.

In practice, it will be neceſſary to uſe great precautions in every particular; the wire *p n* ſhould be oiled, and then wiped as clean as poſſible; enough will remain to prevent the water adhering thereto: alſo the balance ought to be raiſed very gently, and when come to an equilibrium, ſhould be gently agitated, to ſee if it will come ſo again.

BALANCING, among ſeamen, a ſingular method of contracting or reducing a ſail in a tempeſt, in contradiſtinction to reefing, which is common to all the principal ſails; whereas none are balanced but the mizen and main-ſails ſet on booms. Balancing the mizen is performed by rolling up a ſmall ſpace of it at the peek or upper-corner, and faſtening it to the mizen-yard. A boom-mainſail is balanced by tying a like portion of the outmoſt lower corner to the boom in the ſame manner, having firſt wrapped a piece of canvas round it to prevent its being cut or fretted by the line which faſtens it.

BALANI MARINI, certain multivalve ſhells, uſually growing in cluſters on the ſhells of the larger ſort of the ſea ſhell-fiſh: ſometimes they are found large, looſe, and petrified, at a great diſtance from the ſea; in which ſtate they are diſtinguiſhed by the name of balanitæ.

The balanus is a ſea ſhell-fiſh, of an oblong figure, approaching to that of an acorn, open at the mouth or top, and compoſed of ſeveral portions, or valves, from ſix to twelve in number, not moveable or looſe, as in the other bivalve or multivalve ſhells, but fixed in one another by an intermediate ſubſtance: the animal inhabiting this ſhell is called a triton. See TRITON.

BALASS, or BALLAS, the name of a kind of ruby. See the article RUBY.

BALAUSTINE, large roſe-like flowers, of a deep red colour, ſet in long bell-ſhaped tough cups. They are the produce of the wild or double-flowered pomegranate-tree, a low prickly tree or ſhrub, with long narrow leaves, bearing a browniſh acerb fruit, about the ſize of an orange; a native of the ſouthern parts of Europe; and cultivated in ſome of our gardens on account of the beauty and continuance of its flowers. The ſhops are uſually ſupplied with the dried flowers from abroad, tho' thoſe of our own growth do not appear to be any wiſe inferior to the foreign.

Balauſtine flowers are mildly aſtringent and corroborant; of a moderately rough and ſomewhat bitteriſh taſte, and of little or no ſmell or particular flavour. They give out their aſtringent matter, together with a pale red colour, both to water and rectified ſpirit: the extracts, obtained by inſpiſſating the tinctures, in which the active parts of the flower are concentrated, are pretty ſtrongly ſtyptic. The ſpirituous tincture is of a paler colour, and the extract in leſs quantity, and proportionably ſtronger in taſte, than the tincture and extract made with water. The ſpirituous extract, as well as the watery infuſion, ſtrikes an inky blackneſs with ſolution of chalybeate vitriol; a proof that the aſtringent matter of the balauſtine, after its ſeparation from the greateſt parts of the mucilaginous and other groſſer ſubſtances of the flower, is ſtill diſſoluble in water. *Lewis's Hiſtory of the Materia Medica.*

BALCONY, in architecture, a projecture in the front of a houſe, or other building, ſupported by pillars, or conſoles, and encompaſſed with a baluſtrade: or it is a kind of open gallery, for people to ſtand in, to behold any public ſhow, or for taking the air in. They are uſually level with the firſt floor, and are made of wood or iron.

BALDACHIN, or BALDAQUIN, in architecture, a building in form of a canopy, ſupported by pillars, and frequently uſed as a covering to inſulated altars. Some alſo uſe the term baldachin for the ſhell over a door.

BALE, in commerce, is ſaid of merchandizes packed up in cloth, and corded round very tight, in order to keep them from breaking, or preſerve them from the weather. Moſt of the merchandize capable of this kind of package, deſigned for fairs or exportation, ought to be in bales; and too much care cannot be taken in packing them, to prevent their being damaged. The bales are always to be marked and numbered, that the merchants to whom they belong may eaſily know them.

A bale of cotton yarn is from three to four hundred weight; of raw-ſilk, it is from one to four hundred; of lockram or dowlaſs, either three, three and a half, or four pieces.

BALE-GOODS, among the Engliſh merchants, are all ſuch as are imported or exported in bales; but the French give that name to certain hard-wares, and other ſort of merchandize, which come to Paris, and are commonly made by bad workmen, of indifferent materials.

BALISTA, a machine uſed by the ancients for ſhooting darts; it reſembled in ſome meaſure our croſs-bow.

The word is Latin, ſignifying a croſs-bow; and is derived from the Greek, βαλλω, to ſhoot, or throw.

Vegetius informs us, that the baliſta diſcharged darts with ſuch rapidity and violence, that nothing could reſiſt their force: and Athenæus adds that Agiſtratus made one of little more than two feet in length, which ſhot darts five hundred paces.

Plate XIII. *fig.* 2. repreſents the baliſta uſed in ſieges, according to the Chevalier Folard: 2, the baſe of the baliſta; 3, 4, upright beams; 5, 6, tranſverſe beams; 7, 7, the two capitals in the upper tranſverſe beam; the lower tranſverſe beam has alſo two ſimilar capitals, but cannot be ſeen in this figure; 9, 9, two poſts or ſupports for ſtrengthening the tranſverſe beams; 10, 10, two ſkains of cords faſtened to the capitals; 11, 11, two arms inſerted between the two ſtrands, or parts of the ſkains; 12, a cord faſtened to the two arms; 13, darts which are ſhot by the baliſta; 14, 14, curves in the upright beams, and in the concavity of which cuſhions are faſtened, in order to break the force of the arms which ſtrike againſt them with great force when the dart is diſcharged; 16, the arbor of the machine, in which a groove or canal, perfectly ſtraight, is formed, and in which the darts are placed in order to their being ſhot by the baliſta; 17, the nut of the trigger; 18 the roll or windlaſs, about which the cord is wound; 19, an iron hook, by which the cord is drawn towards the center, and the baliſta cocked; 20, a ſtage or table on which the arbor is in part ſuſtained.

BALIVO AMOVENDO, in law, was a writ for removing a bailiff from his office, for want of having ſufficient land in his bailiwick to anſwer the king and his people, according to the ſtatute of Weſtminſter, 2 reg. Orig. 78.

BALK, among builders, is ſometimes uſed for the ſummer-beam of a houſe; ſometimes for the poles and rafters, which ſupport the roofs of barns, &c. and ſometimes for the beams uſed in making ſea-holds.

BALL, a ſpherical and round body, either naturally ſo, or turned into that form. There are balls of common wood, of box, of iron, &c.

The word ball is alſo uſed to ſignify ſome tools and inſtruments of ſeveral arts and trades, becauſe they bear ſome reſemblance to balls. Thus,

A ball, or ſphere, is an inſtrument uſed by the optic-glaſs-makers: it is a piece of copper, iron, or ſome compound metal, cut into the form of an hemiſphere, or half ball, to which a handle is joined with maſtic; with this inſtrument, thoſe workmen make the concave-glaſſes which ſerve for teleſcopes, or ſpying glaſſes, microſcopes, and other inſtruments of that kind.

There are balls of ſpheres of ſeveral ſizes, according to the radius of the focus which the glaſſes require. They uſe thoſe balls for concave-glaſſes, by applying them hard, and turning them upon the plate of glaſs, which is laid flat upon the former; contrary to what is done with regard to convex glaſſes, which are worked in a kind of baſon. This difference excepted, the ſame methods are uſed in forming, ſmoothing, and poliſhing both ſorts. Balls are alſo ſet upon a lath or turning-wheel, as are likewiſe baſons for the ſame purpoſe. See the article TURNING.

BALL, in the military and pyrotechnical arts, is a compoſition of divers ingredients, generally of the combuſtible kinds, ſerving to burn, ſmoak, give light, &c.

Fire BALLS, *globi incendiarii*, are bags of canvas filled with gun-powder, ſulphur, ſalt-petre, pitch, &c. to be thrown by the ſoldiers, or out of mortars, in order to fire the houſes, incommoding trenches, advanced ports, or the like.

The preparations of fire balls, among the moderns, conſiſts of ſeveral operations, viz. making the bag, preparing the compoſition, tying, and, laſtly, dipping the ball.

The bags for this purpoſe are either oval or round.

The compoſition wherewith fire balls are filled, is various: To ten pounds of meal-gunpowder add two of ſalt-petre, one of ſulphur, and one of colophony; or, to ſix pounds of gunpowder, add four of ſalt-petre, four of ſulphur, one of powdered-glaſs, half a pound of antimony, as much camphor, an ounce of ſal-ammoniac, and four of common ſalt, all pulverized. Sometimes they even fill fire balls with hand granadoes.

For tying the fire balls, they prepare two iron rings, one fitted round the aperture, where the ball is to be lighted, the other near its baſe. A cord is tied to theſe rings in ſuch a manner, as that the ſeveral turns repreſent ſemi-circles of the ſphere cutting the globle thro' the poles: over the cords, extended according to the length of the ball, others are tied, cutting the former at right angles, and parallel to each other, making a knot at each interſection: laſtly, after putting in a leaden bullet, the reſt of the ſpace is filled with tow or paper. Thus compleated, the fire ball remains to be dipped in a compoſition of melted pitch four pounds, colophony two, and linſeed oil, or oil of turpentine, two; after dipping, they cover it round with tow, and dip again, till it be brought to the juſt diameter required.

Light BALLS, *globi lucentes*, are ſuch as diffuſe an intenſe light around; or they are balls which, being caſt out of a mortar, or the hand, burn for ſome time, and illuminate the adjacent parts.

Luminous or light balls for the hand, are made of ground powder, ſalt-petre, brimſtone, camphor, and borax, all ſprinkled with oil, and mouldered into a maſs with ſuet, and this is wrapped up in tow, with a ſheet of ſtrong paper over it. To fire it, they make a hole into it with a bodkin, into which they put ſome priming that will burn ſlow. Its uſe is to be caſt into any works they would diſcover in the night-time.

For the larger light balls, or thoſe to be thrown to a greater diſtance, they melt equal quantities of ſulphur, turpentine, and pitch; and herein dip an earthen or ſtone ball, of a diameter much leſs than that of the mortar out of which the fire ball is to be caſt: then rolling it in gunpowder, and covering it round with gauze, they dip it again, and repeat the reſt till it come to fit the cavity of the mortar: laſtly, they ſprinkle it around with gunpowder. This, being once kindled, will ſtrongly illuminate all round the place where it is thrown, and give opportunity to examine the ſtate and condition thereof.

Smoak or Dark BALLS, thoſe which fill the air with ſmoak, and thus darken a place to prevent diſcoveries.— To prepare a darkening ball, make an oval or ſpherical bag, melt roſin over the coals, and add an equal part of ſalt-petre not purified, alſo of ſulphur, and a fifth part of charcoal. The whole being well incorporated, put in tow firſt ſhred, and fill the bags with this compoſition, and dip it after the ſame manner as a fire ball.

Stink BALLS, *globi fœtentes*, thoſe which yield a great ſtench where fired to annoy the enemy.

Their preparation is thus: Melt ten pounds of pitch, ſix of roſin, twenty of ſalt-petre, eight of gun-powder, and four of colophony; to theſe add two of charcoal, ſix of horſe-hoofs cut ſmall, three of aſa-fœtida, one of ſtinking ſaracen, and any other offenſive ingredients. The reſt as in the former.

Sky BALLS, *globi aerii*, thoſe caſt on high out of mortars, and which, when arrived at their height, burſting like rockets, afford a ſpectacle of decoration. Sky balls are made of a wooden ſhell, filled with various compoſitions, particularly that of the ſtars of rockets.

Theſe are ſometimes intermixed with crackers and other combuſtibles, making rains of fire, &c.

Water BALLS, *globi aquatici*, thoſe which ſwim and burn a conſiderable time in the water, and at length burſt therein.

Theſe are made in a wooden ſhell, the cavity of which is filled with refined ſalt-petre, ſulphur, ſaw-duſt boiled in water of ſalt-petre, and dried; to which ſometimes other ingredients are added, as iron filings, Greek pitch, amber duſt, glaſs powdered, and camphor. The ingredients are to be ground, mixed up, and moiſtened with linſeed oil, nut oil, olive oil, hempſeed oil, or petrol. At the bottom is placed an iron coffin, filled with whole gunpowder, that the ball may at laſt burſt with a greater noiſe: and, laſtly, the ball is, by the addition of lead, or otherwiſe, made of the ſame ſpecific gravity with water.

BALL *of a Pendulum*, the weight at the bottom. In ſhorter pendulums, this is called the bob. See BOB.

BALL, among the Corniſh miners, ſignifies a tin-mine.

BALL, among printers, a kind of wooden tunnel ſtuffed with wool, contained in a leather cover, which is nailed to the wood, with which the ink is applied on the forms to be wrought off.

The preſs-man, holding one of theſe balls with either hand, firſt daubs them on the ink-block, and afterwards on the forms, which retain the ink neceſſary to make an impreſſion.

Horſe BALLS, among farriers, a kind of cordial medicine, adminiſtered in the form of balls, ſuppoſed of great virtue for feeding and ſtrengthening ſound, as well as healing and raiſing unſound horſes.

Markham's horſe balls are preparation of aniſeeds, carthamums, elicampane, and other ingredients wrought into a ſtiff paſte, and thence formed into balls. They are cleanſing and emollient, efficacious in colds, ſurfeits, and hard labour, and eſpecially uſeful where any of the chief viſcera are decayed: nothing raiſes a lean horſe ſo ſoon, being partly food and partly phyſic. *Ruſt. Dict. Farr. Dict.*

Chewing BALLS are thoſe which the horſe keeps champing or maſticating in his mouth, a conſiderable time, without ſwallowing. Theſe are chiefly uſed for a loſt appetite, a thing very incidental to horſes.

They are uſually made of aſa-fœtida, liver of antimony, juniper, bay-wood, and pellitory of Spain, beaten and incorporated into a maſs with verjuice. The method of adminiſtration is to wrap one of the balls in a linen cloth, and having a ſtring faſtened to it, make the horſe chew it three or four hours at a time. *Ruſt. Dict.*

BALL *Vein*, in mineralogy, a name given by the miners of Suſſex to a ſort of iron ore, common there, and wrought to conſiderable advantage. It yields not any great quantity of metal, but what it has runs freely in the fire; it is uſually found in looſe maſſes, not in the form of a ſtrata, and is often covered with one or more cruſts. It generally contains ſome ſparkling particles, and is uſually of a circular form in the perfect maſſes, thickeſt in the middle, and gradually thinner as it approaches the ſides. The ores of Suſſex in general are poor, but they require very little trouble in the working; ſo that a conſiderable profit is made annually from them.

BALL and SOCKET is an inſtrument made of braſs, with a perpetual ſcrew, ſo as to move horizontally, vertically, and obliquely; and is generally uſed for the managing of ſurveying inſtruments, and aſtronomical inſtruments.

BALLAD, or BALLET, a ſpecies of ſong, adapted to the lower claſs of people.

BALLANCE, or BALANCE, in mechanics; ſee BALANCE.

BALLANCE *of Trade*. See TRADE.

BALLANCE *of a Clock or Watch*. See the articles CLOCK and WATCH.

BALLAST, any heavy matter, as ſtones, gravel, iron, &c. thrown into the hold of a ſhip, in order to make her ſink a proper depth in the water, that ſhe may be capable of carrying a ſufficient quantity of ſail without overſetting.

The word is formed from the Flemiſh word, *belaſt*, which ſignifies the ſame thing.

BALLASTAGE, or LASTAGE; ſee LASTAGE.

BALLIAGE, in commerce, a ſmall duty paid to the city of London by aliens, and even denizens, for certain commodities exported by them.

BALLISTA. See the article BALISTA.

BALLOON, or BALLON, in a general ſenſe, implies any hollow body of a ſpherical form, be its compoſition or uſes what they will.

BALLOON, in chemiſtry, is a large receiver of a round form, and very ſhort neck.

BALLOON, in architecture, ſignifies a round ball or globe, placed on the top of a pillar, &c. by way of crowning.

BALLOON, in pyrotechny, is a kind of bomb made of paſte-board, and played off in fire-works, either in the air or water, in imitation of a real bomb.

BALLOTADE, or BALOTADE, in the manege, the leap of a horſe between two pillars, or on a ſtraight line, made with juſtneſs of time, and with the aid of the hand and calves of the legs; and in ſuch a manner, that, when his fore-feet are in the air, he ſhews nothing but the ſhoes of his hinder feet, without yerking out.

BALLS, or BALLETS, in heraldry, make a frequent bearing in coats of arms, though they are never called by thoſe names, but acquire other denominations from their ſeveral colours. Thus, when the colour is or, they are termed *beſants*; when argent, *plates*; when azure, *hurts*; when gules, *torteaux*; when vert, *pomeis*; when ſable, *agreſſes*; when purple, *golpes*; when tanne, *orenges*; and when ſanguine, *guzes*.

BALLUSTER, in architecture, a kind of ſmall pillar uſed in balluſtrades.

BALLUSTRADE, a row or ſeries of balluſters joined by a rail, and fixed on a terras or the top of a building by way of ſecurity; as alſo to incloſe balconies, altars, fonts, ſtaircaſes, &c.

BALM, or BALSAM; ſee BALSAM.

BALM, or BAUM, in botany; ſee BAUM.

BALNEUM, a term much uſed by chemiſts to ſignify a veſſel filled with ſome matter, as ſand, water, or the like, in which others are placed for performing various operations that require leſs heat than a naked fire.

BALNEUM *Arenoſum*, or *Siccum*, a ſand, or dry heat; a veſſel filled with ſand, aſhes, or filings of ſteel.

BALNEUM *Mariæ*, or *Maris*, a water bath, or a veſſel filled with water, which is made to boil, and in which the veſſels containing the ingredients are placed.

BALNEUM *Vaporis*, a vapour bath, or when the veſſel containing the ingredients, on which the proceſs is to be performed, is heated by the vapour ariſing from boiling water.

BALSAM, *Balſamum*, an oily, reſinous, and odorous ſubſtance, flowing either ſpontaneouſly, or by inciſion, from certain plants, of great virtues in the cure of ſeveral diſorders.

BALSAM *of Gilead*, or *of Mecca*, *Opobalſamum*, the moſt precious of all balſams; and commonly called balm of Gilead.

It is the produce of certain trees, which grew formerly in the valley of Jericho; but after the conqueſt of the Holy Land by the Turks, were removed to Grand Cairo, and afterwards to Mecca, where the balſam plantation is ſaid to be now guarded by janiſſaries, and the reſinous juice collected for the ſultan only.

We are not to imagine, that what is ſold by the druggiſts under the name of this balſam, at no very great price, is the true ſort: it is either the native juice of another kind of tree, or what is more probable, a compoſition of balſam of copaiba with diſtilled oils, &c. Hence we meet with opobalſams very different from one another, or agreeing only in external appearance. There is, or at leaſt was lately, a ſpecimen of the genuine balſam in the royal apotheca at Dreſden, received by king Auguſtus, among other preſents, from the Grand Signior himſelf.

The true balſam is of a pale yellowiſh colour, clear and tranſparent, about the conſiſtence of Venice turpentine; of a ſtrong, penetrating, agreeable, aromatic ſmell, and a ſlightly bitteriſh pungent taſte: by age it becomes yellower, browner, and thicker, loſing by degrees, like eſſential oils, ſome of its finer and more ſubtile parts. To ſpread, when dropped into water, all over the ſurface, and to form a fine, thin, rainbow-coloured cuticle, ſo tenacious, that it may be taken up entire by the point of a needle, were formerly held infallible criteria of the genuine opobalſam. But it has been obſerved, that other balſams, when of a certain degree of conſiſtence, exhibit theſe phænomena equally with the genuine.

This balſam, according to Proſper Alpinus, is obtained from a ſmall ever-green tree or ſhrub, about the ſize of the privet or cytiſus, with flexible branches, and a few leaves, reſembling thoſe of rue, or rather of the lentiſk tree, ſet in pairs along a middle rib, with an odd one at the end. The branches are covered with two membraneous thin barks, the outermoſt of a reddiſh brown colour, the inner greeniſh; the woody part is white. The flowers are of a purpliſh white colour, in ſhape like thoſe of acacia: the fruit is a ſmall reddiſh-black berry, containing yellow ſeeds.

The wood is ſaid to be inodorous, the bark fragrant and aromatic, the flowers highly odoriferous; the berries to be odorous, acrid, and bitter, and to yield a yellow liquor of the appearance of honey. The branches and dry berries have been ſometimes brought into Europe, and kept in the ſhops for medicinal uſe, the former under the name of *xylobalſamum*, the latter of *carpobalſamum*. But whatever ſmell or taſte theſe ſubſtances may have, when freſh, they have little of either as they come to us.

The precious balſam exſudes in very ſmall quantity, from ſlight inciſions made in the bark: according to the author above-mentioned, it is at firſt white, of a very ſtrong penetrating ſmell, of the turpentine kind, but ſweeter and more fragrant, and of a bitter, acrid, aſtringent taſte. It looks in part turbid and thick, like the oil newly expreſſed from olives; afterwards it grows extremely thin, limpid, and light; its colour changes to a greeniſh, then to a gold yellow, and, by long keeping, to that of honey: it now grows thick like turpentine, and loſes much of its fragrance.

Inferior ſorts of balſam are ſaid to be obtained by boiling the branches in water. When the liquor begins to boil, a thin oil ariſes to the ſurface, and on continuing the coction a groſſer and thicker one.

Mr. Geoffrey obſerves, that a ſolution of balſam of Gilead, made in ſpirit of wine, turns milky on being poured into water, but does not depoſit any precipitate; and that this mixture is uſed in France as a coſmetic. He ſays an equal quantity of oil of almonds is previouſly mixed with the balſam; but this ingredient can be of no uſe, as it totally ſeparates and falls to the bottom, whilſt the balſam diſſolves in the ſpirit.

It is uſed in medicine to open obſtructions of the lungs, and to heal eroſions from acrimony, and the worſt kinds of ulcerations. It is alſo preſcribed in aſthmas, pleuriſies, and whenever expectoration is neceſſary, in internal bruiſes, and to cleanſe the urinary paſſages.

BALSAM *of Tolu* is commonly of a thicker conſiſtence than the foregoing, and more of a browniſh colour. When freſh, it has an exceeding pleaſant ſmell, ſomewhat reſembling that of citrons.

It is ſaid to be the produce of New Spain, and to exſude in very hot weather from inciſions made in the bark of a ſmall tree of the fir kind, called tolu.

We have no particular deſcription of the tree which produces this balſam. Linnæus has given its generical characters, under the name of *toluifera*; and in theſe it differs greatly from the firs and pines, to which it is commonly reſembled. The balſam is one of the moſt elegant and grateful of the ſubſtances of this claſs, and does not loſe much of its fragrance when by age it grows conſiſtent. It yields very little eſſential oil in diſtillation, but impregnates the diſtilled water ſtrongly with its flavour. By diſſolving in this water, in a gentle warmth, a proper quantity of fine ſugar, we obtain a balſamic ſyrup, greatly ſuperior to that made in the common manner with a decoction of the balſam.

Its virtues are the ſame with that of Gilead, and is given in convulſions, and other diſorders of the breaſt, ſometimes in the form of pills, and ſometimes in electuary; but the beſt form of giving it is in emulſion, diſſolved in the yolk of an egg, and then mixed with water.

BALSAM *of Copaiba*, *Cophahu*, *Copaiſ*, *Campaiſ*, *Copalyva*, or *Gamelo*, is obtained from a tree of the ſame name, growing in the Brazils, near Rio de Janeiro.

This balſam is of a pale yellowiſh colour, and thin conſiſtence. It is obſervable, that on mixing this juice with the watery ſpirit of ſal ammoniac, made by quicklime, a frothing, or efferveſcence, as it is called, enſues, ſtronger and of longer continuance than that produced by the ſame ſpirit with any other natural balſam: by this mark we may diſtinguiſh the genuine copaiba from the thin reſin of the turpentine or fir tree, which is frequently mixed with or vended for it. This balſam is at preſent of very common uſe as a medicine.

It is obſervable alſo of this balſam, that on being diſtilled in a retort, it gives over towards the end of the operation, an oil of a fine blue colour, preceded by a limpid, and a yellowiſh or browniſh one. Diſtilled with water, it yields a large quantity of a limpid eſſential oil: from ſixteen ounces I have gained eight.

The copaiba-tree is one of the large foreſt trees of Brazil and ſome other parts of America. Mr. Ray calls it *Arbor balſamifera Brazilienſis fructu monos permo.* The leaves are roundiſh and oval, the flowers pentapetalous, the fruit a pod, containing a kernel like a filberd. The wood is of a deep red colour, and great hardneſs; and hence is employed in ornamental mechanic works, and is ſaid to be uſed alſo in dying. The balſam is extracted by making deep inciſions in the trunk of the tree, in the middle of the ſummer heats; if this operation is performed too early, no juice exſudes, in which caſe the wounds are for a time cloſed up. It is ſaid that twelve pounds of balſam iſſue from one tree in a few hours; but that after once bleeding, it never affords any more.

It is more deterſive and more fragrant than common turpentine; paſſes very quickly by urine, and greatly aſſiſts in cleanſing thoſe paſſages; for which reaſon it is frequently given in gonorrhæas, and all obſtructions and ulcerations of thoſe parts.

BALSAM *of Peru* is obtained from certain trees of Peru and Mexico, differing ſomewhat from one another in appearance, aud ſomewhat alſo in the quality of their juices.

The balſam tree deſcribed, by Piſo, under the name of *cabureiba*, has ſmall leaves like thoſe of the myrtle, and a thick aſh-coloured bark, covered with a very thin red one; under this is lodged a yellowiſh balſam, that impregnates the whole ſubſtance of the bark, which by age becomes more and more fragrant. Hernandez deſcribes this balſam-tree, as having leaves like thoſe of the almond, and a thick bark like cork, from which the balſam flows upon wounding the outer thin rind. Plunkenet mentions a tree of the ſame kind in Virginia, by the name of *Arbor Virginiana, Piſaminis folio, Baccata Benzoinum redolens.*

There are three ſorts of balſam of Peru: 1. A colourleſs or pale yellowiſh, called white, in appearance ſomewhat reſembling the opobalſam, and like it of a ſtrong ſmell: this is the native juice, collected and preſerved in the ſame ſtate wherein it iſſues from the tree. Among us, it is rarely or never met with. 2. A dry balſam, or the foregoing inſpiſſated by the ſun's heat, in calabaſhes, or gourd-ſhells, in which it is ſometimes brought into Europe: this has ſomewhat of a reddiſh colour, and ſtill ſmells very agreeably. 3. The common or black Peruvian balſam of the ſhops. This ſort is artificially extracted from the bark, branches, and leaves of the tree, by cutting them in pieces, and boiling them in water. The balſam is ſaid to ſeparate, and ariſe to the ſurface, from whence it is taken off. A portion of the gummy or other matter of the plant which the water extracts, is retained by the balſam, and falls to the bottom upon diſſolving it in ſpirit of wine. Pomet and others report, that this balſam is counterfeited or ſophiſticated with mixtures of expreſſed oils and other ſubſtances: but happily the balſam of Peru will not in any degree mingle with thoſe oils; in which reſpect it differs from almoſt all the other reſinous bodies.

This balſam is of a thick conſiſtence, like honey; of a dark black colour in the maſs, but when ſpread thin of a clear reddiſh or yellowiſh brown, of an agreeable ſtrong ſmell, ſomewhat approaching to that of a mixture of benzoine and ſtorax, and of a bitteriſh pungent taſte, eaſily inflammable, not in the leaſt miſcible with water, nor rendered turbid or white on being agitated with that fluid. It becomes ſoluble in water, like the other balſams, by the mediation of yolk of eggs, or of ſugar; when diſſolved by the latter, it ſoon ſeparates from the water, whilſt the former keeps it much longer ſuſpended.

In diſtillation with water, it yields a ſmall quantity of a fragrant eſſential oil. Hoffman prepares alſo a grateful ſpirit, by drawing over ſpirit of roſes from a mixture of the balſam with half its weight of ſalt of tartar, divided by moiſt ſand. Diſtilled in a retort with an open fire, it affords a butter like that of benzoine, and oftentimes a conſiderable quantity even of concrete ſaline flowers, ſimilar to thoſe procured from that reſin.

It is of a heating and drying quality, and is frequently uſed externally in the cure of wounds. The perfumers alſo uſe it on account of its agreeable ſmell.

Odoriferous BALSAMS are a fragrant kind of unguents, generally of a thick conſiſtence, compoſed of ſome fatty, denſe juice, joined with ſome diſtilled oils of various kinds.

Boerhaave's method of preparing theſe balſams, is this: Melt an ounce of fine pomatum, in a China veſſel, over a ſmall and perfectly clear fire; then gradually add a dram of white wax, ſhaved into thin pieces: after theſe are perfectly blended together, remove the veſſel from the fire; and when the matter begins to thicken in cooling, drop in, by ſlow degrees, a dram of any of the fragrant eſſential oils; keep the whole continually ſtirring, all the time the oil is dropping in, that it may perfectly mix: after which, ſet the veſſel in cold water, that the whole matter, immediately condenſing by the cold, may keep in the oil and ſpirit. When the balſam is thoroughly cold, put it immediately up in veſſels of lead or pewter; and, if theſe are cloſe covered, it will keep perfect a great many years.

Inſtead of pomatum and wax, the expreſſed oil of nutmeg may be uſed in this proceſs, after it has been waſhed in water, till perfectly inſipid, white, and inodorous.

If theſe balſams are required to be of any colour, it may be eaſily given at pleaſure. A ſcruple of fine cochineal, in fine powder, will tinge the balſam of a fine purple; or the ſame quantity of the inſpiſſated juice of buckthorn berries, to a fine green, a little native cinnabar, will turn it ſcarlet: turmeric, yellow; and ſmalt, to a beautiful blue. Any of theſe may be uſed at pleaſure, provided that they have no ill ſmell, or hurtful properties.

Theſe balſams are prepared as rich perfumes, to raiſe the languid ſpirit; and the nobleſt and richeſt of the eſſential oils ſhould therefore be uſed in them. The oils, principally directed by Boerhaave to this purpoſe, are thoſe of balm, calamus aromaticus, cinnamon, cedar, citron, cloves, jaſmin, lavender, white lillies, marjoram, mace, nutmegs, origanum, oranges, both thoſe of China and Seville; roſes, rhodium, and yellow ſaunders; to which may be added, the natural balſams of Peru and Gilead; theſe two being ſpontaneouſly fragrant without diſtillation. *Boerhaave's Chemiſtry.*

BALSAMICS, in pharmacy, ſoftening, reſtoring, healing, and cleanſing medicines, of gentle attenuating principles, very friendly to nature.

Theſe medicines, on account of their fine, ſubtile, and volatile oil, are not only grateful and agreeable to the conſtitution, but act upon the fluids, as well as the ſolids, of human bodies; diffuſing their virtues through every part, and ſupplying the blood and humours with a ſeaſonable reinforcement of ſulphureous, warm, and ethereal parts, increaſing their inteſtine motions, and conveying vigour to the vital juices.

Theſe medicines may be uſed with great ſucceſs, both internally and externally, in all diſeaſes of the head, nerves, ſpinal marrow, ſtomach and heart; ſuch as palſies, apoplexies, numbneſs and torpor of the ſenſes, weakneſs of the memory, difficulty of hearing, exceſſive weakneſs and faintings; they are alſo of ſingular ſervice in moſt diſorders of the ſtomach and inteſtines, and are exquiſitely adapted to the old and infirm.

BALSAMINA, *Balſamine*, in botany, the name of a genus of plants, whoſe flower is of the polypetalous anomalous kind; and is in ſome ſpecies, four-leaved, and, in others, ſix-leaved. In the four-leaved flowers, the upper leaf is arched, and the lower hollowed, and terminated by a tail, and the two ſide leaves are large. In the ſix-leaved flowers of this genus, the flower leaf has no tail.

In both the piſtil, which is furniſhed with two leaves, occupies the middle part of the flowers, and at laſt becomes a fruit; ſometimes turbinated at one end, or both, and ſometimes emulating the ſhape of a pod, conſiſting of ſeveral muſcles, as it were, and endued with an elaſtic force, and flying open with great violence. The ſeeds it contains are fixed to the axis or placenta.

Mr. Miller has enumerated nine, and M. Tournefort nineteen ſpecies of balſamina.

The common white, red, and purple kinds of this plant will come up in common ground, without any artificial heat; and even be the ſtronger, and flower better, than if raiſed on hot beds. All the other varieties are raiſed from ſeeds ſown on hot beds in the ſpring, and afterwards planted into pots and borders. But the fine double large kind, or immortal eagle-flower, as it is called, requires to be ſet on a freſh hot bed, after it has been raiſed on one, in order to bring it forward; otherwiſe it will not get into flower till late in the year, and will not ripen its ſeeds: there are two kinds of this beautiful ſpecies; one brought from the Weſt Indies, and called the cock's-ſpur, which produces large and ſtrong plants, but flowers very late; the other is from China, and called the immortal eagle-flower, and is one of the fineſt annual plants we have, producing large double flowers, and continuing a long time in flower, if ſheltered from violent winds and rain. This produces ſeeds very well with us; but, after a few years, they are apt to degenerate into ſingle flowers. When the young plants are raiſed in a hot bed, and are to be planted out into pots, ſuch are always to be preferred as have ſtalks finely ſpotted with red; for theſe always produce red and double flowers. *Miller's Dict.*

BAMBOE, or Bambow, as they ſpell that word in the Indies, in botany, the name of a plant that multiplies very much by its root, from which ſprings a ramous or branchy tuft, after the manner of the European reeds; of which, as well as the ſugar-cane, it is a ſpecies. The Indian bamboe is the largeſt kind of cane hitherto known. It is of an extraordinary height and bigneſs when it bears its bloſſom; each ſhoot or cane is often, at the bottom, as large as a man's thigh, and decreaſes gradually to the top, where it bears a bloſſom or flower like our reeds, in their proper ſeaſon.

The bamboe grows in all the maritime countries of the Eaſt Indies. Its leaves are like thoſe of the other canes or reeds, but neither ſo long nor ſo broad at their baſe. With theſe bamboes the Indians build their houſes, and make all ſorts of furniture, in a very ingenious manner. The wood is ſo hard and ſtrong, that they ſerve very well to make piles for ſupporting their little houſes, built over rivers, or in plains overflowed at ſome ſeaſons of the year with water. They alſo make, with this wood, all ſorts of utenſils for their kitchens and tables. The thickeſt bamboes ſerve to make the ſticks or poles, with which the ſlaves or other perſons carry thoſe ſorts of litters, which are called palanquins, ſo generally uſed in all the Eaſt. They alſo make of that wood a kind of pails, in which the water keeps extremely cool.

Don Ulloa, in his voyage to South America, has given us the following deſcription of the bamboe, great numbers of which grow near the river Guaiaquil. The bamboes, ſays he, are remarkable for their length and thickneſs, and the water contained in their tubes. Their uſual length is between ſix and eight fathoms; and though there is a difference in their ſize, the largeſt do not exceed ſix inches in diameter. The wood or ſide of the tube, is about ſix lines in thickneſs; ſo that when the bamboe is opened, it forms a board near a foot and an half in breadth: and hence it will not appear ſtrange that houſes ſhould be built of ſuch materials. From the time of their firſt appearance, till they attain their full perfection, when they are either cut down, or of themſelves begin to dry, moſt of their tubes contain a quantity of water; but with this remarkable difference, that at full moon they are entirely or very nearly full; and with the decreaſe of the moon, the water ebbs till at the conjunction little or none is to be found. This ingenious writer adds, that he has himſelf cut them at all ſeaſons; ſo that he advances nothing but what he knows to be true from frequent experience. He alſo obſerved, that the water during its decreaſe appeared turbid; but about the time of the full moon as clear as cryſtal. The Indians add another particular, that the water is not found in all the joints, one having water, and another not, alternately. This water is ſaid to be an excellent preſervative againſt the ill conſequence of any bruiſes; at leaſt it is drank as ſuch by all who come from the mountains, where ſuch accidents are unavoidable.

The bamboes being cut, they are left to dry; whence they acquire ſuch a degree of ſtrength, that they ſerve either for rafters, beams, flooring, or even maſts for balzas. Ships which load with cacao are alſo cieled with them, to preſerve the timbers from the great heat of that fruit. They are alſo uſed as poles for litters, and in an infinite number of other particulars.

BANANA-TREE, a ſpecies of the muſa or plantain, growing plentifully in both the Eaſt and Weſt Indies. Its leaves are near two yards long, and twelve inches wide. The fruit is ſix or ſeven inches long, and covered, when ripe, with a yellow and tender ſkin. It grows upon a ſtalk, bearing only one ſingle cluſter or bunch, which perhaps conſiſts of forty or fifty bananas. When the bunch is gathered, they cut off the ſtalk, otherwiſe it would bear no more fruit. The pulp of the fruit is as ſoft as marmalade, and of a very pleaſant taſte; and it is ſaid to be very nouriſhing, to excite urine, and provoke to venery.

BAND, in a general ſenſe, ſome ſmall, narrow ligament, wherewith any thing is bound, tied, or faſtened.

Band, in architecture, a general name for any flat, low member, or moulding, that is broad, but not very deep.

Band *of Soldiers*, in military affairs, thoſe who fight under the ſame flag or enſign.

Band *of Penſioners* are a company of one hundred and twenty gentlemen, who receive a yearly allowance of one hundred pounds for attending on his majeſty on ſolemn occaſions.

Band is alſo the denomination of a military order in Spain, inſtituted by Alphonſus XI. king of Caſtile, for the younger ſons of the nobility, who, before their admiſſion, muſt ſerve ten years, at leaſt, either in the army, or at court; and are bound to take up arms for the catholic faith againſt the infidels.

Band, in ſurgery; ſee Bandage.

BANDAGE, in ſurgery, a fillet, roller, ſwathe, &c. applied to any part of the body.

That bandages are very uſeful, and even neceſſary, for curing the diſorders of the human body, is evident, not only from the teſtimonies of Hippocrates, Galen, and other eminent phyſicians, but alſo from this, that there can ſcarcely be any operation, in ſurgery, performed ſucceſsfully without their aſſiſtance: for ſhould a ſurgeon perform an operation with the greateſt care, but miſcarry in the application of the bandage, all his endeavours would be to no purpoſe; and more eſpecially in the treatment of wounds, fractures, luxations, and amputations: and we often find, that, in fractures and luxations, after a proper reduction of the parts, the cure depends more on a ſkilful application of the bandage to the part affected, than on the medicines: and in the caſe of violent hæmorrhages, a proper application of the bandage and compreſſes proves the moſt effectual and ſpeedy remedy, as muſt be acknowledged by every one who has any ſkill in ſurgery; not to mention that the applying and making a bandage, after a genteel and ready manner, is juſtly reckoned among the good qualifications of a ſurgeon, as it gains him the eſteem of the ſpectators, and the confidence of his patient, which is of great influence in forwarding the cure; for both the one and the other judge of a ſurgeon's other abilities by his performance on ſuch occaſions.

By a bandage we underſtand a piece of linen cloth, of a ſhape and ſize ſuitable to the part of the body it is to be applied to: they are ſometimes of a ſquare figure, not unlike a napkin; but generally they are long and narrow, when deſigned for fractures, luxations, and wounds; or for retaining compreſſes, plaiſters, lint, or the like. The French make a diſtinction betwixt a band and a bandage: by the firſt they underſtand the looſe cloth, before it be applied; and, by the other, the band, when applied to the body.

There are various kinds of bandages; ſome are peculiar to one, and others common to ſeveral parts of the body: ſome again are ſimple, and others compound. Thoſe are called ſimple which are made of one entire piece of linen, without any other pieces joined to them: with reſpect to theſe, we are to obſerve to make them of linen, cut according to the length of the whole piece, and commonly of three or four fingers in breadth, ſuitable to the part of the body they are applied to.

Theſe ſimple bandages may be rolled up at one or both ends, as the ſurgeon ſhall think more proper or neceſſary.

There are four different ways of applying the ſimple bandage, which are diſtinguiſhed by as many different names.

1. The circular or annular bandage is when the upper rounds come exactly over the undermoſt. 2. The obtuſe or aſcia, in French, *doloires*, when the rounds aſcend or deſcend from each other, in the form of a ſcrew.

3. The repent, in French, *rampant*, when the bandage is applied to the part affected in rounds ſeparate, and at a little diſtance from each other.

4. Reflex, called by the French, *renverſee*; when the bandage muſt be inverted, and turned back, as in thoſe applied to the legs, or other parts of the body, of different thickneſs.

The matter of which bandages are generally compoſed, is linen cloth; the neceſſary conditions of which are, firſt, that it be clean, partly for decency, and partly that it may not be offenſive to the wound: for, as Galen obſerves, a ſurgeon ought to ſtudy cleanlineſs and neatneſs, as well as uſefulneſs, in his dreſſings. Secondly, that it be not quite new, but wore for ſome time, which will render it more ſoft and ſmooth; for new cloth, by its hardneſs and aſperity, would irritate, inflame, and make the parts itch; at the ſame time, it ought not to be wore thin, becauſe that would make the bandage too weak, and ſubject to break. Thirdly, it ſhould be ſtrong, conſiſting of threads neither very coarſe, nor very fine; ſince the firſt will make it uneaſy to the patient, and the other will render it liable to ſtretch. Fourthly, it ſhould have no looſe threads, knots, or hems, nor any ſeams that can be avoided; but if the length of the bandage ſhould make ſeams neceſſary, they ſhould be as even and as few as poſſible. Fifthly, and laſtly, as to length and breadth required in a bandage, that muſt be left to the diſcretion of the ſurgeon.

BANDALEER, or BANDELEER, in military affairs, a large leathern belt, thrown over the right ſhoulder, and hanging under the left-arm; worn by the ancient muſketeers, both for the ſuſtaining of their fire-arms, and for the carriage of their muſket charges, which being put up in little wooden caſes, coated with leather, were hung, to the number of twelve, to each bandaleer.

BANDELET, or BANDLET, in architecture, any little band, or flat moulding, as that which crowns the Doric architrave.

BANDEROLL, a little flag, in form of a guidon, extended more in length than breadth, uſed to be hung out on the maſts of veſſels, &c.

BANDITTI, a term peculiarly denoting companies of highwaymen, common in Italy and France; but ſometimes alſo uſed, in a more general ſenſe, for robbers, pirates, out-lawed perſons, ruffians, &c.

BANIANS, a religious ſect in the empire of the Mogul, who believe a metempſychoſis, and will therefore eat no living creature, nor even kill noxious animals; but endeavour to releaſe them when in the hands of others.

The Banians are ſaid to be ſo fearful of having communication with other nations, that they break their cups, if one of a different religion has drank out of them, or even touched them. It is ſaid, that if they happen to touch one another, they purify and waſh themſelves before they eat, or enter their own houſes. They carry, hanging to their necks, a ſtone, called tamberane, as big as an egg, and perforated in the middle, through which run three ſtrings: this ſtone, they ſay, repreſents their great god, and upon that account they have great reſpect ſhewn them by all the Indians.

BANISHMENT, a kind of puniſhment, whereby the guilty perſon is obliged to leave the realm.

There are two kinds of baniſhment; one voluntary, and upon oath; the other upon compulſion, for ſome crime or offence: the former, properly called abjuration, is now ceaſed; the latter is chiefly enjoined by judgment of parliament, or other courts of juſtice.

By Magna Charta, none ſhall be outlawed, or baniſhed his country, but by lawful judgment of his peers, according to the law of the land, 9 Hen. III. 29.

BANK, in commerce, a common repoſitory, where many perſons agree to keep their money, to be always ready at their call or direction: or certain ſocieties or communities, who take the charge of other people's money, either to improve it, or to keep it ſecure.

There are banks of various kinds, and different in the nature of their conſtitutions and eſtabliſhments; ſome are inſtituted wholly on the public account, and put under the direction of the magiſtrates, as the famous bank of Amſterdam, where the money depoſited therein ſhall be always kept for the uſe of the proprietors, and ſhall never be let out for profit or advantage.

Payments made by aſſignments upon this bank, are valued from 3 to 6 per cent. above the payment of the money in ſpecie, ariſing from an opinion that the proprietors entertain of the equity of its adminiſtration; for judging themſelves ſecure, that their money lies always ready at hand, they ſeldom draw out large ſums, but make their mutual payments by transferring the ſums from one man's account to another.

A ſecond ſort of bank is ſuch as conſiſts of a company of monied men, who being duly eſtabliſhed, and incorporated by the laws of their country, agree to depoſite a conſiderable fund, or joint ſtock, to be employed for the uſe of the ſociety; as lending money upon good ſecurity, buying and ſelling bullion, gold and ſilver, diſcounting bills of exchange, &c.

A third ſort is the banks of private men, or partnerſhips, who deal in the ſame way as the former, upon their own ſingle ſtock or credit; and ſuch are the Lombard-ſtreet, or other bankers, as they are called. There are public banks eſtabliſhed in moſt of the trading cities of Europe, as in Venice, London, Paris, Amſterdam, Hamburgh, &c. The bank of Venice is the moſt ancient. It is eſtabliſhed by a ſolemn edict of the commonwealth, which enacts, that all payments of wholeſale merchandize, and letters of exchange, ſhall be in bank notes; that all debtors ſhall be obliged to carry their money to the bank, and all creditors receive their money from the bank; ſo that payments are performed by a ſimple transfer, from the one perſon to the other. In matters of retail, effective payments are ſometimes made, which do not diminiſh, but rather augment the ſtock, by reaſon of the liberty of withdrawing their money at pleaſure.

BANK, in natural hiſtory, denotes an elevation of the ground, or bottom of the ſea, ſo as ſometimes to ſurmount the ſurface of the water, or at leaſt to leave the water ſo ſhallow, as uſually not to allow a veſſel to remain a float over it.

In this ſenſe, bank amounts to much the ſame as flat, ſhoal, &c. There are banks of ſand, and others of ſtone, called alſo ſhelves, or rocks. In the North-ſea they alſo ſpeak of banks of rice, which are large pieces of that matter floating. *Aubin. Dict. Marin.*

BANKS are uſually diſtinguiſhed by a buoy, poſt, or the like. On charts, ſand banks are uſually marked by little dots, and banks of ſtone, by croſſes. The colours of the buoys are alſo varied accordingly, ſand banks being denoted by light-coloured buoys, and rocks by black ones.

In large rivers, as the Elbe, &c. ſand banks, by high tides and inundations, are liable to change places; care is therefore taken to ſhift the buoys from time to time, to ſhew the true channel of the river.

An exact knowledge of the banks, their extent, and the depth of water on them, makes the moſt eſſential part of the ſcience of a pilot, and maſter of a ſhip; if the veſſel be large, and draw much water, great attention will be neceſſary to keep clear of the banks; on the contrary, if it be ſmall, the ſame banks afford a ſure aſylum, where it may brave the largeſt and ſtouteſt veſſels, which dare not follow it here. By means of this barrier, many ſmall craft have eſcaped its enemy.

BANKER, a perſon who traffics and negotiates in money; who receives and remits money from place to place by commiſſion from correſpondents, or by means of bills or letters of exchance.

In France, it is not requiſite that a man be a merchant, in order to carry on banking; for that trade is permitted to all ſorts of perſons, even to foreigners, ſo far as relates to foreign banking, or dealing by exchange.

In Italy, the trade of a banker does not derogate from nobility, which is the reaſon why moſt of the younger ſons of the quality apply themſelves to that employment, in order to ſupport their families. The monied gold-ſmiths, in the reign of king Charles the Second, firſt acquired this name. See BANK.

The Romans had two ſorts of bankers, whoſe office was much more extenſive than that of the bankers among us; theirs being that of public affairs, in whom were united the functions of a broker, agent, banker, and notory, managing the exchange, taking in money, aſſiſting in buying and ſelling, and drawing the writings neceſſary on all theſe occaſions.

BANKER, in bricklaying, a piece of timber whereon they cut the bricks.

The banker is ſix feet long, or more, according to the number of men to work at it, and nine or ten inches ſquare: it is to be laid on two piers of timber, three feet high from the floor they ſtand on.

BANKING, the making of banks to oppoſe the force of the ſea, rivers, or the like, and ſecure the land from being over-flowed thereby.

With reſpect to the water which is to be kept out, this is called banking; with reſpect to the land, which is thereby to be defended, imbanking.

BANKING, in a ſalt work, the raiſing a fence againſt the ſea, whereby its waters may be kept out, excepting ſo much as is neceſſary for the preparation of the ſalt.

BANKRUPT, any perſon, either man or woman, that by trading hath gotten other perſons goods into his or her hands, and concealeth himſelf from his creditors. It is not buying or ſelling of lands, but of perſonal things, that will make a perſon liable to be a bankrupt; nor is it buying only, but both. Every one that gets his livelihood by buying and ſelling in trade, may fall under a ſtate of bankruptcy upon his failing: but adventurers in the Eaſt India company, members of the bank of England, or of the South-Sea company, ſhall not be adjudged bankrupts, in reſpect of their ſtock: alſo no perſon concerned as receiver-general of the taxes, &c. ſhall be a bankrupt. If a merchant gives over trade, and ſome years after becomes not ſolvent for money owed while a merchant, he is a bankrupt; but if for new debts continued on new ſecurity, it is otherwiſe.

BANKRUPTCY, the failure, abſconding, and relinquiſhing of traffic in a merchant, a banker, or any other trader. See the article BANKRUPT.

The French make this difference between a bankruptcy and a failure, that the firſt is ſuppoſed voluntary and fraudulent, and the latter conſtrained and neceſſary, by means of accidents, &c. A failing, breaking, or ſtopping of payment, diminiſhes the merchant's credit; but does not note him with infamy, as bankruptcy does.

When a merchant fails to appear at the Exchange, without apparent reaſon, it is called a failing of preſence: the bankruptcy becomes open from the day he abſconds, or the ſeal is fixed to his effects.

BAN, or **BAN**, *Bannum*, or *Bannus*, in the feudal law, a ſolemn proclamation or publication of any thing. Hence the cuſtom of aſking, or bans, before marriage.

BANN, in military affairs, a proclamation made in the army by beat of drum, ſound of trumpet, &c. requiring the ſtrict obſervance of diſcipline, either for the declaring a new officer, or puniſhing an offender.

BANN *of the Empire*, an imperial proſcription, being a judicial puniſhment, wherewith ſuch as are neceſſary to diſturbing the public peace, are judged unworthy of the immunities and protection of the empire, and are outlawed or baniſhed, &c.

BANNER denotes either a ſquare flag, or the principal ſtandard belonging to a prince.

We find a multiplicity of opinions concerning the etymology of the word banner; ſome deriving it from the Latin *bandum*, a band or flag; others, again, from the German *ban*, a field or tenement, becauſe landed men alone were allowed a banner; and, finally, there are ſome who think it is a corruption of *panniere*, from *pannus*, cloth, becauſe banners were originally made of cloth.

BANNERET, an ancient order of knights, or feudal lords, who poſſeſſing ſeveral large fees, led their vaſſals to battle under their own flag, when ſummoned thereto by the king.

This order is certainly moſt honourable, as it never was conferred but upon ſome heroic action performed in the field. Anciently there being but two kinds of knights, great and little, the firſt were called bannerets, the ſecond batchelors; the firſt compoſed the upper, and the ſecond the middle nobility.

In France they are ſaid to tranſmit their degree to their poſterity: but in England it dies with them. We have had none of this order created in England, ſince the time of king Charles I. ſo that this order is now become extinct among us.

The form of the banneret's creation was this; on a day of battle, the candidate preſented his flag to the king, or general, who cutting off the train, or ſkirt thereof, and making it a ſquare, returned it again; the proper banner of bannerets, who, from hence, are ſometimes called knights of the ſquare flag.

BANQUET, in the manege, that ſmall part of the branch of a bridle that is under the eye, which being rounded like a ſmall rod, gathers and joins the extremities of the bitt to the branch, and that in ſuch a manner, that the banquet is not ſeen, but covered by the cope, or that part of the bitt that is next the branch.

BANQUET *Line*, an imaginary line drawn, in making a bitt along the banquet, and prolonged up or down to adjuſt the deſigned force or weakneſs of the branch, in order to make it ſtiff or eaſy.

BANQUET, or **BANQUETTE**, in fortification, a little foot bank, or elevation of earth, forming a path, which runs along the inſide of a parapet, upon which the muſketeers get up in order to diſcover the counterſcarp, or to fire on the enemy in the moat, or in the covert-way.

BANTAM-WORK, a kind of Indian painting, and carving on wood, reſembling Japan work, only more gay, and decorated with a great variety of gaudy colours.

Bantam work is of leſs value among the connoiſſeurs, though ſometimes preferred, by the unſkilful, to the true Japan work. Formerly it was in more uſe, and eſteem, than at preſent, and the imitation of it much practiſed by our japanners. There are two ſorts of Bantam, as well as of Japan work; as, in the latter, ſome are flat, lying even with the black, and others high and emboſſed: ſo, in Bantam-work, ſome are flat, and others in-cut, or carved into the wood, as we find in many large ſcreens; with this difference, that the Japan artiſts work chiefly in gold and other metals, and thoſe of Bantam generally in colours, with a ſmall ſprinkling of gold here and there: for the flat Bantam work is done in colours, mixed with gum water, proper for the thing deſigned to be imitated. For the carved, or in-cut kind, the method of performing it is thus deſcribed by an ingenious artiſt: 1. The wood is to be primed with whiting and ſize, ſo often, till the primer lie near a quarter of an inch thick; then it is to be water-plained, i. e. rubbed with a fine wet cloth, and, ſome time after, rubbed very ſmooth, the blacks laid on, varniſhed up with a good body, and poliſhed well, though with a gentle hand. This done, the deſign is to be traced out with vermillion and gum-water, exactly in the manner wherein it is intended to be cut; the figures, trees, buildings, &c. in their due proportion; then the graver is applied, with other tools of proper ſhapes, differing according to the workman's fancy: with theſe he cuts deep or ſhallow, as is found convenient, but never deeper than the whiting lies; the wood being never to feel the edge of the inſtrument. Lines, or parts of the black, are ſtill to be left for the draperies, and other out-lines, and for the diſtinction of one thing from another; the rule being to cut where the white is, and leave the black untouched. The carving being finiſhed, then take to the pencil, with which the colours are laid into the cut work: after this, the gold is to be laid in thoſe places which the deſign requires; for which purpoſe, a ſtrong thick gum-arabic water is taken, and laid with a pencil on the work; and, while this remains wet, leaf-gold is cut with a ſharp ſmooth edged knife, in little pieces, ſhaped to the bigneſs and figure of the places where they are to be laid. Theſe being taken up with a little cotton, they daub them with the ſame cloſe to the gum-water, which affords a rich luſtre. The work thus finiſhed, they clear up the black with oil, taking care not to touch the colours. The European workmen ordinarily uſe braſs duſt, which is leſs bright and beautiful. *Park. Treat. of Japan*, c. 13. p. 37, *& ſeq.*

BAPTISM, in theology, the ceremony of waſhing; or a ſacrament whereby a perſon is admitted into the Chriſtian church.

The word is formed from the Greek, *βαπτιζω*, of *βαπτω*, to dip or waſh.

Grotius is of opinion, that the rite of baptiſm had its original from the time of the deluge; immediately after which he thinks it was inſtituted in memory of the world having been purged by water. Some learned men think it was added to circumciſion, ſoon after the Samaritan ſchiſm, as a mark of diſtinction to the orthodox Jews. Spencer, who is fond of deriving the rites of the Jewiſh religion from the ceremonies of the Pagans, lays it down as a probable ſuppoſition, that the Jews received the baptiſm of proſelytes from the neighbouring nations, who were wont to prepare candidates for the more ſacred functions of their religion by a ſolemn ablution; that, by this affinity of ſacred rites, they might draw the Gentiles to embrace their religion, and the proſelytes (in gaining of whom they were extremely diligent) might the more eaſily comply with the tranſition from Gentiliſm to Judaiſm. In confirmation of this opinion, he obſerves; firſt, that there is no divine precept for the baptiſm of proſelytes, God having enjoined only the rite of circumciſion, for the admiſſion of ſtrangers into the Jewiſh religion. Secondly, that, among foreign nations, the Egyptians, Perſians, Greeks, Romans, and others, it was cuſtomary that thoſe who were to be initiated into their myſteries, or ſacred rites, ſhould be firſt purified by dipping their whole body in water. That learned writer adds, as a farther confirmation of his opinion, that the cup of bleſſing likewiſe, added to the paſchal ſupper, ſeems plainly to have been derived from a pagan original: for the Greeks, at their feaſts, had one cup, called *ποτηριον αγαθȣ δαιμονος*, the cup of the good dæmon, or god, which they drank at the concluſion of their entertainment, when the table was removed. Since then a rite of Gentile original was added to one of the Jewiſh ſacraments, viz. the paſſover, there can be no abſurdity in ſuppoſing, that baptiſm, which was added to the other ſacrament, namely circumciſion, might be derived from the ſame ſource. In the laſt place, he obſerves, that Chriſt, in the inſtitution of his ſacraments, paid a peculiar regard to thoſe rites which were borrowed from the Gentiles: for, rejecting circumciſion and the paſchal ſupper, he adopted into his religion baptiſm and the ſacred cup: thus preparing the way for the converſion and reception of the Gentiles into his church.

It is to be obſerved, under this head of Jewiſh baptiſm, that the proſelyte was not to be baptiſed, till the wound of circumciſion was perfectly healed; that then the ceremony was performed by plunging him into ſome large, natural, receptacle of water; and that baptiſm was never after repeated in the ſame perſon, or in any of his poſterity, who derived their legal purity from the baptiſm of their anceſtor.

In the primitive Chriſtian church, the office of baptiſing was veſted principally in the biſhops, and prieſts, or paſtors of the reſpective pariſhes: but, with the conſent of the biſhop, it was allowed to the deacons, and, in caſes of neceſſity, even to laymen, to baptiſe; but never, under any neceſſity whatever, was it permitted to women to perform this office. Nor was it enough, that baptiſm was conferred by a perſon called to the miniſtry, unleſs he was alſo orthodox in the faith. This became matter of great buſtle in the church; and hence aroſe the famous controverſy between Cyprian, and Stephen biſhop of Rome, concerning the re-baptiſing thoſe who had been baptiſed by heretics, Cyprian aſſerting that they ought to be re-baptiſed, and Stephen maintaining the contrary opinion.

What opinion the church had of the validity of baptiſm, when performed even by perſons not veſted with a ſacred character, appears from the remarkable ſtory of Athanaſius, who, when a boy, and being at play with his companions, was choſen biſhop, and others, perſonating catechumens, were baptiſed by him with the uſual ceremonies; which baptiſm was adjudged to be valid by Alexander, the then biſhop of Alexandria.

The perſons baptiſed were either infants, or adults. To prove that infants were admitted to the ſacrament of baptiſm, we need only uſe this argument; none were admitted to the euchariſt till they had received baptiſm: but in the primitive church, children received the ſacrament of the Lord's-ſupper; as appears from what Cyprian relates concerning a ſucking child, who ſo violently refuſed to taſte the ſacramental wine, that the deacon was obliged forcibly to open her lips, and pour it down her throat. Origen writes, that children are baptiſed for the purging away of the natural filth and original impurity inherent in them. We might add the teſtimonies of Irenæus and Cyprian; but it will be ſufficient to mention the determination of an African ſynod, held A. D. 254, at which were preſent ſixty-ſix biſhops. The occaſion of it was this: A certain biſhop, called Fidus, had ſome ſcruples concerning the time of baptiſing infants, whether it ought to be done on the ſecond, or third day, after their birth, or not before the eighth day, as was obſerved with reſpect to circumciſion under the Jewiſh diſpenſation. His ſcruples were propoſed to this ſynod, who unanimouſly decreed, that the baptiſm of children was not to be deferred ſo long, but that the grace of God, or baptiſm, ſhould be given to all, and moſt eſpecially unto infants.

As for the time, or ſeaſon, at which baptiſm was uſually adminiſtered, we find it to have been reſtrained to the two ſolemn feſtivals of the year; Eaſter and Whitſuntide: at Eaſter, in memory of Chriſt's death and reſurrection, correſpondent to which are the two parts of the Chriſtian life, repreſented and ſhadowed out in baptiſm, dying unto ſin, and riſing again unto newneſs of life; and at Whitſuntide, in memory of the Holy Ghoſt's being ſhed upon the Apoſtles, the ſame, in ſome meaſure, being repreſented and conveyed in baptiſm. It is to be obſerved, that theſe ſtated returns of the time of baptiſm related only to perſons in health: in other caſes, ſuch as ſickneſs, or any preſſing neceſſity, the time of baptiſm was regulated by occaſion and opportunity.

The place of baptiſm was at firſt unlimited; being ſome pond or lake, ſome ſpring or river, but always as near as poſſible to the place of public worſhip. Afterwards they had their baptiſteries, or, as we call them, fonts, built at firſt near the church, then in the church-porch, and at laſt in the church itſelf. There were many in thoſe days who were deſirous to be baptiſed in the river Jordan, out of reverence to the place where our Saviour himſelf had been baptiſed.

The perſon to be baptiſed, if an adult, was firſt examined by the biſhop, or officiating prieſt, who put ſome queſtions to him; as firſt, whether he abjured the devil and all his works; ſecondly, whether he gave a firm aſſent to all the articles of the Chriſtian faith: to both which he anſwered in the affirmative. Concerning theſe baptiſmal queſtions, Dionyſius Alexandrinus, in his letter to Xiſtus, biſhop of Rome, ſpeaks of a certain ſcrupulous perſon in his church, who, being preſent at baptiſm, was exceedingly troubled when he heard the queſtions and anſwers of interrogatories were anſwered by his ſponſors, or godfathers. Whether the uſe of ſponſors was as old as the Apoſtles days, is uncertain: perhaps it was not, ſince Juſtin Martyr, ſpeaking of the method and form of baptiſm, ſays not a word of them.

BAPTISMAL, ſomething belonging to baptiſm; thus we ſay, baptiſmal vow, fonts, preſents, &c.

BAPTISTS, in church hiſtory, the name by which the anabaptiſts love to diſtinguiſh themſelves. See Anabaptists.

BAPTISTERY, the place in which the ceremony of baptiſm is performed. In the ancient Chriſtian church, it was one of the exedræ or buildings diſtinct from the church itſelf. So Paulinus, biſhop of Nola, ſpeaking of the magnificence of his friend Severus, ſays he built two churches and a baptiſtery between them both. It conſiſted of a προαυλιον οικον, a porch, or ante-room, where the perſons to be baptized made their confeſſion of faith, and an εσωτερον οικον, or inner-room, where the ceremony of baptiſm was performed. Thus it continued till the ſixth century, at which time the baptiſteries began to be taken into the church porch, and afterwards into the church itſelf.

The baptiſteries were very large and capacious, becauſe the ſtated times of baptiſm returning but ſeldom, there were uſually great multitudes to be baptized at the ſame time.

Some have confounded the baptiſtery, or place of baptiſm, with the font, in which the catechumen was plunged: but the baptiſtery was, properly ſpeaking, the whole houſe, or building, in which the font ſtood; which latter was only the fountain or pool of water in which the immerſion was performed.

Some learned men have obſerved, that anciently there was but one baptiſtery in a city, and that at the biſhop's church. Some remains of this ancient cuſtom are ſtill to be obſerved in ſeveral great cities of Italy: for Durantus informs us, that, at Piſa, Bononia, Orvieto, Parma, and even at Florence itſelf, they have but one baptiſtery and font for the whole city at this day. In length of time, baptiſteries were ſet up in country pariſhes, with the ſpecial allowance however of the biſhop.

BAR, in a general ſenſe, denotes a ſlender piece of wood or iron for keeping things cloſe together.

Bar, in courts of juſtice, an incloſure made with a ſtrong partition of timber, where the council are placed to plead cauſes. It is alſo applied to the benches where the lawyers or advocates are ſeated, becauſe anciently there was a bar to ſeparate the pleaders from the attorneys and others. Hence our lawyers, who are called to the bar, or licenſed to plead, are termed barriſters, an appellation equivalent to licentiate in other countries.

Bar, in law, a plea of a defendant which is ſaid to be ſufficient to deſtroy the plaintiff's action. It is divided into bar ſpecial, bar to common intendment, bar temporal, and bar perpetual. Bar ſpecial falls out upon ſome ſpecial circumſtances of the caſe in queſtion, as where an executor being ſued for his teſtator's debt, pleads that he had no goods in his hands at the day on which the writ was ſued out. Bar to common intendment is a general bar, which commonly diſables the plaintiff's declaration. Bar temporary is ſuch as is good for the preſent, but may afterwards fail; and bar perpetual is that which overthrows the plaintiff's action for ever. In perſonal actions, once barred, and ever ſo, is the general rule, but it is intended, where a bar is to the right of the cauſe, not where a wrong action is brought.

Bar, in heraldry, an ordinary reſembling the feſs, but much ſmaller.

It differs from the feſs only in its narrowneſs. The feſs is alſo confined to a ſingle place, whereas the bar may be placed in any part of the ſhield.

Bar, in horſemanſhip, implies the higheſt part of a horſe's mouth, between the grinders and tuſhes, that part only which lies under and at the ſide of the bars, retaining the name of gum.

Bar, in muſic, a ſtroke drawn perpendicularly acroſs the lines of a piece of muſic, including, between every two bars, a certain quantity, or meaſure of time, which is different, according as the muſic is either triple or common. In the former the meaſure of three crotchets is included, in the latter four. The principal uſe of bars is to regulate the beating of time.

Bar, in hydrography, implies a bank of ſand, gravel, &c. lying before the mouth of a river, harbour, &c. which always obſtructs the paſſage, and ſometimes totally prevents the navigation.

BAR-MASTER, among miners, the perſon who keeps the diſh, or gage, for meaſuring the ores.

Bar-Shot. See Shot.

BARACKS. See Barracks.

BARALIPTON, among logicians, the firſt indirect mode of the firſt figure of ſyllogiſm.

When the two firſt propoſitions are general, and the third particular, the middle term being the ſubject in the firſt propoſition, and the predicate in the ſecond, the ſyllogiſm is ſaid to be in baralipton. The following is of this kind:

Ba. Every evil ought to be feared;
ra. Every violent paſſion is an evil;
lip. Therefore ſomething that ought to be feared is a violent paſſion.

BARALOTTS, *Baralotti*, a ſect of heretics as Bologna in Italy, among whom all things, even their wives and children, were in common. They were alſo called *obedientes*, or compliers, becauſe they readily complied with every thing that tended to promote debauchery.

BARANGI, officers among the Greeks of the Lower Empire, who were intruſted with the keys of the city gates, where the emperor reſided. Codinus ſays, they were officers who kept guard at the door of the emperor's bed-chamber, or dining-room.

BARBACAN, or Barbican, properly ſignifies the outer wall, or exterior defence of a city or fortreſs.

Barbacan alſo implies a fort at the entrance of a bridge, or in the out-let of a city, having a double wall with towers.

It likewiſe denotes an aperture made in the walls of a fortreſs, to fire through upon the enemy.

Barbacan, in architecture, is a canal or opening left in the wall, in order to give room for the water to run in and out, when buildings are erected in places liable to be overflowed, &c.

BARBADOES-TAR, *Petroleum Barbadenſe*, in the materia medica, a fluid bitumen, or mineral oil, of a reddiſh colour, and thick conſiſtence, approaching to that of treacle, or common tar. It is found in ſeveral of our American dominions, eſpecially in the iſland from which it receives its name.

This bitumen is greatly eſteemed by the Americans as a ſudorific, and frequently given in diſorders of the breaſt. It is alſo uſed as an external diſcutient and antiparalytic.

BARBARA, in logic, is a name given by the ſchoolmen to the firſt mode of the firſt figure of ſyllogiſms.

A ſyllogiſm, in barbara, is that whoſe propoſitions are all univerſal and affirmative; the middle term being the ſubject of the firſt propoſition, and the attribute in the ſecond: as,

Bar. Every wicked man is miſerable;
ba. All tyrants are wicked men;
ra. Therefore all tyrants are miſerable.

BARBARISM, in grammar, an offence againſt the purity of ſtyle or language; or a hard and coarſe expreſſion, never uſed by polite authors.

BARBE, a name uſually given to a Barbary horſe, greatly eſteemed for its beauty and ſwifneſs.

Barbe, in the military art, is a term applied to the firing of cannon. Thus, to fire in battle, is to fire the cannon over the parapet, inſtead of firing through the embraſures. The parapet muſt not be above three feet and a half high, otherwiſe it will be impoſſible to fire in this matter.

Barbe, among our anceſtors, ſignified the armour of a knight's horſe.

BARBEL, *Barbus*, the name of a river fiſh, and ſo called from its having a barb or beard under its noſe.

BARBERY, in botany; ſee Berberis.

BARBLES, or Barbs, in farriery, are ſmall excreſſences under the tongue, and which may be diſcovered by drawing it aſide, and cured by cutting them cloſe off, and waſhing the part with brandy, or ſalt and water.

BARCALAO, a ſpecies of cod reſembling that of Newfoundland, caught in ſeveral parts of the South-ſea, particularly on the coaſt of the iſland of Juan Fernandes.

BARCA-LONGA, a ſmall coaſting veſſel in Spain, fitted with pole maſts, (i. e. ſingle maſts, without any top-maſt or upper-part) and high ſquare ſails, called lug-ſails.

BARD, a poet among the ancient Gauls and Britons, who ſung the praiſes of heroes, in order to recommend virtue, and compoſe the diſſenſions among mankind.

Some writers have confounded the bards with the druids; but this is a miſtake. They had their name from their office of chanting hymns, which were accompanied with muſical inſtruments, and conſidered as the dictates of their gods; ſo that it is no wonder they were held in the higheſt eſteem. It is even ſaid that they could at any time ſtop whole armies at the point of engaging by their interpoſition.

BARDANA *Major*, burdock or clotbur, in botany, a biennial plant, common by road ſides, ſufficiently known by its ſcaly heads or burs: the leaves are very large, ſhaped ſomewhat like a heart, of a deep green colour above, and whitiſh underneath; the ſeeds flatted, nearly oval, ſomewhat crooked, ſlightly ſtriated, of a dark brown or blackiſh colour: the root large, ſtraight, browniſh on the outſide and white within, compoſed of a thick cortical part, and a ſpongy medullary ſubſtance, with more or leſs of a woody ſeptum between them.

The roots of burdock have very little ſmell, and a weak taſte, chiefly ſweetiſh, mixed as it were with a ſlight bitteriſhneſs and roughneſs. Boiled in water, they impart a browniſh colour, and a ſoft vapid kind of taſte: extracts made from them, both by water and by rectified ſpirit, are weakly ſweetiſh, bitteriſh, ſubaſtringent, and ſubſaline. Theſe roots are recommended as mild diuretics, diaphoretics, and ſweeteners, in ſcorbutic, rheumatic, gouty, and venereal diſorders; and are ſuppoſed to be of ſimilar or ſuperior virtue to china-root and ſarſaparilla, to which, in their ſenſible qualities, they have a conſiderable reſemblance. They are uſed chiefly, and to the beſt advantage, in the form of a decoction: two ounces of the dried root are boiled in three pints of water, till one pint is waſted, and a pint or more of the ſtrained liquor taken warm every day.

The expreſſed juice of the leaves has been ſometimes given to the quantity of a quarter of a pint or more, in the ſame intentions. The leaves are bitterer and more ſaline than the roots, and have nothing of their ſweetiſhneſs: the juice, depurated, and inſpiſſated to the conſiſtence of an extract, diſcovers a moderately ſtrong, penetrating, ſaline bitterneſs.

Theſe ſeeds alſo are bitteriſh and ſlightly aromatic; and have been given, in doſes of a dram, as a diuretic, and as an aperient in diſorders of the breaſt. A good deal of care is requiſite, to clear them thoroughly from the prickly with which they are covered, and which, if ſwallowed, immediately diſcovers how much it offends the parts it paſſes through, by the uneaſy ſenſations it produces in the throat.

BARDESANITES, in eccleſiaſtical hiſtory, a ſect of heretics in the ſecond century, the followers of Bardeſanes, a native of Edeſſa, in Meſopotamia.

They held the devil to be a ſelf-exiſtent independant Being; and taught that Chriſt was not born of a woman, but brought his body with him from heaven; maintained that God himſelf was ſubject to fate; and that virtue and vice depended on the influence of the ſtars.

BARGAIN, in commerce, a contract or agreement in buying and ſelling.

BARGAIN *and Sale*, in law, is properly a contract made of manors, lands, and other things, transferring the property thereof from the bargainer to the bargainee, for a conſideration in money.

This method of conveying lands was created and eſtabliſhed by the 27th of Henry VII. cap. 10. which executes all uſes raiſed; and as this introduced a more ſecret way of conveying than was known to the policy of the common law, the enrollment of the bargain and ſale was made neceſſary by the ſixteenth chapter of the ſtatute. *Cunningham's Law Dict.*

BARGE, a veſſel or boat of ſtate, curiouſly decorated, furniſhed with elegant apartments, canopies and cuſhions, equipped with a band of rowers, and adorned with flags and ſtreamers: they are generally uſed for proceſſions on the water, by noblemen, officers of ſtate, or magiſtrates of great cities: of this ſort we may reaſonably ſuppoſe the famous galley of Cleopatra. There are likewiſe others of a ſmaller kind for admirals and captains of the royal navy, calculated to be eaſily hoiſted into and out of the ſhips to which they belong. Barges are alſo flat-bottomed veſſels of burthen for lading and diſcharging ſhips, and removing their cargoes in a harbour. See LIGHTER, PRAM, KEEL.

BARGE-COUPLES, in architecture, a beam mortiſed into another, to ſtrengthen the building.

BARGE-COURSE, with bricklayers, implies that part of the tiling which projects over without the principal rafters, in all ſorts of buildings where there is either a gable-end, or a kirkin-head.

BARILLA, a ſpecies of pot-aſh, ſometimes called ſoda, and prepared in Spain from a plant called kali. See KALI.

BARING *of Trees*, in agriculture, implies the taking away part of the earth about the roots, that the rain and ſnow water, during the winter, may penetrate further into them. This operation is generally performed in the autumn.

BARK, *Cortex*, the exterior part of trees, correſponding with the ſkin of an animal. The bark of the oak has been long uſed in tanning leather, and even thought eſſential to that operation; but a different ſubſtance has been lately diſcovered, which anſwers the purpoſe full as well, and may be procured at a much cheaper rate; we mean oak ſaw-duſt, or the chips of oak reduced to powder. This valuable ſecret was lately purchaſed by the ſociety for the encouragement of arts, &c. See the article TANNING.

Jeſuits BARK. See the article QUINQUINA.

BARK, in naval affairs, a general name given to ſmall ſhips: alſo a ſhip of three maſts, without any mizen-top maſt: likewiſe a name to diſtinguiſh a veſſel with a broad ſtern, without any figure on the prow or ſtern. See HEAD, TOP-MAST, STERN.

BARKING *of Trees*, the peeling off the rind or bark.

It is neceſſary, in our climate, to perform this operation in the month of May; becauſe, at that ſeaſon only, the bark is, by the great quantity of ſap, ſeparated from the wood.

BARLEY, *Hordeum*, a gramineous, frumentaceous plant, whoſe ſeeds are of the larger ſort, covered with a huſk growing in a ſpike, and the grains bearded.

Cultivation of BARLEY. Some ſow barley upon land where wheat grew the former year; but, when this is practiſed, the ground ſhould be ploughed the beginning of October, in a dry time, laying it in ſmall ridges, that the froſt may mellow it the better; and this will improve the land greatly: then, in March, the ground is ploughed again, and laid even, where it is not very wet; but in ſtrong wet lands the ground ſhould be laid round, and the furrows made deep to receive the wet. When this is finiſhed, the ſeed ſhould be ſhown with a broad caſt, at two ſowings; the firſt being harrowed in once, the ſecond ſhould be harrowed until the ſeed is buried. The common allowance of ſeed is four buſhels to an acre.

It is a very common fault with farmers to ſow too much grain of all ſorts on their land; not conſidering that, if the roots of corn ſtand very cloſe together, there will not be room for them to put out many ſtems; ſo that frequently there is not more than two or three ſtalks to a root; whereas, if the roots were farther diſtant, there might be ten or twelve, and on good land many more. We have counted upwards of ſeventy ſtalks of barley from one root, which was tranſplanted in a garden, where the ground was light, but not rich: and are ſatisfied, by ſeveral experiments, that, where barely is ſown early upon light ground, it ſhould not be too thick; for, if it is rolled two or three times before it ſtalks, the roots, by being preſſed, will ſhoot out a great number of ſtalks; and it will not be ſo liable to lodge with wet, as the barley which is ſown thick; ſo muſt conſequently be drawn up much taller, and have weaker ſtalks.

When the barley is ſown, the ground ſhould be rolled after the firſt ſhower of rain, to break the clods, and lay the earth ſmooth, which will render it better to mow, and alſo cauſe the earth to lie cloſer to the roots of the corn, which will be of great ſervice to it in dry weather.

Where barley is ſown upon new broken up-land, the uſual method is, to plough up the land in March, and let it lie fallow until June; at which time it is ploughed again, and ſown with turnips, which are eaten by ſheep in winter; by whoſe dung the land is greatly improved; and then in March following the ground is ploughed again, and ſown with barley as before.

There are many people who ſow clover with their barley; and ſome have ſown the lucern with barley; but neither of theſe methods is to be commended; for, where there is a good crop of barley, the clover or lucern muſt be ſo weak as not to pay for ſtanding: ſo that the better way is to ſow the barley alone, without any other crop among it; and then the land will be at liberty for any other crop, when the barley is taken off the ground: but this practice of ſowing clover, rye-graſs, and other graſs ſeed, with corn, has been ſo long and univerſally eſtabliſhed among farmers, that there is little hope of prevailing with thoſe people to alter a cuſtom which had been handed down to them from their predeceſſors, although there ſhould be many examples produced to ſhew the abſurdity of this practice.

The time for cutting of barley is when the red colour of the ears is off, and the ſtraw turns yellow, and the ears begin to hang down. In the north of England they always reap their barley, and make it up in ſheaves, as is practiſed here for wheat; by which method, they do not loſe near ſo much corn; and it is alſo more handy to ſtack: but this method cannot ſo well be practiſed where there are many weeds amongſt the corn, which is too frequently the caſe in the rich lands near London, eſpecially in moiſt ſeaſons; therefore, when this is the caſe, the barley muſt lie on the ſwarth till all the weeds are dead: but, as it is apt to ſprout in wet weather, it muſt be ſhook up, and turned every fair day, after rain, to prevent it. When it is carried, it ſhould be thoroughly dry; otherwiſe, if it be ſtacked wet, it will turn muſty; or if too green, it is ſubject to burn in the mow. The common produce of barley is two and an half, or three quarters, on an acre; but ſometimes there have been known four quarters on an acre.

Barley-Corn, the leaſt long-meaſure known in England; it is equal to one third of an inch.

BARNABITES, in eccleſiaſtical hiſtory, a religious order founded in the ſixteenth century by three Italian gentlemen, who had been adviſed by a famous preacher of thoſe days, to read carefully the Epiſtles of St. Paul; and hence they were ſtiled clerks of St. Paul: but acquired the name of Barnabites, from their performing their firſt exerciſe in the church of St. Barnabas at Milan. Their habit is black, and their duty conſiſts in inſtructing, catechiſing, and ſerving in miſſion.

BARNICLE, or ſoland gooſe, in natural hiſtory, a ſpecies of gooſe with a black beak, which is much ſhorter than that of the common gooſe. It is common in the north of Scotland.

Barnicle alſo ſignifies a ſpecies of ſhell-fiſh, often found ſticking to the bottoms of ſhips, rocks, &c.

Barnicles, among farriers, an inſtrument compoſed of two branches, joined at one of the extremities with a hinge. It is put upon the noſe of a horſe, when he will not otherwiſe ſtand quiet to be ſhod, blooded, or dreſſed.

BAROCO, in logic, implies the fourth mode of the ſecond figure of ſyllogiſms.

A ſyllogiſm in baroco has the firſt propoſition univerſal and affirmative; but the ſecond and third, particular and negative; while the middle term is the predicate in the two firſt propoſitions. The following is of this kind:

B a. Every virtue is attended with diſcretion:
R o. Some kinds of zeal are not attended with diſcretion;
C o. Therefore ſome kinds of zeal are not virtues.

BAROMETER, an inſtrument for meaſuring the weight of the atmoſphere, and the variations that happen therein, in order to indicate the changes of the weather.

The word is compounded of βαρος, weight, and μετρεω, to meaſure.

As the air is a heterogeneous fluid, it will vary in its weight as its component parts are different; and alſo according to its different altitudes. Few bodies are lighter than water, which is alſo very eaſily rarified into vapour. Hence it follows, that when the air is filled with aqueous particles it will be lighteſt, as we generally find it is in moiſt rainy weather; and alſo that it will be oftener in this than in a heavier ſtate. Some inſtrument therefore is neceſſary to indicate theſe changes, and ſhew the weight of the air at all ſeaſons; and may be made in the following manner:

A glaſs tube, hermetically ſealed at one end, is to be filled with quickſilver, well defecated and purged of its air. The finger being then placed on the open end, in immediate contract with the mercury, ſo as not to admit the leaſt particle of air, the tube is inverted and carefully immerſed, with the finger on the open end, into a baſon of the ſame prepared mercury; then, upon removing the finger, the mercury in the baſon will join that in the tube; and the column of mercury in the latter will immediately ſubſide to a certain pitch, or altitude, provided the tube be above thirty-one inches long.

Let AB (plate XXIII. *fig.* 1.) be ſuch a tube, thirty-four inches in length, and a quarter of an inch in diameter, hermetically ſealed at A, and open at B; let C D be the baſon of mercury, into which the tube is immerſed in an inverted poſition; E F, the ſurface of the mercury in the baſon, and G H, that in the tube. Now it is very eaſy to conceive that if this whole apparatus were in vacuo, all the mercury in the tube would, as ſoon as inverted and the finger taken away, deſcend into the baſon; becauſe it muſt, as being a heavy body, deſcend towards the center of the earth, till it meets with ſuch an obſtacle as the baſon to obſtruct its motion, and ſupport it.

But ſince the mercury does not totally ſubſide when this is done in the open air, it follows that the column remaining in the tube muſt be ſuſpended by the gravity of the air preſſing on the ſurface of the mercury in the baſon. And ſince the mercury in the baſon is in equilibrio with that in the tube, it is plain, that the weight of the mercury in the tube, and the weight of the air upon every circular area of the ſurface of the mercury in the baſon, equal to the orifice of the tube, muſt be equal: conſequently the weight of the column of mercury, in the tube, is equal to the weight of a column of air of the ſame baſe, and whoſe altitude is equal to that of the atmoſphere; conſequently this column of mercury will always ſhew the gravity of the air by its riſe and fall in the tube, and indicate the various changes that happen in the atmoſphere. This diſcovery was made by Torricelli, an Italian gentleman, and a diſciple of the famous Galileo. It is therefore often called the Torricellian tube, the Torricellian experiment, &c.

Since this ſuſpended column of mercury exactly indicates the gravity of the air at all times, philoſophers have watched its various ſtations with the greateſt attention, in order to diſcover the two extremes of the air's gravity, by obſerving the leaſt and greateſt altitude of this mercurial column, which long experience has at laſt ſhewn to be nearly 28 and 31 inches; the mercury very rarely falling below the former, or riſing above the latter: whence 29 inches and a half is fixed upon as the mean altitude, expreſſing the mean gravity of the air, and may therefore be repreſented by B I; let the greateſt altitude be B I, and the leaſt B K; then will H I, the diſtance between them, be what is called the ſcale of variation.

This ſcale or diſtance being three inches in the perpendicular tube; and it being known that fluids will always have the ſame altitude in a tube of any form or inclination; various artiſts have contrived various methods to increaſe the motion of the mercury, by making it move over a large ſpace: and thus have invented ſeveral different ſorts of barometers, the principal of which we ſhall here deſcribe.

That which is next the upright one, is moſt eſteemed, is called the diagonal barometer, and is repreſented in *fig.* 2. where A B C is a tube hermetically ſealed at C, and immerſed in a baſon of mercury at A. This tube is perpendicular from A to B, where the ſcale of variation begins; but is there bent into the form BC, making an acute angle F B C. This part B C extends to the higheſt limit in the ſcale of variation, viz. I C; and conſequently while the mercury riſes from K to I, in the common barometer, it will move in this form B to C, enlarging the ſcale of variation in the proportion of B C to F B; that is, of the diagonal to the leaſt ſide of a parallelogram.

But this barometer is intended with one great inconvenience, which leſſens its utility. Quickſilver being a very heavy body, and ſupported on the part B C, forming an inclined plane, it muſt have a very conſiderable degree of friction, which will be increaſed in proportion as the part B C is more oblique; and conſequently the very ſmall and nice variation of the air's preſſure cannot be ſo accurately indicated in this, as in the common form. It alſo very often happens, from the inclination of the part B C, that the quickſilver divides into ſeveral parts, and thence frequently requires the trouble of re-filling the tube. This barometer was invented by Sir Samuel Moreland.

M. Caſſini invented another kind of barometer, in order to enlare the ſcale of variation; an invention which was afterwards compleated by M. John Bernoulli. It conſiſts of a tube A C D F, (*fig.* 3.) hermetically ſealed at A, and bent to a right angle at D; whence it has acquired the name of the horizontal rectangular barometer. The mercury ſtands in both the legs from E to B; the ſcale of variation from A to C is made in a larger part; and it is evident, that in moving three inches from A to C, it will move through ſo many times three inches in the ſmall leg D F, as the bore of D F is leſs than the bore of A C; whence the motion of the mercury at E muſt be extremely ſenſible. But the inconvenience here too is, that the mercury is very apt to break off in the leg E, and alſo to run out at the end E. Here is alſo a great degree of friction, and at the ſame time the attraction of coheſion will, from the ſmallneſs of the bore D F, impede the free motion of the mercury.

The pendant barometer is made in another form, conſiſting of a ſingle tube ſuſpended by a ſtring faſtened to the end A. (*fig.* 4.) This tube is of a conical or tapering form, the end A being a little leſs than that at B. It is hermetically ſealed at A, and filled with mercury: then will the mercury ſink to its common ſtation, and admit a length of altitude C D, the ſame with that in the common barometers. But from the conical bore of the tube, the mercury will deſcend as the air grows lighter, till it reaches its loweſt altitude, when the mercury will ſtand from the lower part of the tube B to E; ſo that B E will equal 28 inches: conſequently the mercury will, in ſuch a tube, move from A to E, or 32 inches, if the tube be five feet, or 60 inches long; and therefore the ſcale A E is here above ten times greater than in the common barometer: but the fault of this barometer is, that the tube being of a very ſmall bore, the attraction of coheſion will be very conſiderable, and prove an impediment to that freedom of motion, neceſſary to ſhew a very ſmall variation in the air's weight. This invention we owe to M. Amonton, who publiſhed it in the year 1695.

The wheel barometer, ſo called from its ſtructure, is eaſily underſtood from the figure, where A C D G (plate XV. *fig.* 11.) repreſents the quickſilver in a glaſs tube, having a large round head, or baſs at top, and turned up at the bottom F. Upon the ſurface of the mercury in the bent leg, there is placed an iron ball G with a ſtring going over a pulley C D, and balanced by another weight H, ſuſpended freely in the air. As the ſurface of the mercury at A is very large, and that at G very ſmall, the motion of the quickſilver, and conſequently of the ball G, will at the bottom be very conſiderable; but as the weight G moves up and down, it turns the pulley C D, and that a hand or index K L, pointing to the diviſions of a large graduated circle M N O P; by which means the minuteſt variations of the air are plainly indicated, provided the inſtrument be ſo accurately made that the friction of the ſeveral parts be conſiderable. This is one of the many curious inventions of Dr. Hooke.

Mr. Rowning invented a kind of compound barometer, conſiſting of mercury and water. ABC (plate XXIII. *fig.* 5.) is a compound tube heremetically ſealed at A, and open at C, empty from A to D, filled with mercury from thence to B, and from thence to E with water. Let G B H be a horizontal line, then it is plain from the nature of the ſyphon, that all the compound fluid contained in the part from H to G, will be always in equilibrio with itſelf, be the weight of the air what it will, becauſe the preſſure at H and G muſt be equal. Whence it is evident that the column of mercury D H, is in equilibrio with the column of water G E, and a column of air of the ſame baſe conjointly, and will therefore vary with the ſum of the variations of each of theſe. The great property of this barometer is, that the ſcale of variation may be increaſed *ad infinitum*. But notwithſtanding this property, it will afford the theoriſt more pleaſure than the practical artiſt.

We have already hinted that the common barometer is the beſt inſtrument yet known for meaſuring the gravity of the air: but, in order to its doing this to the greateſt perfection, the following particulars are neceſſary to be obſerved. 1. The tube muſt be at leaſt one quarter of an inch in diameter; one third of an inch is a very proper ſize. 2. The tube ought to be new, clean, and dry within when filled; and in order to this it ſhould be hermetically ſealed at both ends, when made at the glaſs-houſe, one end of which may be cut off with a file, when you intend to uſe it. 3. The diameter of the ciſtern that holds the mercury, in which the open end of the tube is immerſed, ſhould be as large as conveniently may be, that the mercury therein may have nearly at all times the ſame degree of altitude, otherwiſe the index will not be true. 4. The mercury muſt be very pure, and free from any mixture of tin, lead, or other metal. 5. It ought to be purged entirely from air, as it may be by boiling, and filling the tube with it, while nearly boiling hot. 6. The tube muſt be heated before it is filled, to prevent its breaking with the boiling mercury. 7. It ſhould be rubbed very hard, to excite the electric virtue, which will expel the particles of the air from the internal ſurface. 8. There ought to be a nonius, or vernier, applied to the index of the graduated plate, for meaſuring more accurately the riſe and fall of the mercury.

As the principal uſe of the barometer is to eſtimate the gravity of the air at different times, in order to foreſee the alterations of the weather, it will be proper here to add the following particulars relating to the riſe and full of the mercury, as they are the reſult of careful and repeated obſervations.

1. The riſing of the mercury preſages in general fair weather, and its falling the contrary. 2. In very hot weather, the falling of the mercury indicates thunder. 3. In winter the riſing preſages froſt; but in a continual froſt, it indicates ſnow. 4. When foul weather happens immediately after the falling of the mercury, little of it is to be expected; and ſo on the contrary of fair weather. 5. But when the mercury continues to riſe for ſome time before the foul weather is over, a continuance of fair may be expected to follow. 6. In fair weather, when the mercury continues to fall before the rains come on, it preſages a great deal of wet, and probably high winds. 7. The unſettled motion of the mercury denotes uncertain and changeable weather.

From theſe obſervations, it appears, that it is not ſo much the heighth of the mercury in the tube that indicates the weather, as the motion of it up and down; in order therefore to know whether the mercury be actually riſing or falling, the following obſervations may be of uſe. 1. If the ſurface of the mercury be convex, it is a ſign that the mercury is then riſing. 2. If the ſurface be concave, that it is ſinking. 3. If the ſurface be plain, or rather a little convex, the mercury is ſtationary. 4. If the tube be ſmall, ſhake the tube, and if the air be growing heavier, the mercury will riſe about half the tenth of an inch; if it be growing lighter, it will ſink as much.

We ſhall end this article with a ſolution to the following curious and uſeful problem, viz.

Having given the height of the mercury in the barometer at the earth's ſurface, to find the height thereof at any given diſtance from the center of the earth, the law of gravitation being reciprocally as the ſquare of that diſtance.

Let the circle SFH (plate XXIII. *fig.* 6.) repreſent the earth, C the center, S a point upon its ſurface, and CB the given diſtance from the center C, where the height of the mercury is required. Let DE*e* be a curve, whoſe nature is ſuch, that the ordinates AD, BE, &c. are reſpectively as the denſities of the atmoſphere in the points A, B, &c. put $CS=r$ the radius of the earth, $CB=x$, $BE=y$, $Bb=\dot{x}$, unity for the force of gravity, and D for the denſity of the atmoſphere at the earth's ſurface: Then $\frac{r^2}{x^2}$ will repreſent the force of gravity at the point B, and $-y\dot{x}$ the fluxion of the denſity at that point; hence $\frac{-r^2y\dot{x}}{xx}$ is the fluxion of the preſſure of the atmoſphere at the point B; but the denſity being as the compreſſed force, it follows that $\frac{-r^2y\dot{x}}{x^2}$ is as $\dot{y}$, or $\frac{-r^2y\dot{x}}{x^2}=b\dot{y}$, and $\frac{-r^2\dot{x}}{x^2}=\frac{b\dot{y}}{y}$, by taking the fluent of each ſide the equation, we get $\frac{rx+rr}{x}=b\times$ hyp. log. y. But when B coincides with S, then $x=r$, and the expreſſion becomes $2r=b\times$ log. D; from this equation ſubtract the former, viz. $\frac{rx+rr}{x}=b\times$ log. y, and we ſhall have $2r-\frac{rx+rr}{x}=b\times$log. $D-b\times$ log. y, or $\frac{rx-rr}{x}=b\times$ log. $\frac{D}{y}$.

It is found by experiment that the mean denſity of air is to the denſity of water, as 1 to 820; and to that of mercury, as 1 to $13\frac{1}{2}$: whence it follows, that the mean denſity of air is to the denſity of mercury, as 1 to $13\frac{1}{2}\times 820$, or 1 to 11070; conſequently cylinders of air and mercury, of equal baſes, having their altitudes in the ratio of 11070 to 1, are of equal weights, it being well known that the quantity of matter is directly as the denſity and bulk conjunctly.

Let the mean altitude of the mercury in the barometer be taken equal to 30 inches, then will the height of a column of air of equal weight and baſe with the mercury in the barometer be expounded by 11070×30, equal to 332100 inches, or 27675 feet. Suppoſe it were now required to find the altitude of the mercury in the barometer, at a height of 1240 yards above the ſurface of the earth, or, which is the ſame thing, 209958164 feet from the center, here, by taking $r=20995444$ feet, $b=27675$, $D=30$, and $x=209958164$, we ſhall have $\frac{rx-r^2}{x}=27675\times$ log. $\frac{D}{y}$; or, if r be expounded by 1, $\frac{x-1}{x}=,00131\times$log. $\frac{D}{y}$, that is, $\frac{x-1}{,00131x}$, or $135398=$ log. $\frac{D}{y}$, the natural number of which 135398 is the hyperbolic logarithm 1,145: therefore $\frac{D}{y}$ or $\frac{30}{y}=1,145$; from hence we get $y=\frac{30}{1,145}=26,2$, the height of the mercury in the barometer at 1240 yards above the earth's ſurface; which agrees exactly with Dr. Halley's experiment made with a barometer upon the top of Snowdon-Hill, 1240 yards high, where he found the mercury to be lower by three inches eight tenths, than at the foot thereof.

BARON, the next degree of nobility below a viſcount and above a baronet.

Barons *of the Exchequer*, the four judges to whom the adminiſtration of juſtice is committed, in matters relating to the revenues of the crown.

They were formerly barons of the realm; but are generally of late perſons learned in the law. They are obliged by their office to inſpect the king's accounts, and accordingly have auditors under them.

Barons *of the Cinque Ports*, are the members of the houſe of commons ſent by the Cinque ports. See Cinque Ports.

Baron and Feme, a term uſed in our law to ſignify the huſband in relation to his wife, who is called feme. They are conſidered only as one perſon, ſo that a huſband cannot be witneſs for or againſt his wife, nor the wife for or againſt her huſband, except in caſes of high treaſon.

Baron and Feme, in heraldry, is when the coats of arms of a perſon and his wife are borne per pale in the ſame eſcutcheon, the man's being always on the dexter, and the woman's on the ſiniſter ſide: but if the woman be an heireſs, her coat muſt be borne by the huſband on an eſcutcheon of pretence.

BARONET, a modern degree of honour, next to a baron, created by king James I. in order to ſettle a plantation in Ulſter, for which purpoſe each was to maintain thirty ſoldiers in Ireland for three years, after the rate of eight-pence ſterling per day to each ſoldier.

This honour is hereditary, and they have the precedence of all knights, except thoſe of the garter, bannerets, and privy counſellors.

BARONY, the honour and territory which gives title to a baron, whether he be a layman or a biſhop.

BAROSCOPE, the ſame with barometer. See Barometer.

The word is formed from βαρος, weight, and σκοπεω, to view.

BARR. See Bar.

BARRACAN, in commerce, a ſort of ſtuff reſembling camblet, but of a coarſer grain.

BARRACKS, or **Baracks**, places erected for ſoldiers to lodge in, eſpecially in garriſons.

BARRATOR, in law, a common mover or maintainer of ſuits and quarrels, either in courts, or elſewhere.

Lambert derives the word from the Latin, *barathro*, or *balatro*, a vile knave.

BARRATRY, in the marine acceptation, implies a defrauding the owners by the maſter of the ſhip.

BARREL, in commerce, a round veſſel, in the form of a ſmall tun, for holding ſeveral ſorts of merchandize.

Barrel alſo implies a liquid meaſure, and is of three kinds, wine, beer, and ale. The firſt contains thirty-one gallons and a half; the ſecond thirty-ſix gallons; and the third thirty-two gallons.

Barrel likewiſe denotes a certain weight of ſeveral merchandizes, which not only differs in different commodities, but alſo in different places. A barrel of Eſſex butter weighs one hundred and ſix pounds; and a barrel of Suffolk butter two hundred and fifty-ſix pounds. The barrel of herrings ought to contain thirty-two gallons wine meaſure, and will hold about a thouſand herrings. The barrel of ſalmon muſt contain thirty-two gallons. The barrel of eels the ſame. The barrel of ſoap muſt weigh two hundred and fifty-ſix pounds.

Barrel, in mechanics, a name given by watchmakers to the cylinder about which the ſpring is wrapped; and by gun-ſmiths to the cylindrical tube of a gun, piſtol, &c. through which the ball is diſcharged.

Barrel, in anatomy, a pretty large cavity behind the tympanum of the ear, about four or five lines deep, and five or ſix wide. It is lined with a fine membrane, on which are ſeveral veins and arteries. See Ear.

Thundering **Barrels**, in military affairs, are a ſort of caſks, filled with bombs, grenades, and other deſtructive inventions, to be rolled down a breach.

BARRICADE, or **Barricado**, a military term for a fence formed in haſte with veſſels, baſkets of earth, trees, palliſades, or the like, to preſerve an army from the ſhot or aſſault of the enemy.

The moſt uſual materials for barricades conſiſt of pales or ſtakes, croſſed with battoons, and ſhod with iron at the feet; uſually ſet up in paſſages or breaches.

Barricade, in naval architecture, a ſtrong wooden rail, ſupported by ſtanchions, extending acroſs the foremoſt part of the quarter-deck. In a veſſel of war, the vacant ſpaces between the ſtanchions are commonly filled with rope-matts, cork, or pieces of old cable; and the upper part, which contains a double-rope-netting above the rail, is ſtuffed with full hammocks to intercept the motion, and prevent the execution of ſmall-ſhot in time of battle. See Deck, Hammock.

BARRIER, in fortification, a kind of fence made acroſs a paſſage or the entrance of a retrenchment, &c.

It is compoſed of large ſtakes about four or five feet high, placed eight or ten feet diſtant from one another, with tranſums, or over-thwart rafters, to ſtop either horſe or foot. In the middle is a moveable bar of wood, that opens or ſhuts at pleaſure.

BARRING *a Vein*, in farriery, implies an operation performed on the veins of a horſe's legs, and other parts of his body, in order to ſtop the courſe of the blood, and leſſen the quantity of malignant humours flowing to that part. This operation, as it is founded on a falſe theory, ſo it is now never uſed by ſkilful farriers.

BARRISTER, in common law, implies a perſon qualified and impowered to defend the cauſe of clients in any of the courts of juſtice.

The word is formed from the Latin, *bar*, *bara*, the place where they ſtand to plead.

Barriſters are of two ſorts, diſtinguiſhed by the epithets outer and inner. The outer-barriſters are thoſe who plead without the bar. The inner-barriſters are thoſe who are allowed the privilege of pleading within the bar. But at the Rolls, and ſome other inferior courts, all barriſters are admitted within the bar.

BARROW, in ſome ſalt works, is a name given to wicker caſes in the form of a ſugar loaf, wherein the ſalt is put to drain.

BARRULET, in heraldry, ſignifies the fourth part of the bar, or one half of the cloſſet.

BARRULY, in heraldry, is when the field is divided bar-ways, that is, acroſs from ſide to ſide, into ſeveral parts. See plate XXIII. *fig.* 7.

BARRY, in heraldry, is when an eſcutcheon is divided bar-ways, that is, acroſs from ſide to ſide, into an even number of partitions, conſiſting of two or more tinctures, interchangeably diſpoſed. It is to be expreſſed in the blazon by the word *barry*; and the number of pieces muſt be ſpecified; but if the diviſions be odd, the field muſt be firſt named, and the number of bars expreſſed.

BARRY-BENDY is when the eſcutcheon is divided evenly, bar and bend-ways, by lines drawn tranſverſe and diagonal, interchangeably varying the tinctures of which it conſiſts. See plate XXIII. *fig.* 8.

BARRY-PILY is when a coat is divided by ſeveral lines drawn obliquely from ſide to ſide, where they form acute angles.

BARSANIANS, in eccleſiaſtical hiſtory, a ſect of heretics in the ſixth century, who followed the errors of the Cainites and Theodoſians; and were ſo called from one Barſinius their leader.

They made their ſacrifices conſiſt in taking wheat flour on the top of their fingers, and carrying it to their mouths. They never eat meat with other men; and maintained the Holy Ghoſt to be a creature.

BARTERING, in commerce, the exchanging one commodity for another, or ſending a merchant a parcel of goods, and taking others of him in exchange.

The word is formed from the Spaniſh, *baratar*, to deceive, or circumvent; becauſe, perhaps, thoſe who deal this way, endeavour to over-reach one another.

BARTHOLOMITES, a religious order founded at Genoa, in the year 1307; but the monks leading very irregular lives, the order was ſuppreſſed by pope Innocent X. in 1650, and their effects confiſcated.

BARUCH, the name of an apocryphal book, ſubjoined to the canon of the Old Teſtament.

It has been reckoned part of Jeremiah's prophecy, and is often cited by the ancient fathers as ſuch. Joſephus tells us, that Baruch was deſcended from a noble family. It is added, that he wrote the book himſelf, while he continued at Babylon; but at what time is uncertain.

There are three copies of this book, one in Greek, the other two in Syriac: one of the latter agrees with the Greek, but the other varies from it. In what language it was written, whether one of theſe copies be not the original, or which of them may be ſo, is difficult to determine.

BARUTH, an Indian meaſure containing ſeventeen gantans, and ought to weigh three pounds and an half Engliſh averdupoiſe.

BARULES, in eccleſiaſtical hiſtory, a ſect of heretics, who held that the Son of God had only the phantom of a body; that ſouls were created before the world, and that they lived all at one time.

BAS-RELIEVE. See BASSO-RELIEVO.

BASALTES, in natural hiſtory, a ſpecies of marble of a very fine texture, and of a deep gloſſy black colour.

The moſt remarkable quality of this marble is its figure, being never found in ſtrata, like other marbles, but always ſtanding up in form of regular angular columns, compoſed of a number of joints placed on and nicely fitted to each other, as if formed by the hand of a ſkilful workman. It is remarkably hard and heavy, will not ſtrike fire with ſteel, and makes a fine touchſtone.

The giants cauſeway in Ireland is entirely compoſed of the baſaltes; and is, perhaps, the moſt ſurprizing natural production of this kind in the world.

BASE, in geometry, the loweſt ſide of the perimeter of a figure: thus any ſide of a triangle may be called its baſe; but the loweſt, or that parallel to the horizon, is moſt properly the baſe. In the triangle KLM (plate IX. *fig.* 3.) the line KL is properly the baſe.

BASE, in architecture, is uſed to imply any particular body that bears upon another; but particularly for the lower part of a column and pedeſtal.

BASE *of a Column* is that part between the ſhaft and the pedeſtal, if there be any pedeſtal; or, if there be none, between the plinth and the zocle. The ornaments of the baſe, which are ſuppoſed to have repreſented originally the iron circles with which the trees and poſt that ſupported the ancient houſes were bound, are different in the different orders.

The Tuſcan BASE is the moſt ſimple of all others, conſiſting only of a ſingle tore, beſides the plinth. See plate XI.

The Doric BASE has an aſtragal more than the Tuſcan, tho' that was indeed introduced by the moderns.

The Ionic BASE has a large tore over two ſlender ſcotias, ſeparated, according to Vitruvius, by two aſtragals.

The Corinthian BASE has two tores, two ſcotias, and two aſtragals.

The Compoſite BASE has an aſtragal leſs than the Corinthian.

The Attic BASE has two tores and a ſcotia; and is a proper baſe for either the Ionic or Compoſite columns.

BASE *Rudentée*, in architecture, is that which has its tores cut like cables.

BASE, in fortification, the exterior ſide of the polygon, or an imaginary line drawn from the flanked angle of a baſtion to the angle oppoſite to it.

BASE, in gunnery, the leaſt ſort of ordnance, the diameter of whoſe bore is one inch and a quarter, and its weight 200 pounds; the length of the bore is four feet; its ſhot a pound and a half in weight, and one inch and one eighth in diameter.

BASE *Line*, in perſpective, the common ſection of a picture, and the geometrical plane.

BASE *of the Heart*, in anatomy, denotes its upper part. See HEART.

BASE *Eſtate*, in law, implies the eſtate held by a baſe tenure.

BASE *Tenure*, the holding by villenage, or other cuſtomary ſervices.

BASE *Fee* is to hold in fee at the will of the lord.

BASE *Court*, any court not of record.

BASEMENT, in architecture, implies a baſe continued a conſiderable length, as round a houſe, room, &c.

BASHAW, a Turkiſh governor of a province, city, or other diſtrict.

BASIL, in botany, the Engliſh name for a genus of plants called ocymum. See OCYMUM.

BASIL, among joiners, the ſloping edge of a chiſſel, or of the iron of a plane. They uſually make the baſil twelve degrees for ſoft wood, and eighteen for hard; it having been found by experience, that the more acute the baſil is, the better it cuts; and the more obtuſe it is, the ſtronger and fitter for ſervice.

Order of St. BASIL, the moſt ancient of all the religious orders, and was very famous in the Eaſt during the latter part of the fourth century; tho' ſome doubt whether St. Baſil was really the founder.

Some authors, among whom is Barbaroſa, ſay, that

St. Baſil, before he died, ſaw himſelf the ſpiritual father of more than 90,000 monks in the Eaſt only. But this order, which flouriſhed in ſo remarkable a manner for more than three centuries, was afterwards conſiderably diminiſhed by hereſy, ſchiſm, and a change of the empire. The greateſt ſtorm it felt was during the reign of Conſtantine Copronymus, in the year 741, who perſecuted the monks of St. Baſil, impriſoning ſome, and baniſhing others; ſo that the greater part of the monaſteries were abandoned, and ſpoiled of all their goods.

BASILARE *Os*, in anatomy, the ſame with os ſphenoides. See SPHENOIDES.

BASILIC, in ancient architecture, implies a large hall, or public room, with iſles, porticoes, galleries, tribunals, &c. being the term applied to thoſe places where princes ſat and adminiſtered juſtice in perſon.

The word is Greek, βασιλικη, and ſignifies a royal houſe, or palace.

The word is now uſed to ſignify ſuch churches, temples, &c. as far ſurpaſs the other ſtructures of the ſame kind in grandeur and magnificence.

BASILICA, in anatomy, the interior branch of the axillary vein, running the whole length of the arms. See VEIN.

BASILICON, in pharmacy, an epithet given to ſeveral compoſitions to be found in ancient medicinal writers. At preſent it is confined to two officinal ointments, diſtinguiſhed by the epithets black and yellow; and formerly much uſed by ſurgeons in dreſſing wounds.

BASILICS, in antiquity, a body of the Roman laws, tranſlated into Greek. In this ſyſtem is comprehended the inſtitutes, digeſts, code, novels, and ſome edicts publiſhed by Juſtinian and other emperors.

BASILICUS, in aſtronomy, a ſtar of the firſt magnitude, in the conſtellation Leo, called alſo regulus, and cor leonis, or the lion's heart. See REGULUS.

BASILIDIANS, a ſect of heretics in the ſecond century, and ſo called from their leader Baſilides, a diſciple of Menander. He flouriſhed in Egypt about the year 112, and there chiefly propaged his hereſy.

Baſilides, in the creation of things, admitted a certain ſucceſſive ſcale, in which each link of beings created the ſucceeding, and were themſelves created by the preceding; and conſequently, that one being only owed its exiſtence to God. He alſo taught that there were 365 heavens between the earth and the empyrean; and that each of theſe heavens had a moving and creating angel aſſigned to it; which angel was itſelf created by the next angel above him: and hence came the word Abraxas, or magnificent ſaviour. See ABRAXAS.

With regard to the Chriſtian religion, Baſilides taught, that Chriſt did not really ſuffer upon the croſs; but that Simon the Cyrenean was ſubſtituted in his room: that the promiſcuous copulation of men and women was lawful: that a Chriſtian may renounce the faith to avoid martyrdom; and that the ſoul alone is to be ſaved, and the body never to riſe from its ſtate of corruption.

BASILISK, a fabulous kind of ſerpent, ſaid to be produced from a cock's egg hatched by a ſerpent, and ſuppoſed to kill by its breath or ſight only.

BASILISK, in military affairs, implies a piece of ordnance, carrying a ſhot of forty-eight pounds, and weighing about ſeven thouſand two hundred pounds.

BASIOGLOSSUS, in anatomy, a muſcle ariſing from the baſe of the os hyoides, and running along the middle of the tongue towards its apex. It is aſſiſted by the ceratogloſſus, and draws the tongue backwards.

The word is formed from the Greek, βασις, the baſe or foundation, and γλωσσα, the tongue.

BASIS, the ſame with baſe. See BASE.

BASKETS *of Earth*, in the military art, ſignify ſmall baſkets filled with earth, and uſed in ſieges on the parapet of a trench. The French call them *corbeilles*. They are generally a foot and a half high, the ſame in diameter at the top, and eight or ten inches at bottom; ſo that when ſet together, a ſort of embraſures are left at their bottoms, through which the ſoldiers fire, without expoſing themſelves.

BASKET-SALT, a very fine ſalt, much purer, whiter, and compoſed of ſmaller grains than the common ſort.

BASKET-TENURE, a tenure of lands by the ſervice of making the king's baſkets.

BASON, in anatomy; ſee the article PELVIS.

BASON, in mechanics, a term uſed by glaſs grinders for a diſh of copper, iron, &c. in which they grind convex glaſſes, in the ſame manner as concave ones are ground on ſpheres.

The hatters call the iron mould in which they form the matter of their hats, a baſon; and they give the ſame name to the leaden one for the brims of hats; the latter has an aperture in the middle big enough for the largeſt block to go through.

BASON or FOUNTAIN, among gardeners, implies a reſervoir for holding water either for the ornament or uſe of the garden.

Theſe reſervoirs are made in divers forms, ſome round, ſome oblong or oval, others ſquare, octangular, &c. but their moſt common form is circular; and if the ground will permit, the larger they are the better; and when they exceed in ſize, they are called pieces of water, canals, fiſh-ponds, pools, &c.

In making theſe, care ought to be taken to avoid both extremes, and not to make them too big or too little; that a water-work may not take up the beſt part of a ſmall piece of ground; nor to make too little a baſon in a large ſpot. This muſt depend entirely on the judgment of the deſigner of the garden.

Some would have the ſize of a baſon to be proportioned to the jet d'eau, that the water thrown up in the air may not, by being blown by the air, be carried beyond the edge of the baſon, but fall down without wetting the walk.

As to the depth of baſons, they are uſually from two to three feet; this depth being ſufficient to ſecure the bottom of the baſons from froſt, and to dip watering-pots.

But if they are to ſerve as reſervoirs, or to keep fiſh in, then they may be made four or five feet deep, which will both hold water enough for the fiſh to breed in, and alſo to bear a boat.

Deeper than this they ſhould not be; for if they were deeper, they would be dangerous as to the drowning of perſons who might chance to fall in.

In making baſons, great care ought to be taken of making them at firſt; for the water always naturally endeavouring to run away, and by its weight and preſſure in a baſon, making its way out at the leaſt cranny, it will grow conſtantly bigger and bigger; ſo that, if it be not well made at firſt, it will be very difficult to repair it.

Baſons are made either with clay, cement, or lead; they are moſt uſually made of clay: in making ſuch, at the marking out the dimenſions, the diameter ought to be four feet bigger on each ſide; yet the baſon will not be wider; for it will be taken up with the walls on each ſide: and the clay-work, which is to fill the ſpace between the baſon, muſt alſo be dug two feet deeper than the depth of the water is deſigned to be, becauſe it is to be laid over eighteen inches thick with clay, and ſix inches with gravel and paving.

The clay ought to be well wrought with the hands and water; and when it is ſpread, ſhould be trodden in with the naked feet, that the water of the baſon may not dilute through it, and the roots of any trees that may grow near, may not penetrate into the outward wall, which may be made of ſhards, rubble, or flints, with mortar made of the natural earth, and is called the ground-wall, becauſe it is only made to reſiſt the preſſure of the ground about it. The inward wall ought to be made with good rubble ſtones, that will not ſcale and come off in flaſhes in the water; or elſe of flints and ſtones from the hills, which will make durable works, but will not look ſo neat as the pointed rubble; and there ought to be laid here and there ſtones the thickneſs of the wall, to render it the more ſubſtantial.

The method of making baſons of cement is as follows: after you have marked out the dimenſions of the baſon, as before, if you enlarge it one foot nine inches, it will be ſufficient; and the ſame depth deeper at the bottom will be enough.

This being done, you muſt begin to back up and raiſe againſt the ground: cut perpendicularly a wall of maſonry a foot thick, which muſt go to the bottom, and ſhould be built with ſhards and rubble ſtones laid in a mortar of lime and ſand. When the wall is finiſhed round the circumference, then the bottom is to be wrought a foot thick with the ſame materials; and the ſolid work or lining of cement is to be backed up againſt the walls nine inches thick, including the plaiſtering and inward ſurface.

This ſolid ought to be made of ſmall flints, laid in beds of mortar made of lime and cement.

When this ſolid is eight inches thick, it ought to be plaiſtered over the whole ſurface of the bottom, with cement well ſifted before it be tempered with lime; and with this it ſhould be wrought over ſmooth with the trowel.

The proportion of this cement ſhould be two-thirds of cement or powdered tile, to one-third of lime.

This cement has the property ſo to harden under water, that it will be as hard as ſtone or marble, and the body will be ſo ſolid as never to decay.

After the finiſhing of the baſon, the plaiſtering ſhould be for four or five days ſucceſſively anointed over with oil, or bullocks blood, to prevent it from cracking or flawing: this being done, the water ſhould be let into the baſon as ſoon as may be.

Thoſe baſons which are made of lead, are to be thus wrought: the out-lines ought to be enlarged one foot of a ſide, and digged half a foot deeper than the baſon is to be. The wall muſt be made a foot thick, that it may be able to bear up againſt the earth lying againſt it; but the bottom will not require to be more than half a foot thick.

Theſe walls muſt be built with rubble laid in mortar all of plaiſter, becauſe the lime will corrode the lead; and then the lead muſt be laid on the walls and bottom, and be ſeamed with ſolder.

But baſons of lead are not much in uſe, becauſe of their great charge in making, and the danger of the lead being ſtolen.

Great care ought to be taken to keep the upper edge and ſuperficies of a baſon upon a level, that the water may cover all the wall equally.

As for the waſte pipes of baſons, whether at the bottom or ſuperficies, they ought not to be made too ſmall, leſt they ſhould be choaked, notwithſtanding the cauls that are drawn before them.

When this waſte water is only to be loſt in ſinks and common ſewers, it is carried away in drains, or earthen-pipes; but when it ſerves to play the baſons that lie below it, it muſt paſs through leaden pipes.

Theſe baſons are now pretty generally rejected by perſons of good taſte, as being no ways ornamental: therefore, where there is a neceſſity to make reſervoirs for water for the uſe of gardens, they are commonly dug in the loweſt part of gardens, or where the ſpot is moſt convenient for receiving the water which may run from the adjacent grounds in hard rains. Theſe ponds ſhould have their ſides made very eaſy; for if they are too upright, the earth frequently breaks down, by the water waſhing and making it hollow below: the ſides and bottom of theſe ponds ſhould be laid nine or ten inches thick with well-wrought clay; and, as the clay is finiſhed, it ſhould be well covered, to prevent the ſun and wind from cracking it before the water is let in. The figures of theſe ponds ſhould not be regular; for the ſhape of the hollow, where they are made, ſhould be followed, which will ſave expences, and have a better appearance.

BASONS *of a Balance*, the two ſcales or diſhes faſtened, by ſtrings or chains, to the extremities of the beam; one for holding the weights, and the other the commodity to be weighed.

BASS, in muſic, that part of a concert which conſiſts of the graveſt and deepeſt ſounds, and is played on the largeſt pipes or ſtrings of a common inſtrument, as of an organ, lute, &c.

The baſe is the principal part of a muſical compoſition, and the foundation of harmony; for which reaſon it is a maxim among muſicians, that when the baſs is good, the harmony is ſeldom bad; and the contrary.

Counter BASS is a ſecond or double baſs, where there are ſeveral in the ſame concert.

Thorough BASS, or *Baſſo Continuo*, is the harmony made by the baſs viols, theorbos, &c. continuing to play both while the voices ſing, and the other inſtruments perform their parts, and alſo filling up the intervals when any of the other parts ſtop. It is played by figures marked over the notes on the organ, harpſichord, &c. and frequently ſimple and without figures, on the baſs-viol and baſſoon.

M. Broſſard obſerves, that the thorough baſs is a part of the modern muſic; and that it was invented by Ludovico Viadana, an Italian, in the year 1600.

BASSOON, a muſical inſtrument of the wind ſort, blown with a reed. It is furniſhed with eleven holes, and uſed as a baſs in a concert of hautboys, flutes, &c.

BASSO-RELIEVO, or BASS RELIEF, a piece of ſculpture, where the figures do not protuberate, or ſtand out far beyond the plane on which they are formed.

BASS-VIOL, a muſical inſtrument reſembling a violin in the ſhape, but much larger. It is ſtruck with a bow, like a violin, has generally the ſame number of ſtrings, and eight ſtops, which are ſubdivided into ſemi-ſtops. Its ſound is grave, and has a very noble effect in a concert.

BASTARD, a natural child, or one born of a woman not married.

By the laws of England, a baſtard is incapable of inheriting lands, as the heir of his father; nor can any one inherit lands as heir to him, except the children of his own body; for by order of law, a baſtard has no relation, and he himſelf is accounted the firſt of his family.

BASTARDY, a defect of birth, objected to one born out of wedlock, and is either general or ſpecial.

General BASTARDY is a certificate from the biſhop of the dioceſe to the king's juſtices, after enquiry made whether the party is a baſtard or not, upon ſome queſtion of inheritance.

Special BASTARDY is a ſuit commenced in the king's courts againſt a perſon that calls another baſtard.

BASTERNA, a ſort of vehicle reſembling our chariots, much uſed by the ancient Roman ladies.

BASTION, in fortification, a large maſs of earth, uſually faced with ſods, ſometimes with brick, but rarely with ſtone, ſtanding out from a rampart, of which it is a principal part.

A baſtion conſiſts of two faces and two flanks; the faces include the angle of the baſtion, and their union forms the outmoſt, or ſaliant angle, called alſo the angle of the baſtion; and the union of the two faces to the two flanks, makes the ſide angles, called alſo the ſhoulders or epaules; and the union of the two other ends of the flanks to the two curtains, makes the angles of the flanks.

Thus in *fig.* 8. plate XII. the lines HX, RX, OQ, QI, are the faces of the two baſtions X and Q; HN, IP, the flanks of the ſame baſtions; and NP the curtain. The angles RXH, OQI, are the ſaliant angles, or angles of the baſtions; the angles NHX, PIQ, are the ſide angles, ſhoulders, or epaules; and the angles HNP, IPN, the angles of the flanks. The lines AX, AQ, are called the capitals of the baſtions X and Q. Z and Y are two powder magazines; T and W caviliers.

The great rule in conſtructing a baſtion is, that every part of it may be ſeen and defended from ſome other part: mere angles therefore are not ſufficient; but flanks and faces are neceſſary.

The faces muſt not be leſs than twenty-four Rhineland perches, nor more than thirty. The flanks of a baſtion, provided they ſtand at the ſame angle under the line of defence, are ſo much the better the longer they are; they muſt therefore ſtand at right angles with the line of defence. At the ſame time the diſpoſition of the flanks make the principal part of fortification, as on them the defence chiefly depends; and it is this that has introduced the various kinds of fortifying.

The angle of the baſtion muſt exceed 60 degrees, otherwiſe it will be too ſmall to give room for guns, and will either render the line of defence too long, or the flanks too ſhort. It muſt therefore be either a right angle,

or ſome intermediate one between that and ſixty degrees. See FORTIFICATION.

Solid BASTION is that which has the void ſpace filled up entirely, and raiſed to an equal height with the rampart.

Void or *Hollow* BASTION is that which is only ſurrounded with a rampart and parapet, having the ſpace within void or empty.

Flat BASTION is a baſtion built in the middle of the curtain, when it is too long to be defended by the baſtions at its extremities.

Cut BASTION is that whoſe point is cut off, inſtead of which it has a re-entering angle, or an angle inwards, with two points outwards; and is uſed, either when the angle would, without ſuch a contrivance, be too acute, or when water, or ſome other impediment, prevents the baſtion from being carried to its full extent.

Compoſed BASTION is when two ſides of the interior polygon are very unequal, which alſo renders the gorges unequal.

Deformed BASTION is when the irregularity of the lines and angles cauſes the baſtion to appear deformed or out of ſhape.

Demi BASTION is compoſed of one face only, has but one flank, and a demi-gorge.

Double BASTION is that which is raiſed on the plane of another baſtion.

Regular BASTION is that which has its true proportion of faces, flanks, and gorges.

BASTON, in law, implies a ſervant to the warden of the Fleet-priſon, who attends the king's courts with a red ſtaff, for taking into cuſtody ſuch perſons as are committed by the court.

BASTON, or BATOON, in architecture, is a kind of moulding in the baſe of a column, called alſo a tore.

BASTON, or BATOON, in heraldry, is a kind of bend which has only one half of the uſual breadth. It reſembles a truncheon, and is the proper mark for baſtardy.

BAT, in natural hiſtory, a kind of mungrel, or amphibious ſort of animal, partaking both of the mouſe and bird, and flying though without feathers.

The bat, which the Latins called veſpertilio, ſeems to be a medium between the quadruped and the feathered kinds. They lay themſelves up during the winter in the drieſt receſſes of caverns; where, fixing their talons to the roof, they cover their bodies with their wings, and in that poſition ſleep for ſeveral months.

BATABLE *Ground*, the lands which lay between Scotland and England, when the kingdoms were diſtinct, and to which both nations pretended a right.

BATCHELOR, or BACHELOR, a ſingle man, who has never been married.

BATCHELOR was, formerly, a title given to thoſe who had obtained the honour of knighthood; but had not a ſufficient number of vaſſals to carry their banner before them in the field of battle.

BATCHELORS, in the univerſities, are perſons who have attained to the *baccalaureate*, or taken the firſt degree in the liberal arts or ſciences.

BAT-FOWLING, a method of catching birds in the night by lighting large candles, or torches, near the place where they are at rooſt; for, upon beating them up, they fly immediately to the flame, where they are eaſily caught in nets, or beat down with buſhes faſtened to the ends of poles.

BATH, *Balneum*, a ſufficient quantity of water collected in ſome convenient receptacle for perſons to waſh themſelves in, either for health or pleaſure: and is either hot or cold.

Hot BATHS, called by the ancients thermæ, produce the moſt ſalutary effects in a great number of diſeaſes; and owe their origin partly to an admixture of ſulphureous particles, while the water is paſſing through the ſubterraneous canals, and partly to the fumes or vapours exhaling through the pores of the earth, where ſulphur is found either pure or impure, as in coals, amber, iron, nitre, &c.

The principal hot baths in our country, are thoſe at the city of Bath in Somerſetſhire; and thoſe at Buxton and Matlock in Derbyſhire. In the above city are four hot baths: one triangular, called the croſs-bath, the heat of which is more gentle than that of the reſt, becauſe it has fewer ſprings; the ſecond is called the hot-bath, from its being formerly much hotter than the reſt, but was then not ſo large as at preſent: the other two are called the king and queen's baths, and are divided only by a wall; the laſt has no ſpring, but receives its water from the king's bath. Each are furniſhed with a pump to throw out the water upon the patient, where that is required.

Theſe waters abound with a mineral ſulphur; they are hot, of a bluiſh colour, and ſtrong ſcent. They do not paſs through the body like other waters, unleſs ſalt be added, when they purge immediately. At the bottom of theſe baths is found a black mud, which is uſed with ſucceſs in aches and pains. The croſs-bath preys upon ſilver, all of them on iron, but none on braſs.

Theſe baths are found of great uſe in diſorders of the head, as palſies, &c. in cuticular diſeaſes, as the leproſy, &c. obſtructions and conſtipations of the bowels, the ſcurvy, ſtone, and in moſt diſeaſes of women and children. They are uſed as a laſt remedy in obſtinate chronic diſeaſes, where they ſucceed very well if they agree with the conſtitution of the patient.

Cold BATHS were held by the ancients in the greateſt eſteem; and the preſent age can boaſt of abundance of noble cures performed by them, and ſuch as were long attempted in vain by the moſt powerful medicines.

Bathing will always act the part of a diuretic, and plunging over head in cold water, eſpecially in that of the ſea, will do more in the cure of melancholy, madneſs, and particularly that occaſioned by the bite of a mad dog, than any other medicine. There is nothing better adapted to the cure of frigidity, when owing to a former exceſs of venery, than the cold bath. It will alſo contribute its ſhare to the cure of a ſimple gonorrhœa, and fluor albus. It is often ſucceſsful in a palſy; and thoſe who uſe it frequently are little affected with the changes of the weather.

Artificial BATHS are of various kinds, and adapted to various diſorders; ſome are made of cephalic and nervous drugs boiled in light and pure water.

For preparing baths of this kind, we principally make uſe of bay leaves, baum, ſouthernwood, marjoram, wild thyme, roſemary, hyſſop, clary, dried mint, penny-royal, feverfew, and the flowers of camomile and roſemary; all which are put into a bag with the addition of a few handfuls of common ſalt, and a little pot-aſh, and gently boiled in the water. In this medicinal water the patient is to be bathed in a bathing tub. It produces very happy effects in paralytic diſorders, imbecility, and weakneſs of the joints; and proves very ſerviceable to weak, cachectic, and cold conſtitutions; eſpecially in old patients, whoſe ſtrength is impaired, their nerves weakened, and the tone of the ligaments of their joints in ſome meaſure deſtroyed.

Vapour BATHS are where the vapours ariſing from burning ſpirits of wine, or from herbs boiled in wine, water, milk, &c. have immediate acceſs to either the whole body, or ſome particular parts. Theſe warm exhalations are of very ſingular efficacy in promoting ſweat, opening the ſubcutaneous ducts, ſoftening the hardened parts, relaxing ſuch as are tenſe and rigid, and diſſolving viſcous and tenacious humours. Vapour baths are therefore of ſingular ſervice in cold diſtempers, anaſarcas, œdematous tumours, and where the limbs are become paralytic. In that terrible ſpecies of teneſmus which generally accompanies a dyſentery, the ſteams of milk in which elder-flowers have been boiled, afford inſtantaneous relief.

BATH, in antiquity, a meaſure of capacity uſed among the Jews, containing the tenth part of an omer, or ſeven gallons and four pints as a liquid meaſure; or three pecks and three pints as a dry meaſure.

BATHS, in architecture, ſuperb buildings erected by the ancients for the ſake of bathing.

Knights of the BATH, a military order in England, inſtituted according to ſome authors by Richard II. who confined their number to four; but others ſay that it was founded by Henry IV. in the year 1399, and their number limited to forty-ſix.

Their motto is *tres in uno*, alluding to the three theological virtues.

BATH-KOL, the daughter of a voice, a name given by the Jews to one of their oracles. It conſiſts of a fantaſtical method of predicting future events by the firſt words they hear from any perſon's mouth, and which they conſider as a voice from heaven to inſtruct them in the matter they are enquiring about.

BATH-METAL, a mixed metal, conſiſting of copper combined with zinc, and generally called prince's metal. See PRINCE's METAL.

BATMAN, in commerce, a kind of weight uſed at Smyrna, containing ſix okes, of four hundred drams each, which amount to ſixteen pounds, ſix ounces, and fifteen drams Engliſh weight.

BATON, or BASTON. See BASTON.

BATRACHOMYOMACHIA, battle of the frogs and mice, the title of an elegant burleſque poem, commonly aſcribed to Homer.

The word is compounded of the Greek, βατραχος, a frog, μυς, a mouſe, and μαχη, battle.

The cauſe of this battle is the death of Pſycharpax, a mouſe, ſon to Taxartes, who being mounted on the back of Phyſignathus, a frog, on a voyage to her palace, to which ſhe had invited him, was ſeized with fear, on ſeeing himſelf in the middle of a pond, ſo that he tumbled off and was drowned. The mice ſuſpecting that Phyſignathus had ſhaken him off with deſign, demanded ſatisfaction, and, by unanimous conſent, declared war againſt the frogs.

BATTALIA, an army drawn up in order of battle.

BATTALION, a ſmall body of infantry drawn up in order of battle, and ready to engage.

A battalion uſually contains from five to eight hundred men; but the number is not preciſely determined. They are divided into three companies, one of which is grenadiers. They are uſually drawn up with ſix men in file, or one before another. Some regiments conſiſt of one battalion only, while others are divided into four or five.

BATTEN, a name given by workmen to a ſcantling of wooden ſtuff, from two to four inches broad, and about an inch thick; the length is generally very conſiderable, but undetermined.

This term is chiefly uſed in ſpeaking of doors and window-ſhutters which are not framed with whole deal, &c. with ſtyles, rails and pannels, like wainſcot; but appear to the eye as if they were really ſuch, by means of theſe battens, bradded on the plain board round the edges, and ſometimes acroſs them up and down, in different manners, according as the workman would imitate this or that different kinds of wainſcot.

BATTENS *of the Hatches*, amongſt ſeamen, thin, long pieces of board or hoops, nailed along the edges of the tarpawlings which cover the hatches at ſea, to confine them cloſe to the hatch and prevent the water from running off the deck into the lower apartments of the ſhip. The tarpawling is a broad piece of tarred canvas. See HATCHWAY.

BATTERING, in the military art, implies the attacking a place, work, or the like with heavy artillery.

BATTERING-PIECES, are large pieces of ordnance, proper for battering a fortification. See CANNON.

BATTERING-RAM, a machine uſed by the ancients in ſieges, for battering the walls and towers of a fortified place.

The uſe of this machine is very ancient, and the invention of it aſcribed to different people. It was of two kinds, ſlung or unſlung.

The former was compoſed of a large beam of oak, reſembling a ſhip's maſt, of prodigious length and thickneſs, having the end armed with a head of iron proportioned to the body, and reſembling that of a ram, and thence it had its name. This terrible machine, which according to Vitruvius weighed 440000 pounds, was ſuſpended, and equally ballanced, like the beam of a pair of ſcales, with a chain, or a large cable, which ſupported it in the air in a ſtrong frame of timber, which was puſhed forwards, on the filling up of the ditch, to a certain diſtance from the wall, by means of rollers or wheels. The frame was ſecured from being ſet on fire by the beſieged, by ſeveral coverings, with which it was then caſed over.

Plate XIII. *fig.* 1. repreſents the battering ram ſuſpended. 2. The ram. 3. The form of its head, faſtened to the enormous beam by three or four bands of iron, four feet in breadth. At the extremity of each of theſe bands (4) was a chain of the ſame metal, one end of which was faſtened to a hook, (6) and at the other extremity of each of theſe chains was a cable firmly bound to the laſt link. Theſe cables ran the whole length of the beam to the end of the ram (7), where they were all bound together as faſt as poſſible with ſmall ropes. To the end of theſe cables another was fixed, compoſed of ſeveral ſtrong cords platted together to a certain length, and then running ſingle (8). At each of theſe ſeveral men were placed, to ballance and work the machine. 10. The chain or cable by which it hung to the croſs beam (11), fixed on the top of the frame.

The unſuſpended ram differed from this only in the manner of working it: for, inſtead of being ſlung by a chain or cable, it moved on ſmall wheels on another large beam.

BATTERING-RAM, in heraldry, is a bearing, or coat of arms, reſembling the military engine of the ſame name.

BATTERY, in the military art, a parapet thrown up, or formed of faſcines, &c. for covering the gunners, &c. from the ſhot of the enemy.

All field batteries conſiſt of four chief parts, namely, the ditch, the parapet, the platform, and the magazine.

The ditch is uſually dug in the front and ſides, and ſometimes quite round; and ſerves not only to furniſh the earth neceſſary for the parapet, but it alſo prevents the enemy from entering the battery ſo readily as he might otherwiſe do. The ditch in front is commonly eighteen or twenty feet broad, and the depth about ſeven or eight feet; the ſides ſloping towards the bottom, which is about ſix feet wide: but the ditches on the ſides are about ten feet wide, and ſix feet deep. Theſe are the dimenſions uſually given; but the general practice ſeems to be, only to get earth ſufficient for the work, and not mind the regularity of the ditch; for as theſe works in attacks are uſually done by night, the keeping ſtrictly to the aſſigned dimenſions is hardly practicable.

The parapet is generally raiſed about three or four feet diſtant from the brink of the ditch, the ſpace left between, called the berm or foreland, ſerving to lodge the rubbiſh beat down by the enemies ſhot, that it may not fall into the ditch.

The thickneſs of the parapet ſhould be about eighteen or twenty feet, in order to be cannon-proof, and about ſeven or eight feet high, when the enemy has no command above the battery: but if they have a command over this height, the parapet ſhould be raiſed high enough to cover the men when they load the guns.

The length of the parapet depends on the number of guns to be employed in the battery.

Thus, for one gun allow eight yards in length; and ſix yards more for every other gun: ſo two guns have fourteen yards, three guns twenty yards, four guns twenty-ſix yards, &c.

There ſhould be great care taken that the battery be not enfiladed or raked by the enemies cannon: neglects of this kind are often fatal to the officers and gunners, as was well known at the ſiege of Carthagena, anno 1741: but this is eaſily prevented by raiſing at one or both ends of the parapet, a bank acroſs the battery called an epaulement, of the ſame thickneſs and height with the parapet, and about fifteen or eighteen feet long.

The parapet conſiſts of two parts, namely, the wall and the merlons.

The wall is that part of the parapet which is contained in one piece from end to end, and is about two and a half or three feet high.

The merlons are detached pieces of the parapet, leaving openings called embraſures, through which the cannon deliver their ſhot.

The embraſures ſhould, as much as is poſſible, be cut perpendicular to the parapet; therefore the battery ſhould be parallel, or nearly ſo, to the object to be battered: for

direct ſhots have moſt force: and oblique embraſures weaken the merlons, or parts of the parapet ſtanding between the embraſures.

The embraſures are uſually about two or two and a half feet wide on the inſide, and about nine or ten feet on the outſide; whereby the cannon may be traverſed from the right to the left, ſo as to command a pretty large extent in front. The diſtance from the middle of one embraſure to the middle of the next ſhould be about eighteen feet, in order to leave ſufficient room for the working of the guns, and the ſtowage of the ſhot and other neceſſaries.

Platforms are generally laid ſloping towards the parapet nine or ten inches; this carries off the rain, prevents the gun from recoiling ſo much when fired, as it would do if laid level; and, when loaded, it is more eaſily brought to the embraſure.

In temporary batteries, the platforms are made of planks laid acroſs ſome ground timbers or ſleepers: there is uſually a platform made to each gun; it is about eighteen feet long, eight feet broad next the parapet, and about fourteen feet broad at the tail, the intermediate ſpaces between the platforms ſerving for the ſhot and other neceſſaries.

When a platform is to be laid on marſhy ground, firſt lay a floor or two of faſcines; cover theſe with hurdles of twelve or fifteen feet long, and ſix or ſeven broad; on theſe lay a floor of three or four inches of earth, and therein lay the ſleepers, and over theſe the planks.

When a battery is built of ſtone or brick, the platform is generally a flat-ſtone pavement ranging the whole length of the battery: this, on account of its reſiſting the injuries of the weather for a long time, is to be preferred to planks; but, in caſe of a bombardment, ſuch a platform is to be avoided, becauſe the ſhells will not only break the pavement, but alſo, by driving about the broken ſtones, do the troops much miſchief.

The magazine to a field battery is uſually made about fifty or ſixty yards behind the platform: it is a cavity dug in the ground, about four feet deep; the earth whereof is thrown between the pit and the platform; the ſides of the pit are ſometimes planked round to keep it dry, and prevent the earth from crumbling in; and the powder barrels placed herein are covered with hurdles and earth, or tanned hides, to preſerve the powder from wet and fire.

The communication to the magazine is by a ſloping trench beginning to deſcend about five or ſix yards behind the platform; and the earth thrown on that ſide where it will moſt conveniently cover the perſons who remove the barrels of powder from the great magazine to the battery or ſmall magazine.

When there are many cannon in battery, and the ſervice is quick, it is cuſtomary to have to every two pieces a ſmall magazine to hold 20 or 30 barrels of powder: this is placed about 15 or 20 yards behind the platform, and againſt the merlon between the cannon; and as theſe barrels are uſed, they are replaced by others from the great magazine.

At each magazine a centinel is placed to prevent accidents; and to prevent perſons coming into the battery and magazines who have no buſineſs there, a trench is ſometimes dug behind the magazine, and carried into the trenches which communicate between the magazine and battery.

To conſtruct a faſcine BATTERY.—For one gun provide faſcines of 9 feet, 600; of 6 feet, 100; of 3 feet, 120.

And, for every other piece of 9 feet, 400; of 6 feet, 100; or 3 feet, 100; each faſcine being about nine inches thick; and let there be three or four pickets for every faſcine, for many will break in driving.

Trace the limits of the parapet in two parallel lines about eighteen feet diſtant, allowing eight yards in length for one gun, and ſix yards for every other gun; and along theſe lines cut a trench about half a ſpade deep.

Lay a row of nine feet faſcines along one trench, obſerving that their ends be well jammed one into the other, and let each be pegged down with two pickets, drove into the ground till the head is ſunk into the faſcine.
